The year 1917, and indeed the remainder of the war period, was chiefly occupied in developing and bringing to perfection the different operations in which aeroplanes had already been engaged. Fighting in formation was developed until it became a highly scientific operation in which whole squadrons and even larger formations were frequently engaged. Bombing raids were also carried out in formation on a large scale, both by "day bombers" operating from behind the lines upon reserve ammunition dumps, railheads, concentration camps and similar objectives, and by twin-engined "night bombers" working from bases on the coast and far in the rear of the front line upon munition works and industrial centres in the heart of the enemy country itself. Raids of this nature had been carried out by the Germans from 1915 onwards, but it was not until 1917 that the appearance of the large Handley Page machine made retaliation possible; a development which led to the formation of the Independent Air Force on June 6, 1918, for the definite purpose of bombing German munition centres. (See AIR RAIDS.)

In dealing with the use of aircraft with the military forces during the War attention has been confined to operations on the Western Front because the work in other scenes of war was mainly on the same lines, except for such spectacular performances as the wiping out of a part of the Turkish VII. army on Sept. 16, 1918, when it was caught in a ravine and bombed to extinction by relays of British aeroplanes. Nothing has, however, been said of the growth of the kite balloon service, which developed from two naval sections that arrived in France in May 1915, until at the end of the War there was a row of them along the whole line of trenches co-operating with the artillery, for which work they possessed the advantage of rendering possible direct communication by telephone between the observer and the battery.

Operations by Naval Airmen.—The first naval flying operation of the War was a patrol by Parseval Airship IV. during the night Aug. 5-6 of the approaches to the mouth of the Thames. Airships and aeroplanes patrolled the English channel during the crossing of the expeditionary force to France. For the remainder of 1914 the naval air service was chiefly engaged upon bombing operations with land machines from aerodromes on the coast of France upon the Zeppelin sheds at Cologne, Düsseldorf, Friedrichshafen and other points. The navy introduced the kite balloon to the British services and in March 1915 the first kite balloon section left for the Dardanelles in the "Manica," from which ship the balloon was used to good effect in spotting for the battleships engaging the Turkish batteries and ships.

About the same time a programme of "S.S." (submarine scout) airships, for use in patrolling the channel and approaches to the Irish sea, was laid down. By the end of 1914 three seaplane carriers were in commission in home waters, and shortly after the New Year the "Ark Royal," soon followed by the "Ben-My-Chree," left for the Dardanelles. From the "Ben-My-Chree" were launched the seaplanes which made history in attacking and sinking surface vessels by torpedoes dropped from the air. All these vessels carried the seaplanes in their holds and hoisted them out over the side by derricks to start from the water. In July 1915 seaplanes were used on the east coast of Africa in spotting for the monitors engaged upon destroying the German light cruiser "Königsberg." On Nov. 3, 1915, a Bristol scout aeroplane rose from the foredeck of the "Vindex" and thus became the forerunner of the ship aeroplanes subsequently developed.

The autumn of 1915 saw the production of the first "coastal" two-engined type airship, for anti-submarine operations from stations on the east coast. During 1916 aeroplanes of the naval air service were still employed in bombing aerodromes, coastal batteries, docks and also points of military importance, while in the Mediterranean regular anti-submarine and reconnaissance patrols by seaplanes and airships were instituted. In 1917 the navy introduced the Handley Page bombing machine, which made it possible to extend the range of bombing attacks. In home waters a more powerful airship, in the "North Sea" class, was produced and still further increased the length of anti-submarine patrols, while airships and, to a less extent, seaplanes began to accompany for prolonged periods the convoys of merchantmen which were organized by the Admiralty. Progress was made in the development of large flying boats operating from Yarmouth and Felixstowe, which patrolled the southern part of the North sea for submarines and Zeppelins. The principle of carrying aeroplanes in ordinary ships of the navy and flying them from platforms revolving with the gun turrets was introduced, while the torpedo-carrying seaplane was also very considerably developed during this period.

Aircraft versus Submarine.—In 1918 the German submarine campaign reached its height and anti-submarine operations were intensified. Airships accompanied the Scandinavian convoy on the greater part of its journey, while a practically constant supervision was exercised by seaplanes, aeroplanes and airships over the "east coast lane," a narrow belt of water close to the shore to which merchant ships were required to keep for their own protection in their passage up the coast. The covering of approach to port by the use of aircraft undoubtedly contributed materially to the safety of American troop convoys. Aircraft were a potent factor in combating the submarine menace in convoy work as in reconnaissance, in co-operation with surface vessels and direct attack. Kite balloons were also installed on monitors, patrol boats and even battleships as an aid to the location of submarines.

Towards the end of the War the "Furious" appeared in its converted form as a seaplane carrier with a long flying deck on which aeroplanes could land as well as take off. An instance of the production of a special device for a specific purpose may be mentioned in the mounting of a Sopwith "camel" aeroplane on a lighter, towed behind a destroyer, for the purpose of making a surprise attack on a patrolling Zeppelin airship. At the date of the Armistice the British airship service was on the point of producing rigid airships capable of accompanying the Grand Fleet to sea as advance scouts, but the German navy employed Zeppelins for this purpose on many occasions and throughout the War maintained a patrol of the North sea which helped them to receive early warning of the movements of the British fleet. (See CONVOY.)

United States.—In April, 1917 there was almost an entire absence of aviation interest and of aviation industry in the United States. The total number of military aeroplanes possessed by the Government at this time amounted to about 60 and none of these was equal to those commonly employed in European service. The entire personnel of the air services of the Army, Navy and marine corps then amounted to about 100 officers and 1,300 men. But immediately upon entering the World War aviation became an active party to the extravagance in funds and the confusion of effort incidental to America's complete lack of military preparation. A chief difficulty was found in the quantity production of aviation materials. Models were obtained and attempts made to copy the latest war aeroplanes but, due to a lack of understanding of the aviation problem, an optimistic scale of production which unhappily could not be met was mapped out.

Due to a great abundance of man-power, the personnel problem was better handled. Training of pilots was begun and carried out on an extensive scale in accordance with advice supplied by officers of the Allied forces. Nineteen months after entrance into hostilities, the membership of the army air service totalled nearly 200,000, of which over 78,000 were in France, England and Italy. A large number of American pilots were received into the air services of England and France, where they served with distinction. On four fronts the United States was represented by over 1,400 pilots, 750 observers and 250 balloon observers.

Naval and marine aviation, like that of the air service of the army, grew to a strength of some 7,000 officers and 33,000 men at the time of the Armistice. Of these, over 17,500 were sent abroad, manning 15 coastal aviation stations in France, two stations in England, five in Ireland and three in Italy. In addition, a strong bombing group was formed and conducted operations in northern France. The work of constructing air stations on the shores of foreign countries was successfully accomplished and constituted a definite deterrent to the activities of the U-boat. In addition, they supplied protection to the American troop-ships.

Immediately following the Armistice, most of the naval barracks and air station equipment were moved into the devastated regions of northern France, and were placed at the disposal of the commission for the relief of Belgium. From salvaged materials shelters were erected for the repatriated and destitute population by American sailors, who constituted the first organized unit to be employed after the war in humanitarian work in this region.

AIRD, SIR JOHN, 1ST BART. (1833-1911), British engineer, was born in London Dec. 3, 1833, the only child of John Aird, contractor for gas and water plants. He joined his father's business at 18, and was entrusted with the removal of the Crystal Palace buildings from Hyde Park and their re-erection at Sydenham. He took part in many enterprises, such as the Hampton and Staines reservoirs, the waterworks of Amsterdam, Copenhagen, Moscow, Bahia, Pará, Calcutta, Simla and Berlin, and later (in the joint firm of Lucas and Aird, afterwards John Aird and Co.) St. John's Wood railway, Hull and Barnsley railway and docks, the W. Highland railway and the great Aswan dam across the Nile. He represented N. Paddington in Parliament as a Unionist from 1887 to 1905, and was its first mayor in 1900. In 1901 he was created a baronet. He made a fine collection of pictures by British painters, the illustrated catalogue to which was printed in 1884. He died at Beaconsfield, Bucks., Jan. 6, 1911.

AIRD, THOMAS (1802-76), Scottish poet, and journalist, was born at Bowden, Roxburghshire, on Aug. 28, 1802, and died at Dumfries on April 25, 1876. In 1848 he published a collected edition of his poems, which met with much favour. Carlyle said that he found in them "a healthy breath as of mountain breezes." Among Aird's friends, besides Carlyle, were De Quincey, Lockhart, Stanley (afterwards dean of Westminster) and Motherwell.

See a *Life* by J. Wallace prefixed to the 5th edition (1848) of his *Poems*.

AIRDRIE, burgh of barony, municipal and police burgh, Lanarkshire, Scotland. Pop. (1931) 25,954. It is 11 m. E. of Glasgow by the L.N.E. railway, and connects with Glasgow by

the Monkland Canal, as well as by the L.M.S. railway via Coatbridge and Whifflet. The canal (constructed 1761-90) connects with the Forth and Clyde Canal near Maryhill. Airdrie was a market town in 1695, but owes its prosperity to coal and iron beds. Other industries are iron and brass foundries, engineering, and cotton manufactures. The burgh was the first town in Scotland to adopt the Free Library Act. Airdrie unites with Coatbridge in sending one member to parliament. The parish of New Monkland, in which Airdrie lies, was formed (with Old Monkland) in 1640 out of the barony of Monkland, land granted by Malcolm IV. to the monks of Newbattle.

AIRE, a town of north France, on the Lys, in the department of Pas-de-Calais, 12m. S.S.E. of St. Omer by rail. Pop. (1926) 4,292. The town lies in a low and marshy situation at the junction of three canals. In the middle ages Aire belonged to the counts of Flanders, and a charter (1188) is still extant. It was given to France by the Peace of Utrecht (1713). The church of St. Pierre (15th and 16th centuries) shows three stages of Gothic architecture. The hôtel-de-ville is 18th century. Aire has considerable trade in agricultural produce. In the World War it was one of the headquarters of the British Army (1917-18).

AIRE, a town of south-west France, in the department of Landes, on the Adour, 22m. S.E. of Mont-de-Marsan on the railway between Morcenx and Tarbes. Pop. (1926), 1,913. Aire (*Atura*, *Vicus Julii*) was the residence of the kings of the Visigoths, and there Alaric II. (*q.v.*), drew up his famous code. It is the seat of a bishopric (5th century) and has a cathedral (12th century) and an episcopal palace (11th, 17th and 18th centuries). Both have been restored. The church of St. Quittierie in Mas d'Aire, a suburb, is a building of the 13th and 14th centuries, with a choir in the Romanesque style, and a fine western portal now much disfigured. The crypt contains several Gallo-Roman tombs and the sarcophagus (5th century) of St. Quittierie.

AIR-ENGINE. The practical drawbacks to employing air as the working substance of a heat-engine are so great that its use has been very limited. Such attempts as have been made to design air-engines on a large scale have been practical failures, and are now interesting only as steps in the historical development of applied thermodynamics. In the form of domestic motors, air-engines had some application, prior to the development of the internal combustion engine and the extended use of electricity. The type survives in a few motors of very small power. One of the chief practical objections to air-engines is the great bulk of the working substance in relation to the amount of heat that is utilized in the working of the engine. Another is the difficulty of getting heat into the working air through the walls of the containing vessel. Air takes up heat from such a surface with much less readiness than does water.

The waste of heat in the chimney gases is accordingly greater; and further, the metallic shell is liable to be quickly burned away as a result of its contact at a high temperature with free oxygen. The temperature of the shell is much higher than that of a steam boiler, for in order to secure that the working air will take up a fair amount of heat, the upper limit to which its temperature is raised greatly exceeds that of even high-pressure steam.

A form of air-engine invented in 1827 by the Rev. R. Stirling is of special interest as embodying the earliest application of what is known as the "regenerative" principle, namely, the principle that heat may be deposited by a substance at one stage of its action and taken up again at another stage with but little loss,

and with a great resulting change in the temperature of the substance at each of the two stages in the operation. The principle has since found wide application in metallurgical and other operations. In any heat-engine it is essential that the working substance should be at a high temperature while it is taking in heat, and at a relatively low temperature while it is rejecting heat.

An attempt to develop a powerful air-engine was made in America about 1833 by John Ericsson, who applied it to marine propulsion in the ship "Caloric," but without permanent success. Like Stirling, Ericsson used a regenerator, but with this difference, that the pressure instead of the volume of the air remained constant while it passed in each direction through the regenerator.

(J. A. E.)

AIREY, RICHARD AIREY, BARON (1803-1881), British general, served in the Crimean War as quartermaster-general to Lord Raglan. He was recognized in the army as one of the best men on the staff, but public opinion held him responsible for the failures of the commissariat. Airey demanded an inquiry in which he completely cleared himself. He was governor of Gibraltar (1865-70), was promoted full general in 1871, received a peerage in 1876, and in 1878-80 presided over the commission on army reform.

AIR FORCES. The World War provided a powerful stimulus to war flying, and great advances were made in technical equipment and experience. This intensive development led to constant changes in the practice and application of flying, so that when peace came it was expected that progress would be as rapid as in wartime. This led to a hesitancy on the part of most nations to commit themselves definitely to a rigid line of policy in aviation matters. The tendency was to wait for what the future disclosed rather than to base programmes of development entirely upon past experience.

The nations therefore shaped their aeronautical policies with an open mind, and in most cases refrained from radical adjustments and expedients which progress to date might have suggested as desirable. What in externals appeared stagnation was not necessarily so. Every forward step, if it is to be sure, must be preceded by much research and experiment before it is presented as a concrete achievement.

Analysis of available data, research and experiment, although less apparent, equals in importance the more tangible evidence of aeronautical progress. A policy readily adjustable to whatever changes the future may bring; an elastic organization that lends

itself readily to expansion; adequate provision for research and experiment; training facilities; a husbanding of the resources, industries and trades that subserve the needs of aviation, and the national attitude towards flying give a truer perspective of potential air power than mere numbers of machines. Policy and organization are the most important criteria.

Two Theories of Control.—Two different schools of thought exist in regard to the general principle that should govern the organization, administration and development of air forces. One school regards flying as a science that can best be applied to war uses by entrusting armies and navies with its adaptation to their own respective needs. Aviation is, accordingly, constituted a component of these services, and its application in war is governed by naval and military considerations. Although this system has certain advantages, in that it grafts a novel instrument of war upon an existing stem and so avoids the disadvantage of setting up an entirely new organization, there is no doubt that it exerts a limiting influence. The soldier and the sailor naturally approach aviation from the angle of their own profession.

Such advances as are made are likely to follow divergent courses. An apparently inevitable spirit of competition between armies and navies also leads to duplication and tends to deprive effort of its full measure of results. The other school considers that the air merits a profession of its own, and that untrammelled devotion to the science and art of flying is necessary to do full justice to possibilities, not only in relation to war but as a factor in modern life. It accordingly seeks to concentrate all aeronautical effort into one main channel, with branches to the various departments which flying can serve.

Unity of Air Control.—Great Britain was the first to gather together the threads of aeronautical activity and place them in the hands of a central authority; and at the beginning of 1918 the air branches of the Admiralty and War Office departments were amalgamated into the Air Ministry. In April 1918, the flying branches of the navy and army were merged into the Royal Air Force. The idea was not a new one, and, although the impulse of war made obstacles easier to overcome, it was not in war that the conception had its origin. The sub-committee of the Committee of Imperial Defence, charged in 1911 with the study of aviation in its relation to defence, mentioned in its report that such a step might be desirable when flying was more advanced. The germ of the idea is also to be found in the constitution of the Royal Flying Corps, formed in 1912, with its naval and military wings. In this instance, however, the measure was too far in advance of the time to survive inter-service jealousies, and shortly before the outbreak of the World War the Royal Naval Air Service was formed, the Royal Flying Corps becoming part of the army.

As air warfare grew in volume and importance, the defects of the dual system under war conditions became more and more apparent. Full use of the nation's resources was prejudiced, and civilian ministers were not only denied unanimous advice on air matters, but were sometimes forced to choose between discordant views and to settle vital differences of opinion. The drawbacks of this competitive system were particularly glaring in the matter of technical supply. Improvement was sought in the principle of joint naval and military Air Boards to co-ordinate supply for the two air services. These boards had, however, no executive control over policy, and achieved but little. Finally the Air Ministry was brought into being as the only apparent alternative to the existing evils.

Although a war measure, the Air Ministry survived the peace, and administers not only the Air Force but controls civil aviation as well. It was, however, not allowed to continue its existence as a department of State without considerable hostility and adverse criticism. Its chief opponents were the navy and army. With their establishments reduced to a minimum, and their budget grants diminishing every year, the older fighting services viewed with misgiving the allotment of funds to the newcomer. They argued that the main use of aircraft in war is to assist directly or indirectly the army and the navy, and that accordingly these services should have entire control of their respective air arms. The reply to this objection is that the conquest of the

air has disclosed possibilities which transcend the scope of land and sea warfare; that to narrow the viewpoint to naval or military problems is to bring their possibilities into a false perspective; and although that aerial assistance to the forces that fight upon the sea and on land is necessary, this need by no means marks the limit that should be set to aerial operations. Moreover, to regard the air merely as an auxiliary to the sea and the land is a dangerous doctrine, since circumstances may render naval and military operations secondary to those carried out by air forces. Another criticism was that a separate air force is extravagant, since it involves additional overhead expenditure. The reply is that this is offset by the economy achieved in having a single authority dealing with air matters.

One result of recognizing aviation as a profession in its own right has been a breakaway from traditional practice in policing the British mandates in the East. Security in these territories is the responsibility of the Royal Air Force; aeroplanes are recognized as the chief instruments for the support of law and order, and military forces are used as auxiliaries. The measure has been justified by the great economy achieved. The development of this conception and its successful application would not have been possible without an Air Staff. Another result is a reversal of principle governing the air *vis-à-vis* the land and sea forces in the defence of Great Britain against air attack. Instead of dividing the air into two portions, one above the land and the other above the sea, and making the army and navy responsible for their respective spheres, the air is regarded for purposes of national defence as a single field of activity. The Air Force is accordingly responsible for guarding against air attack, and such ancillary ground forces as may be necessary conform to air defence measures.

Italy (*q.v.*) was the first of the Great Powers to follow the lead of Great Britain in establishing a separate Air Force. This step was taken in 1923 as a result of Signor Mussolini's assumption of power. The decayed state into which the air services had fallen helped to facilitate a complete reconstruction on new foundations, and under the impulse of Signor Mussolini's keen interest in air questions, Italy has rapidly risen to be one of the most efficient and active air Powers of the present day.

In 1928, under pressure of public opinion following repeated accidents, and in particular the death of the minister M. de Bokanowski in an accident, France followed the example of Great Britain and Italy in unifying the control of her air activities under a separate ministry.

Aviation in Peace and War.—Since it is sometimes claimed that a true appreciation of a nation's air strength cannot be reached without taking into consideration the civil aspect of flying, it is desirable to note the relationship existing between the peace and war sides of aviation. Air strength is represented by air forces maintained in peace, ready to function the moment war breaks out. Heavy losses in life and equipment are, however, to be expected in air warfare, especially if the belligerents are at all equally matched. Air power will, therefore, depend ultimately upon the means available for rapidly making good these losses—that is to say, upon a reserve of flying personnel and on a healthy aircraft industry. It is in respect of these two important factors that civil aviation must make its contribution to a nation's air strength. Hence the practice of granting Government subsidies to commercial air transport enterprises. It may, however, be a long time before civil aviation will occupy, in relation to air strength, a position analogous to that occupied by the mercantile marine in relation to British naval strength.

The requirements of civil and war flying differ considerably. For commerce, economy in running and maintenance and paying load are the factors that count most. For war, speed, climbing power, the carriage and use of armament, and fighting qualities in general are the chief factors that control design. Consequently, apart from the fact that they connote an aircraft industry and the existence of a potential reserve of pilots, aeroplanes used for civil purposes do not contribute directly to a nation's strength in the air.

Details of the various air forces or air arms and the system of

control and organization in the different countries, are given under the heading of each country, as part of the section on *Defence*.

(A. W. H. E. W.)

UNITED STATES

When in April 1917 the United States entered the World War, but little had been done by the country toward the creation of an air component for either the army or the navy. The aviation personnel consisted of 65 officers and 1,120 men in the army, 35 officers and 163 men in the navy. There were on hand no planes but those used for training, and of these only about 300, some of which were of inferior types. Aviation in the army was then a function of the Signal Corps, whose prime mission was to provide means of communication, telephone and telegraph systems in the theatre of military operations. In the navy there was no well defined agency charged with the development of aviation. During the war the aviation section of the Signal Corps was abolished and instead there was created in the United States under the War Department, the division of military aeronautics, while in France the air component of the army was organized as the Air Service, with an officer, chief of the Air Service, in charge. In the navy, in March 1918 aviation was placed under the chief of naval operations, and was administered by an officer called the director of naval aviation.

At the Armistice in Nov. 1918 the army aviation personnel consisted of 20,000 officers, 600 cadets and 164,000 men; that of the navy, 6,716 officers and 30,692 men. There had been delivered in the United States about 8,500 training planes; there had been built for the army some 3,300 service type observation planes, the so-called De Haviland 4's, for the navy 1,600 anti-submarine flying boats, while 15,700 motors for training planes and 13,396 Liberty motors had been produced. The Liberty motor development was one of the most strikingly successful projects undertaken during the war. Service type aircraft, that is, those actually used in military operations, were frequently and greatly changed, modified and improved during the war. This was especially true of the smaller, single-seater pursuit or fighting planes. Acting upon the best advice obtainable, the production efforts of the United States were concentrated upon planes of the larger types mentioned above which were not likely to be superseded so quickly, and upon the production of motors.

Post-War Problems.—The close of the war found the United States with large numbers of these war-built planes and motors on hand, but military aviation had developed so that planes of other types, pursuit, bombing, attack, were absolutely necessary with which to equip the properly organized and constituted air components of its military forces. The possibilities and the importance of commercial aviation were also forcing recognition, and this from both the economic and the national defence standpoints. Planes for all these purposes had to be designed, tested and then built in larger and larger numbers. The designs of both planes and motors were constantly being improved, and there was the danger that if quantity production were undertaken too quickly, those thus turned out would be too soon rendered obsolete. It was decided, and no doubt correctly, to make use of the planes and motors on hand while devoting the major effort and the larger part of the funds, as they became available, to the progressive development and perfecting of planes and motors built according to new and better designs. The result of this policy was that at the end of June 1928 planes and motors designed and built in the United States were at least as good as any produced elsewhere, and furthermore they could be manufactured in quantities in relatively short periods of time.

In addition to airplanes, lighter-than-air craft, dirigibles or airships, are employed in both military and commercial operations. These are in use in both the army and the navy, though their development has been carried on more extensively by the latter service. Congress in 1928 authorized the navy to contract for two airships, each of about 5,000,000 cu.ft. capacity, at a cost of about \$8,000,000.

The best way in which the air effort of the United States should be organized and administered has been much discussed. There were those who advocated the creation of a department

of aeronautics, under a cabinet officer, charged with the conduct of all aviation activities, military and civil. Others urged the setting up of a department of national defence, with a cabinet officer at the head, and under him three assistants in charge respectively of the land, the sea and the air forces. Still another view advanced was that the air components of the army and navy should remain separate, each under the control of the corresponding department head, and up to 1928 this view prevailed. Naval aviation, under the secretary of the Navy, is administered by the bureau of aeronautics, created in 1922, with a navy officer as its chief. Army aviation was made a separate combat arm, called the Air Service, by act of Congress in June 1920. This organization is under the secretary of War, an army officer its chief. In 1926 the name was changed to the Air Corps. In that year, 1926, Congress created in the Department of Commerce an aeronautical section charged with all matters concerning civil or commercial aviation, with an assistant secretary of Commerce at its head, and also provided additional assistant secretaries of War and of the Navy, each to have charge of aviation, under the secretary, in his own department.

During the session which ended July 2, 1926, Congress adopted definite continuing programmes to govern the development of army and navy aviation during the following five-year period. The necessary money was not appropriated until the next session, so that the carrying out of these programmes could not be started until July 1, 1927. In accordance with this legislation, it was intended that by June 30, 1932, the Army Air Corps should have a total of 1,518 officers and 16,000 men, and 1,800 airplanes of the most modern designs, with provision for annual replacements of about 400 planes; the navy, 850 officers and 12,000 men, with not less than 1,000 planes, likewise of up-to-date designs.

As of June 30, 1928, the Army Air Corps consisted of 1,016 officers, 9,494 men, with 511 post-war built planes; the navy of 750 officers, about 10,000 men, with 428 such planes; a total for the United States of 1,766 officers, 19,494 men, and 939 service type planes. Training planes are not included in these figures.

(M. M. P.)

AIR-GAS, air carburetted with the vapour of a highly volatile hydrocarbon, such as petrol (gasolene). This product, originated about half a century ago, can be generated in a simple plant, operated by weights on a small scale, or by shafting, electric motor, or water-power for greater capacities, with self-regulation according to the quantity of gas consumed. About 500 cubic feet of air-gas may be produced from a gallon of good petrol, one cubic foot giving 16 candle-power per hour. A special spirit, which leaves practically no residue, is used. Benzene may also be used.

The figure shows a simple weight-driven apparatus. As the weight descends it pulls the cord wound around the drum of the machine, chain-connected to a wheel inside the casing, standing upon the petrol tank. The wheel has cups that pass through the petrol, pick it up in measured quantities, and discharge it through a pipe into the obliquely-set carburettor. This compresses and carburets the air, using an archimedean screw that rotates and prevents irregular carburation, due to the cold produced by the rapid evaporation of the petrol. Cessation of action automatically occurs from the fact of a vacuum being set up when the bell of the gasholder has risen to a certain height. The machine thus generates rapidly or slowly according to the number of burners in use, and stops if they are all turned off. The larger electrically-driven outfits will produce as many as 2,250 cu. ft. per hour.

A product called gas-machine gas is used in America for making air-gas. Gas-machine gas is a special "cut" or fraction of natural gasolene. This last-named product is isolated from the majority of natural gas produced in America by compression and cooling, or either by oil absorption or charcoal adsorption and subsequent heating. From the natural gasolene thus produced, the gas-machine gas is obtained by a well-controlled distillation, to ensure having a highly volatile material with no residue when carburetted.

Air-gas, commonly known in America as gasoline-gas, consists of air charged with gasoline vapor to a point in excess of the

WORKING DIAGRAM SHOWING THE OPERATION OF A GAS GENERATOR
The action of the weights turns the drum, which rotates the carburettor and the gasoline feeder by means of the bevel gear. The gas thus produced passes into the holder

maximum percentage which can form an explosive mixture. It is widely used for isolated plants in villages and country houses for lighting and other purposes. It is rarely used in larger communities. The mixture commonly found most desirable (for a flame source in the Welsbach burner) is about 6 gallons of gasoline per thousand cubic feet of air. The illuminating power of such air-gas compares favorably with that of ordinary commercial gas. The following table shows theoretical combining proportions for various gases (used as fuels) at room temperature:

Limits of Proportion for Explosive Air-Gas Mixture
(percentage of gas in the mixture by volume)

Gas	Combining proportions	When air is in excess	When gas is in excess
Acetylene	7.9	3.35	52.3
Coal Gas	6.7	18.4
Illuminating Gas	7.9	19.1
Benzene	2.7	2.65	6.5
Gasolene { 86° Be	1.54	4.76
{ 71° Be	1.54	4.76
{ 65° Be	1.31	4.76

AIR-GUN, a gun in which the force employed to propel the bullet is the elasticity of compressed atmospheric air. It has attached to it, or constructed in it, a reservoir of compressed air, a portion of which, liberated into the space behind the bullet when

the trigger is pulled, propels the bullet from the barrel by its expansion. The common forms of air-gun, which are merely toys, are charged by compressing a spiral spring, one end of which forms a piston working in a cylinder; when released by a pull on the trigger, this spring expands, and the air forces out the bullet.

AIR-HOIST. In factories and other places where a supply of compressed air is available, its use for operating lifting tackle

WORKING PARTS OF AN AIR HOIST
The hoist is suspended from the eye at the top and the load is slung on the hook. The piston is shown at the top of the chamber, it having been forced upwards to the full length of its stroke by the pressure of the air from below

is much favoured, because of the cleanliness, absence of noise, and ease of connection with flexible hose. The direct hoist, raising a load 4 or 5 ft., and dealing with from 1 to 70 cwt. in different sizes, is the simplest. It comprises a cylinder, a piston, a rod attached thereto and carrying the lifting hook at the bottom, and an operating valve, controlled by pendent chains. An eyebolt at the top affords means of suspension to a fixed beam, or a swinging jib, or to a trolley running on a girder, either stationary or forming part of a jib or travelling crane.

The hoist shown in the diagram is controlled by balanced pressure. The full air pressure of 80 lb. per sq. in. is maintained at the underside of the piston throughout all the operations of lifting, lowering and remaining stationary. For lifting, the attendant manipulates the valve so that air leaks off the top piston.

Another way of applying air power is to use a special pulley block to which is attached a small pneumatic motor, the cylinders of which actuate connecting-rods and so drive a crankshaft, this being geared to the rope drum in order to gain power. Loads up to 10 tons can be lifted in this way.

For colliery service, another class of air-hoist is built, a winch or haulage engine, the rope drum being driven through gears from a pneumatic motor. This is essential in circumstances where compressed air is the power supply in use. Some of the engines can be run either with air or steam.

AIR-LIFT, a system of lifting liquids by compressed air without a pump. For Artesian-wells the method consists in carrying down a smaller air-pipe either within the water delivery pipe or alongside it, and connecting up an air-compressor. The compressed air forms with the water a mixture of lower specific gravity than the surrounding water in the well or bore-hole, with the result that the mixture of air and water in the tube is forced by the weight of the surrounding water to the point of discharge (*see overleaf*). When the supply flowing into a well is not enough to give constant working, waste of energy may be avoided by a governor. Some air-lifts yield as many as 285,000 gals. per hour per well.

The Shone ejector, another form of air-lift, is utilized for raising sewage and other liquids automatically from one or any number of points, and forcing to any spot desired. The difference between this and the well lift just described is that the liquid gravitates into a bell-shaped casting through an inlet pipe and rises until the vessel is nearly full. Then the air trapped up at the top becomes slightly compressed, and acts on a metal cup that lifts a valve and admits a supply of compressed air into the vessel. This drives the sewage out through an outlet pipe to reach a higher level or any distance away; a fresh supply enters

through the inlet pipe, which has been automatically closed during the discharge, and the cycle commences again.

AIR-LOCK, a steel-plated chamber provided in a tunnelling shield or a caisson (*qq.v.*), to prevent the escape of compressed air during the passage of workers. The pressure in the caisson may be 25 to 30 lb. per sq.in., though higher pressures have been used. A steel door at each exit of the lock provides for the safe passage of men or material, one being opened while the other is shut. There will be several locks in a tunnel shield and in some big caissons. The diagram indicates the shape of a caisson, sunk to make the foundation for a bridge pier, two shafts for material and one for men being fitted. The shaft down which concrete is shot has its air-lock placed lower than those of the other shafts, because the concrete-mixer happens to be located on the lower platform.

Air-lock also means the trapping of air in a bend; *e.g.*, of a water or petrol supply, stopping the flow.

AIR LOG or AIR DISTANCE RECORDER, an instrument which measures the distance flown by an aeroplane relative to the air. It consists of two units: a transmitter which is installed on a wing strut or in some other position on the aircraft where it receives undisturbed air, and an indicator which is mounted on the instrument board. The transmission may be either pneumatic or electric.

The transmitter comprises an impellor or wind-mill, which revolves as the aircraft moves through the air, the number of revolutions being proportional to the air distance travelled. The motion of the impellor is reduced by gearing to actuate a valve

THE OPERATION OF AN AIR LIFT
The diagram shows water being forced up from a well by compressed air. Although chiefly supplied to wells and for lifting sewage, the method can be also used for moving acids, sludges, slimes and heavier liquids

THE USE OF AIR-LOCKS IN CONNECTION WITH A BRIDGE CAISSON
The usual air pressure in caissons is 25 to 30 lb. per sq.in. and steel locks are provided for each shaft. Excavated material is raised by power and, at great depths, cages are used to bring workers to the surface. Under the high pressure work becomes laborious and every effort is made to minimize the worker's fatigue

or contact at a predetermined unit of distance, the resulting impulse of air or electric current operating a ratchet in the indicator. The latter unit is simply a counter. By properly relating the pitch of the impellor blades and the gearing, the instrument will record

any unit of distance, such as geographic miles, nautical miles or kilometres. The instrument is rendered inoperative below a predetermined minimum speed, in the pneumatic type by relating the air pressure to the speed in such a way that operating pressure is not available below the minimum speed, and in the electric type by using a centrifugally controlled switch. This protection is necessary to prevent the operation of the air log by the wind, while the aircraft is on the ground. (C. H. C.)

AIR PORT: see AERODROME.

AIR-PUMP. This appliance was introduced by James Watt in 1765, when he invented the separate condenser for steam engines, in order to extract a mixture of air, water and vapour from the condenser, so providing the maximum practical vacuum. The air-pump may be built with the engine and its piston is moved to and fro by a rocking lever, or sometimes by an extension of the engine piston-rod through the back cover of the cylinder. A separate drive by engine or motor makes the air-pump an independent unit. An arrangement of valves allows the inrush of air and vapour on the suction stroke, and expulsion through other valves on the return stroke.

A simplified pump has a conical-shaped piston or bucket (fig. 1) which dashes at high speed down on to the water collected below which it drives upwards into the pump barrel above the bucket, which has just uncovered the ring of ports. The water, vapour and air shoot up the barrel and out through the top valve.

Modern pumps move the air independently of the water. The ejector type of air-pump is the most popular. A steam jet extracts the air and vapour from the condenser, which it discharges to the second jet, which finally ejects the air against atmospheric pressure. The ejector may incorporate a small condenser, an arrangement seen in the drawing (fig. 2), consisting of a series

BY COURTESY OF W. H. ALLEN SONS AND CO., LTD., BEDFORD

FIG. 1—THE WORKING PRINCIPLES OF EDWARD'S AIR-PUMP
The function of the pump is to extract the water and air from a condenser. As the piston descends at high speed the water collected below it is driven with force up the curved walls and through the ports. On the rise of the piston the air is forced out through the delivery-valve with a portion of the water

of small tubes through which water from the condenser (termed the "condensate") is pumped. The primary steam jet sucks in air in the direction of the arrow at A, and discharges it along with the operating steam into the first condensing compartment. The secondary jet withdraws the aerated vapour from the first compartment and sends it with its operating steam into the second condensing compartment. The heat remaining in the steam after it has done its work is thus transferred to the condensate, so acting as a feed-water heater to the latter on its way to the boiler. The tyre pump is a familiar example of simple reciprocating

FIG. 2.—DIAGRAM SHOWING OPERATION OF AN EJECTOR AIR-PUMP

The type shown is operated by steam jets. The primary steam jet withdraws air and vapour from the main condenser and discharges to the secondary jet which finally ejects the aerated vapour at about atmospheric pressure. The tubes constitute a small condenser which helps to warm the condensate ready to go back into the boilers

class, though strictly it should be termed an air-compressor. (See also VACUUM PUMP.)

AIR RAIDS. Directly Great Britain came into the World War, the German High Command began to encourage their public with prophecies of the havoc the Zeppelins were about to work in England, but it soon became evident that for airships to fly in daylight over enemy territory was to invite disaster. Hence, although reconnaissances over the North Sea towards England were begun by airships, the first actual attacks were made by aeroplanes.

Raids in 1914-15.—In Dec. 1914 a couple of bombs were dropped in the sea off Dover, and three days later, on Dec. 24, the first German projectile hit English soil. A few half-hearted attacks by aeroplanes and seaplanes, made during 1915, were ineffective, and it was left to the lighter-than-air machines to cause the first serious damage. In the evening of Jan. 19, 1915, two naval airships approached the coast between Yarmouth and Cromer. They separated and dropped bombs on both towns. Four people were killed.

On April 14, Mathy, boldest of all German air commanders, commanding L9, made a considerable tour over the northern counties. On this occasion he was not particularly successful, most of the bombs falling harmlessly in open country, but the following night L9 caused some damage in Suffolk. The next four raids were similar. Capt. Linnarz, very active about this time in command of one of the military airships, succeeded in bringing his ship over London on the night of May 31, 1915. There was on this night only one raider, armed with an inefficient type of bomb, but there were 41 fires while five people were killed and 14 injured.

Further raids in Yorkshire and Kent on June 4 had little result, but two nights later Mathy again attacked the north. He found Hull, and killed 24 people, besides wrecking some 40 houses. Another airship, LZ37, that attempted to raid on the same night, was destroyed by Lt. R. A. J. Warneford, R.N., while returning home near Ghent. The first serious military damage in England was done by a single ship that raided the north on June 15.

A series of nine raids took place in the latter part of 1915. It opened inauspiciously for the Germans, a zeppelin engaged in bombing Dover being hit by a 3-in. gun that had just been mounted there. She struggled across the Channel and was finished off by bombing aeroplanes.

London was reached on four nights during this period. On Sept. 8 Mathy bombed the city deliberately; the damage done amounted to more than £500,000. Mathy also took part in the raid of Oct. 13, when his ship bombed Woolwich. On this occasion the casualties were 33 killed and 77 wounded. Two buildings were destroyed, 20 seriously damaged, and there were 13 fires, the total damage being estimated at £50,250.

Raids of 1916.—The defences could do no better in the early raids of 1916. Nine zeppelins manoeuvred over the midland counties on the last night of January, one getting nearly to Shrewsbury, and 59 people were killed. Out of 16 British aeroplanes that went up in pursuit, 8 crashed on landing. A month later two airships were able to sit over Hull and bomb it from a low height, without any interference from the defence. From this time, however, the defences improved. L15, one of the five ships that attacked on March 31, 1916, was hit by the gun at Purfleet; it was then attacked in the air by Lt. A. de B. Brandon, of the Royal Flying Corps, eventually falling into the sea off the coast of Essex. Fifteen airship flights were made over England and Scotland during this April. The British losses were 84 killed.

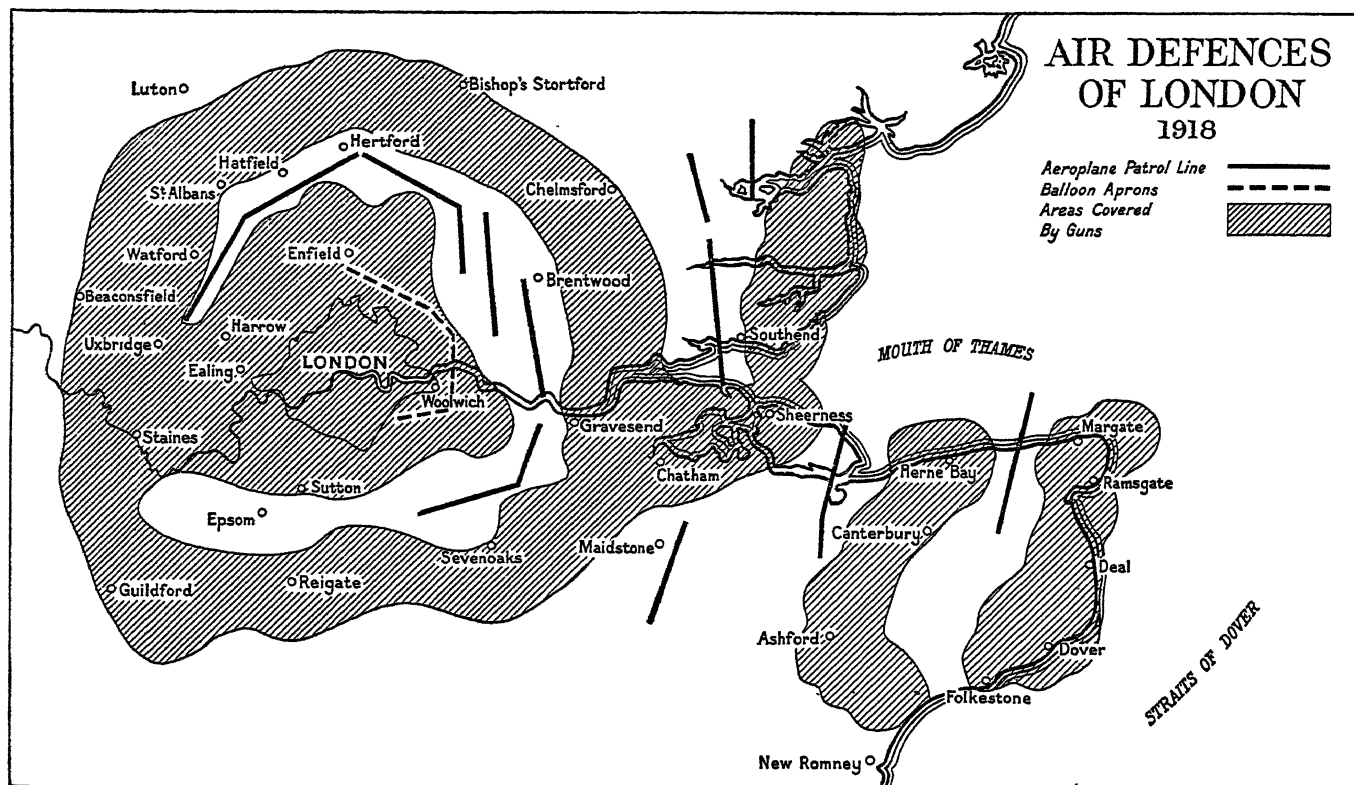

Further raids at the end of April were organized in conjunction with the naval bombardment of Lowestoft and Yarmouth. A large number of airships took part but the result was small. London was saved from bombing by its defences on April 25. One zeppelin was eventually destroyed on the coast of Norway.

An abortive raid on Harwich was followed on Aug. 24 by an attack on London by Mathy. A determined attempt on London was carried out by 14 ships on Sept. 2. The Metropolis was undoubtedly saved by Lt. W. L. Robinson of the R.F.C., who attacked the military airship SL11. She fell, a burning mass, near Cuffley, Middlesex.

On Sept. 23, 1916, 11 airships left Germany and the main attack was directed on London by three of the newest super-zeppelins. Having crossed the Essex coast shortly before 11 P.M., L33 was over east London ten minutes after midnight, and dropped 20 bombs. London, however, was no longer helpless. The searchlights continually lit up the hull of the airship; she was badly holed by the guns, one of her engines was damaged and she began to lose gas and fly clumsily. To add to her miseries, Brandon now brought his machine close up to her. For 20 minutes he stuck to her, pumping bullets into the fabric. As she laboured back towards the North Sea, the crew threw out everything on which they could lay their hands. Her commander crossed the coast at Mersea Island, going out due east. But the certainty that his ship would fall into the sea was too much for him; he turned her about and came to earth near Colchester.

Mathy meanwhile brought his ship L31, in company with L32, up the English Channel and, turning in over the Kent coast, passed straight over the centre of London. South London and the extreme north of the Metropolis suffered severely; but, for some reason, Mathy threw no bombs in the central districts. The handling of the companion ship, L32, was not of nearly so bold a character. Her commander spent an hour circling about Romney marshes. As he crossed the Thames near Dartford he was picked up by lights and attacked by guns. Lt. Frederick Sowrey succeeded in setting the ship on fire in several places; she fell at Billericay. The British casualties on this night were 40 killed.

On the night of Sept. 25, seven ships raided the north. Mathy, on this occasion, took his ship on an entirely new line; he flew up the Channel as far as the Isle of Wight, where he turned north

AFTER THE GERMANS HAD RAIDED LONDON WITH SOME SUCCESS IN THE SUMMER OF 1917, THE AIR DEFENCES WERE COMPLETELY REORGANIZED UNDER ONE COMMAND. PATROLS OF FIGHTER AEROPLANES WERE DOVETAILED INTO THE GUN DEFENCES. A SYSTEM OF BALLOON APRONS NEAR LONDON HAD A CONSIDERABLE MORAL EFFECT AND LIMITED THE HEIGHTS AT WHICH BOMBERS WERE TO BE EXPECTED

and went over Portsmouth. He dropped no bombs on the fortress or dockyard.

Yet another serious attempt to bomb London was made on the night of Oct. 1. Eleven ships started from Germany. Mathy, in L31, came in over Lowestoft about 8 P.M. and as usual steered an excellent course on London. Soon after passing Chelmsford, however, he found that the outer defences on that side of the capital were ready for him. He therefore turned and steered north-east. Turning again, he flew south-west, in order to get into position for his favourite dash down wind over the city. After drifting a few moments toward Ware, he set his engines going and started for north London at full speed. Suddenly a heavy gunfire was opened on him and he decided to abandon his attempt. Sec.-Lt. W. J. Tempest came up to the ship at 12,700ft. and brought her down in flames at Potter's Bar. During the whole of this great raid the only British loss was one man killed. The defence of London had now definitely got the better of the lighter-than-air attack; after this period no German airship ever flew intentionally over the Metropolis.

Deterred by the victory of the London defences, the Germans turned their attention to the north for the final effort of 1916. They met with no better success. Of the ten ships that left Germany in the course of Nov. 27, eight came over land. One was destroyed on the coast near Hartlepool before midnight by Capt. J. V. Pyott of the R.F.C. Another raider, L21, after a remarkable journey right across England to Cheshire, was caught in the early morning, when she was leaving the coast at Yarmouth. She fell into the sea from 8,000ft. and sank at once. During 1916, 18 raids were made on England by aeroplanes and seaplanes.

The first aeroplane attack on London itself was made on Nov. 28, 1916, by a single machine; the only intimation was the fall of six small bombs between Brompton road and Victoria station.

Raids of 1917.—Before the end of 1916 it had become evident to the German command that, if effective bombing was to be kept up on targets that were worth attacking, it would be necessary to try new methods. Early in 1917, therefore, they began equipping a squadron with machines for bombing England systematically.

The first attempt came on May 25, 1917. The 3rd bombing squadron, 16 machines strong, left Belgium early in the afternoon and made the coast about 5 P.M. There were thick banks of cloud over Essex. The task of navigating to London was found too difficult and the leader had to give up the attempt. He therefore turned south. Bombs were dropped on the Canadian camp at Shorncliffe, where there were 100 casualties. The worst effect was produced in Folkestone itself. One bomb fell in a crowded street and killed 33 people, mostly women. The second unsuccessful attempt was made on June 5; 18 machines bombed Sheerness with some effect. The guns at Sheerness succeeded in hitting one of the raiders, which fell into the river off Banton's Point.

London Seriously Damaged.—The third attempt on London was more successful. The whole of the 3rd squadron started in the morning of June 13; London was reached a little before noon. A few bombs were dropped in the East End and near the Royal Albert docks; then, at a signal from the leader, the formation loosed 72 bombs over a small area having Liverpool street station as its centre. The station itself was hit by three bombs. The casualties were severe, 104 killed and 423 injured.

The next raid on London on July 7 was also successful. Twenty-four machines started. The main body of 22 machines came to London. The city received 76 bombs, one of them starting a fire in the General Post Office; 46 persons were killed and 123 injured; 22 buildings were destroyed, and 87 seriously damaged, the total damage being estimated at over £200,000. The anti-aircraft guns produced no effect.

The failure of the defensive arrangements caused considerable agitation, and the British Government ordered a complete reorganization. The London air defences were formed as a separate command to include all the means of defence, both from the ground and in the air. Gen. E. B. Ashmore was brought from France to take charge of the new arrangements.

The new arrangements were soon tested; on Aug. 12 a party of nine gothas made the land near Harwich. After following the coast to the Blackwater, they turned inland for London. The communication system of the defence control worked well, and

the squadrons immediately defending London were at the required height in time to meet the enemy formation. The German commander turned his formation about before reaching the outer line of guns. A number of bombs were unloaded on Southend as the enemy made off, and 32 people were killed. An attempt on Aug. 18 was frustrated by bad weather.

An abortive attack on the midlands by eight airships on the night of Aug. 21 was followed by the last day attack on England on Aug. 22, when Capt. Kleine, commander of the 3rd squadron, started out with 13 gothas to bomb Sheerness and Dover. A number of naval machines turned the Sheerness bombers from their objective, and the German formation, harassed by the British pilots, wheeled south by Ramsgate. Here the anti-aircraft guns, working with great accuracy, shot down two of the raiders. A third was shot down off Dover.

Night Attacks Begin.—The first group of night attacks came in the beginning of Sept. 1917 and one of these reached London itself. On the night of Sept. 3-4, about 10.30, hostile aeroplanes were reported near the North Foreland, and warnings were sent out by the central control a few minutes later when it was clear that they were coming up the Thames. Unfortunately there was serious telephone delay in getting the warning out at Chatham, and before cover could be taken a bomb had fallen on a drill hall in which a large number of naval ratings were asleep. No fewer than 107 were killed and 86 wounded.

Although on this night the defence was ineffective certain points gave hope for the future. Three pilots went up in fast scout machines, and found that it was by no means impossible to handle them at night. The idea also was evolved of barrage fire, a curtain of bursting shell put up in the path of the raiders.

The last raid of this moon period, on Sept. 4, reached London. The barrage fire, organized since the previous night, turned back some of the pilots, but ten raiders reached the metropolitan area. Considering the magnitude of the raid, the damage caused was small, and the total casualties for the night included only 14 killed and 48 injured.

Favourable weather produced a sustained series of raids, opening on the night of Sept. 24, with an attack on London by aeroplanes, in conjunction with an airship raid on Hull and the north. Nine at least of the pilots attempted to attack London itself, but considerable improvement had by this time been effected in putting up barrage fire, which was successful in turning back all but three of the attackers. Although 27 English machines went up they failed to find any of the enemy; the gunfire brought down one of the gothas, which fell in the river near Sheerness.

The attack on the north was carried out by ten airships under Capt. Peter Strasser. Although Hull was found, the raid had very little success. On the following night, Sept. 25, ten aeroplanes

attacked, and nine people were killed. The attacks were continued on the 28th, when some 20 machines came over; the night was cloudy and a few only approached London; they were all kept off by the barrage fire.

The barrage was again effective on the following night, Sept. 29. Out of the 18 or 19 machines that came over only four penetrated far enough to bomb London. The Dover guns did well, bringing one of the enemy down in flames. On the next night, Sept. 30, five German pilots got over London and bombed places as far apart as Highgate, Edmonton and Woolwich; 14 people were injured and two killed. The last raid of the series, on Oct. 1, was made by about 18 machines.

During these raids a large proportion of the attackers had been turned before reaching their target, but the defences were still far from complete. The barrage fire was expensive in ammunition and there was a doubt if the supply could be kept up. The defending squadrons had not reached the necessary efficiency in machines or pilots.

The "aprons," a new defence devised after the raid of Sept. 5, were only beginning to be installed. The central control as organized in Sept. 1917 could give no information to pilots when once they had been sent on their patrols, but schemes to rectify this had already been initiated.

The airship raid of the night Oct. 19-20, 1917, which became known in London as the "silent raid," has points of special interest. Eleven airships met on the evening of the 19th off the Yorkshire coast for an attack on the industrial centres of the midlands. While over England, the ships flew well over 16,000ft. At this altitude the efficiency of the crews was much impaired by height sickness and the intense cold. Another and fatal condition was produced by the weather. Near the ground the air was misty and there was very little wind, but at the height of the airships a strong gale was blowing from the north, and in this the zeppelins drifted blindly south. One airship passed over London without recognizing it and dropped a few explosive bombs; one of 5000 lb. fell in Piccadilly near the circus and caused some casualties.

Realizing that, on account of the ground mists, searchlights would have no chance of lighting up a high zeppelin, the defence ordered them to remain covered unless an airship could be heard. London was saved from a combined attack and the raid ended in disaster to the attackers. One airship only returned to Germany in the usual way; six got back after flying over Holland or across the Allied lines. The remaining four were destroyed during the following day on French territory.

Aeroplane raiding was resumed during the moon period at the end of October. An attempt on the 31st was carried out by 24 machines. Considering that a good many of them got over

London, the effect of the bombs was small, eight persons being killed and 21 injured.

The weather in Dec. 1917 was unfavourable and only three attempts were made on London. The defences showed steady improvement. Two gothas were brought down by anti-aircraft gunfire during a raid in the early morning of Dec. 6. On the night of the 18th one gotha was so damaged that it fell into the sea off Folkestone and was destroyed. On this night the new giant aeroplane dropped one 300kgm. bomb near Eaton square, making a large crater but doing little serious damage. The whole raid, however, cost London more than £225,000, 42 buildings being seriously damaged and nine destroyed, while there were 13 fires. On Dec. 22 the last raid of the year was frustrated by unfavourable weather; one gotha was forced by engine trouble to descend near Margate, where it was destroyed by the crew.

Raids of 1918.—In the five aeroplane raids of the first quarter of 1918 there was a tendency to replace the smaller gotha machines by the new giants. A gotha was destroyed by a defending aeroplane on Jan. 28. During this raid a bomb dropped by a giant fell on a building in Long Acre that was being used as an air-raid shelter, and 41 people were killed. Three giants attacked on Feb. 16; the only one that penetrated to London demolished a house in Chelsea hospital with a 300kgm. bomb. The raid of March 7, 1918, was remarkable as being the only occasion on which aeroplanes attacked London in the absence of any moonlight. Warrington crescent was terribly wrecked.

To turn to the airships, raiding was not resumed until the nights of March 12 and 13, 1918. Both these raids were made at an immense height, and the damage did not amount to much. Five airships of the newest and largest type attacked the midlands on the night of April 12. The end of the airship raiding came on Aug. 5-6, 1918. Five ships came up to the coast of Norfolk, no bombs were dropped on land, but L70, the latest word in airship construction, was destroyed.

In the great aeroplane raid of May 19, 1918, the Germans made their maximum effort in this form of attack; between 30 and 40 gothas of the 3rd bombing squadron took part, with at least two giant machines. Thirteen of the raiders managed to get over London. The casualties included 34 killed and 98 injured and £130,000 worth of damage was done in the London area alone. But the defence had by now made very real progress. The Germans lost seven machines, three shot down in air combat, three destroyed by gunfire, and one from engine failure. This success of the defence was final, and the London area was saved from further bombing.

In addition to casualties (1,413 killed, 3,407 injured) and damage, the German raids on England produced actual results by no means negligible. A night raid stopped munition work over a large area. In order to establish a defence, men and material were kept back from France. Two hundred aeroplanes of the best performance and 200 highly trained pilots were available about London at a time when they would have been of the utmost value on the western front.

European Air Raids.—Apart from raids that formed part of the ordinary operations on the various battle fronts, there were raids on towns of France, Germany and elsewhere, similar in intention to those on Great Britain. On Sept. 27, 1914, the first bombs were dropped on Paris by a German aeroplane. On March 18, 1915, bombs were dropped on Calais, killing 7 French refugees and injuring twelve. On Sept. 22, 1915, French aeroplanes dropped bombs on Stuttgart as a reprisal for the bombardment of open towns by the Germans. In December there were air raids on Calais, and Salonika was bombed by the Germans.

In 1916, on Jan. 29, a zeppelin flew over Paris, dropping bombs which killed and wounded over 50 persons. In Feb. and March 1917 the Germans raided Salonika, and in April 1917 a large squadron of British and French aeroplanes bombarded Freiburg as a reprisal for attacks on British hospital ships. During the autumn of 1917 the British and French repeatedly carried out raids on the towns of western Germany, and in particular on Saarbrücken and Kaiserslautern. On Dec. 24, 1917, a British squadron dropped a ton of bombs on Mannheim-on-the-Rhine.

Early in 1918 the British and French flying corps carried out raids against the towns of western Germany. One of the most successful of these was on Jan. 14 by the British upon Karlsruhe, when the main railway station was heavily bombarded and many buildings set on fire. On March 11, 1918, hostile aeroplanes raided Paris. On March 29, 1918 (Good Friday), a shell from "Big Bertha" hit the church of St. Gervais, killing and injuring many of the worshippers. In May of the same year British airmen dropped 33 bombs on Cologne in daylight and also bombed the port of Durazzo in Albania and sank an Austrian torpedo boat. On July 19, 1918, British seaplanes bombed the Zeppelin sheds at Tondern (Schleswig) and did much damage. (E. B. A.)

AIR ROUTES. A route between any two air ports which offers the best navigational conditions does not always follow a straight line, since it is sometimes necessary to deviate in order to avoid mountainous country or unfavourable weather conditions. In long distance flying, prevailing winds have an important influence in the choice of route, especially for airships. It is well-known that the early sailing ships plying between Spain and America made use of the prevailing trade winds by going out on a southerly course and by taking a more northerly course on the return journey. So when the route to Canada is flown, probably the most advantageous outward course will be via the Azores, while the return journey—during the summer months at least—will be in a direct line to London, as in this higher latitude the wind drift is in an easterly direction.

An aeroplane route organization consists of (i.) terminal aerodromes equipped with accommodation for the aircraft and operational organization, (ii.) intermediary aerodromes at intervals depending on the nature of the route, and (iii.) the necessary meteorological and wireless services and lighting equipment.

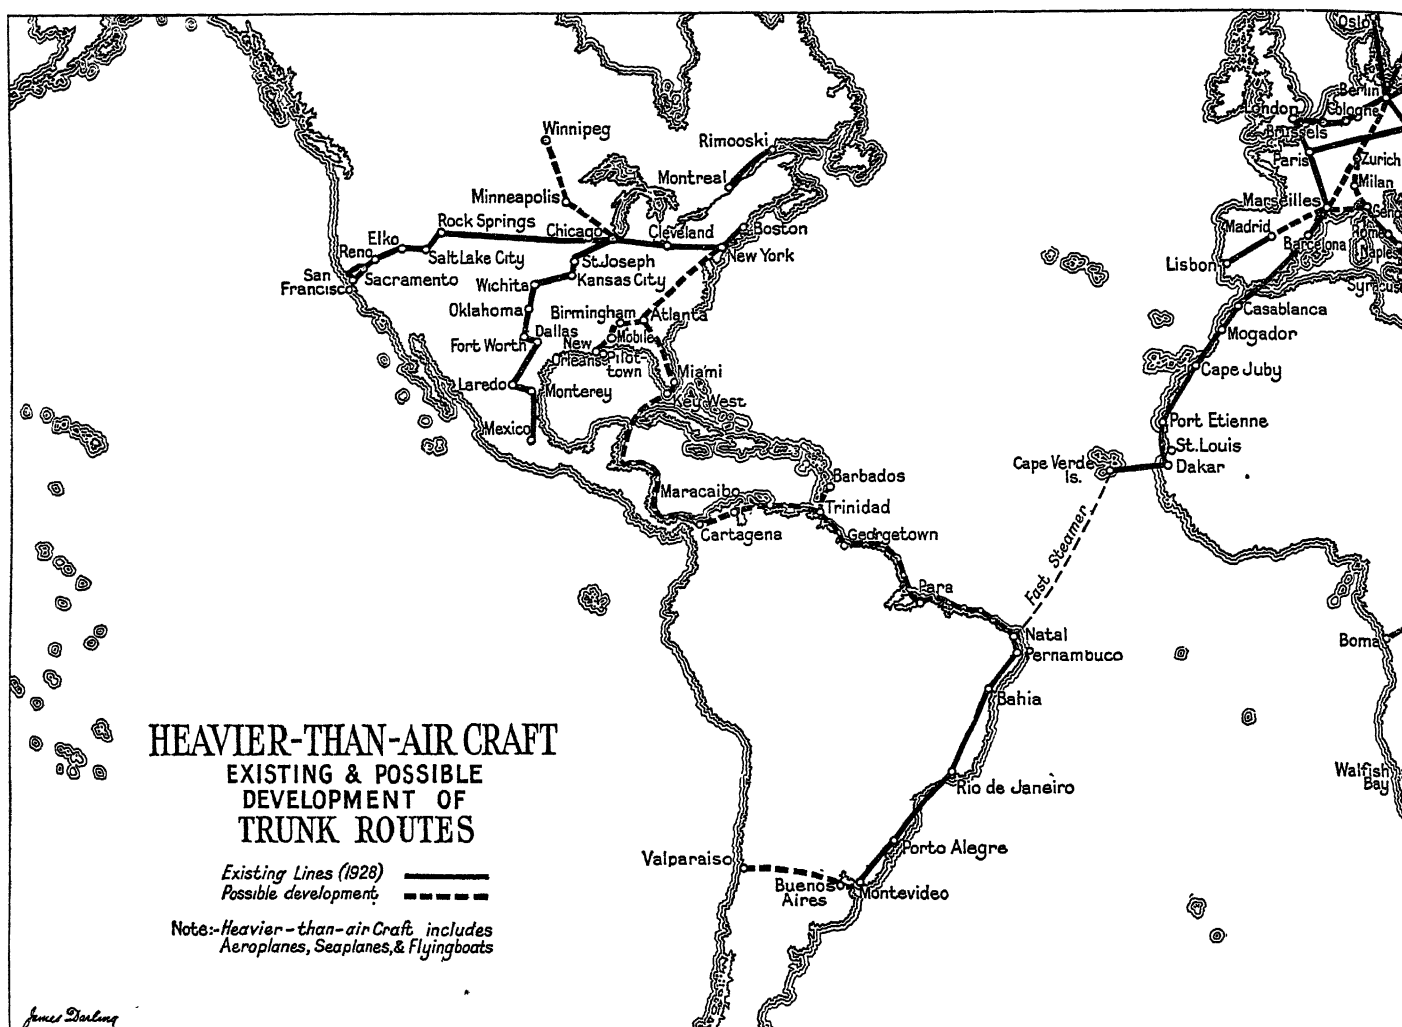

Flight Over an Air Route.—In flight over an organized air route certain simple rules must be observed. The most frequently flown route in the world is that across the Channel from England to the Continent. Brief details of the organization of this route are here given.

Before leaving Croydon the pilot acquaints himself with the weather reports which are exchanged between the principal aerodromes every hour. Permission to take off is signalled to the pilot and when his machine is clear of the aerodrome he is required to report by wireless the passing of certain fixed points on the route. If he decided to fly along a route that has been officially "recognized," he must keep well to the right of the line in order to avoid collision, and if he decides to cross such a line he must fly at right-angles to it and as high as is practicable.

On passing over Lympne, Ostend or Flushing the pilot sees signals which indicate the meteorological conditions ahead. Machines which are equipped with wireless can be warned of bad weather or the proximity of other machines. The wireless stations are provided with direction finders. If a pilot is uncertain of his whereabouts, he can be informed accurately of his position within two minutes. A continuous watch on the safety of the route is kept by a control officer at Croydon, who charts the progress of each machine.

Great Britain.—British air routes to the nearer European capitals have been operated since 1919. A policy for the creation of British imperial air routes is in preparation. Shipping has apparently reached the economic limit of speed, and aircraft alone can supply the more rapid travel facilities that are demanded. It is recognized that commercial development and political unity within the empire are both dependent upon more rapid facilities for personal travel. Aircraft are also well suited to the work of opening up territory before the construction of a railway, and a number of air routes of this kind are already working or being developed, particularly in Australia.

France.—In 1927 French air routes covered 8,304m. and gave rapid communication on the one hand with Prague, Vienna, Belgrade, Bucharest and Constantinople, and, on the other, with Casablanca (Morocco) and Dakar (Senegal). Shorter lines run

also to London, Brussels, Amsterdam and Berlin. The line to North Africa is to be extended to South America via the Cape Verde islands and Fernando-Noronha. At the commencement fast steamers will be employed on the Transatlantic stage, but these will be replaced by large seaplanes. The distance to Buenos Aires is approximately 8,000m., and it will be covered in the early stages in eight days as against three weeks by ship. Eventually the time will be reduced to four to five days. A seaplane line to Syria across the Mediterranean is also in course of organization.

Germany.—The German air system consists of trunk routes and a network of internal lines, about 14,000 route miles in all. Among the most important routes are: (1) Berlin-London; (2) Berlin-Moscow; (3) Berlin-Barcelona (extension to Seville by a Spanish company); (4) Berlin-Stockholm (and Copenhagen-Oslo); (5) Copenhagen-Berlin-Prague-Vienna.

Night flying via Berlin has brought London within 34 hrs. of Moscow, a saving of 38 hours. Eventually this route will extend from London across Europe and Asiatic Russia to China. The route from Berlin to Seville will feed a proposed Spain-South American airship service. The possibility is being considered of running a seaplane service down the west coast of Africa to the Cape.

Belgium.—The Belgian Government has devoted most of its effort to the Belgian Congo. An air line connects Boma on the coast with Elisabethville in the Katanga, a distance of 1,400 miles. A further 1,600m. of air routes are being organized.

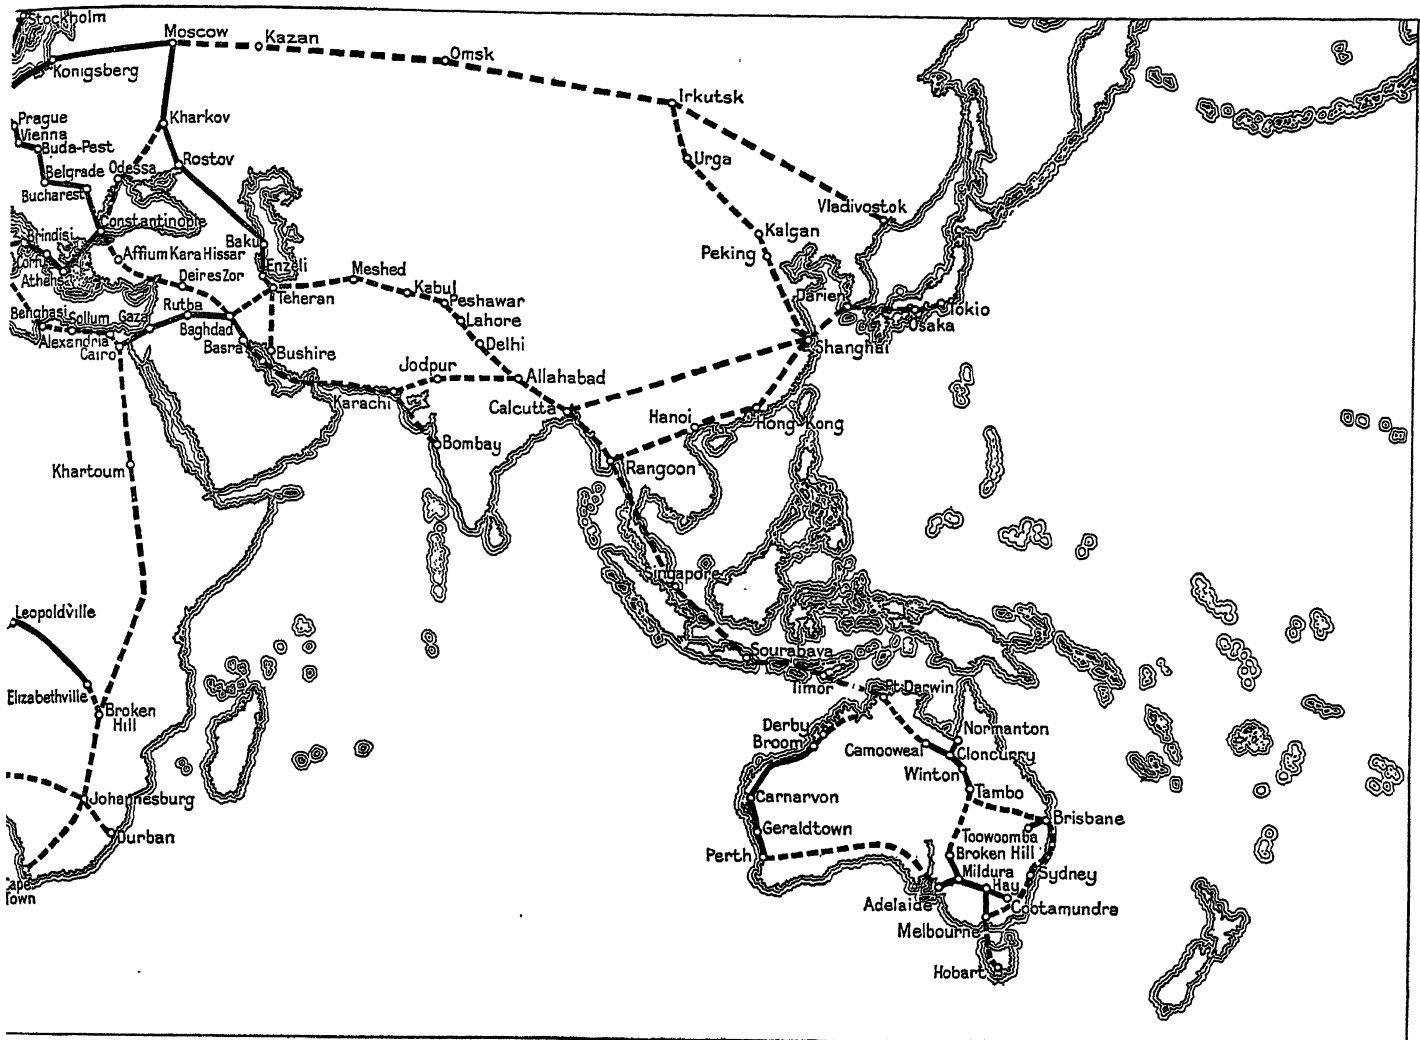

Holland.—Holland operates 1,330m. of air routes in Europe and is now effecting communication with her colonies. In 1927 a flight was made from Amsterdam to Batavia and back in 25 days actual flying time. The regular mail steamer takes 33 days on the outward journey alone. A plan is now being prepared that

contemplates linking up Batavia with Singapore and Australia.

The United States.—The United States has been chiefly concerned with improving her internal communications. An air mail service from New York to San Francisco (2,660m.) was inaugurated in 1920 by the Post Office. By the introduction of night flying in 1924, letters were carried from coast to coast in 32 hours as against three days by the fastest train. By Jan. 1, 1928, 26 contracts had been placed with private contractors, 18 lines were in operation, and the total route mileage flown regularly was 8,441, of which 5,500 had been illuminated for night flying. The total air mail mileage on March 1, 1928, was 11,712. The total distance flown on air mail routes alone in the first six months of 1927 was 2,642,364 miles. The New York-San Francisco route has been entirely transferred to contractors, and the Post Office operating organization has been dispersed. A map of the air routes of the United States appears in AVIATION, CIVIL.

British Empire Routes.—The first empire aeroplane route is that from Cairo to Basra, 1,135m., which is flown weekly and carries a large portion of the mails to and from Iraq. An extension of this line to Karachi, India, has been provided for, and extensions to Bombay and Calcutta are being considered. Later, the route will extend beyond Calcutta to Rangoon, Singapore, the Netherlands East Indies and Australia. In Australia three routes have been established, one from Perth to Derby (1,467m.); a second connecting Charleville, Cloncurry and Camooweal in Queensland, with a branch to Normanton on the Gulf of Carpentaria (1,045m.); and a third from Adelaide to Cootamundra, with branches to Broken Hill and Melbourne (1,000m.). The Australian Government has decided upon a mail service flying by day and night from Perth to Adelaide.

Various flights from Cairo to the Cape have been successfully

made and in the East African colonies an experimental air line from Khartoum to Kisumu (1,400m.) exists. Another centre of activity for aircraft is in the West Indies; and in British Guiana, a journey to the mines that takes nearly three weeks via the Mazaruni river is flown in 2½ hours.

Airship Routes.—At the Imperial Conference in the autumn of 1926, it was made clear that, before airships could operate over any route, meteorological investigations must be carried out and bases provided. Canada decided to construct a base at Montreal; South Africa to provide one at Durban; and Australia one at Melbourne or Perth, or at both places, as soon as the first experimental flights have been successfully made. Prior to 1927, the British Government had decided to erect bases suitable for a series of experimental flights to India. Karachi was selected as the Indian base and has been equipped with a shed and mooring mast, whilst an intermediary landing place was established at Ismailia, Egypt, where a mooring mast has been constructed.

Six airship routes have been selected, including the one to India. These are as follow:—

Route	Bases
(a) England-Egypt-India.	Ismailia (Egypt), Karachi.
(b) England-Egypt-South Africa.	Ismailia, Mombasa, Durban.
(c) England-South Africa, via West Africa.	Bathurst, Cape Town.
(d) England-Australia, via India.	As in (a), together with Colombo, Perth, Melbourne.
(e) England-Australia, via South Africa.	As in (b) or (c), together with Perth, Melbourne.
(f) England-Canada.	Montreal.

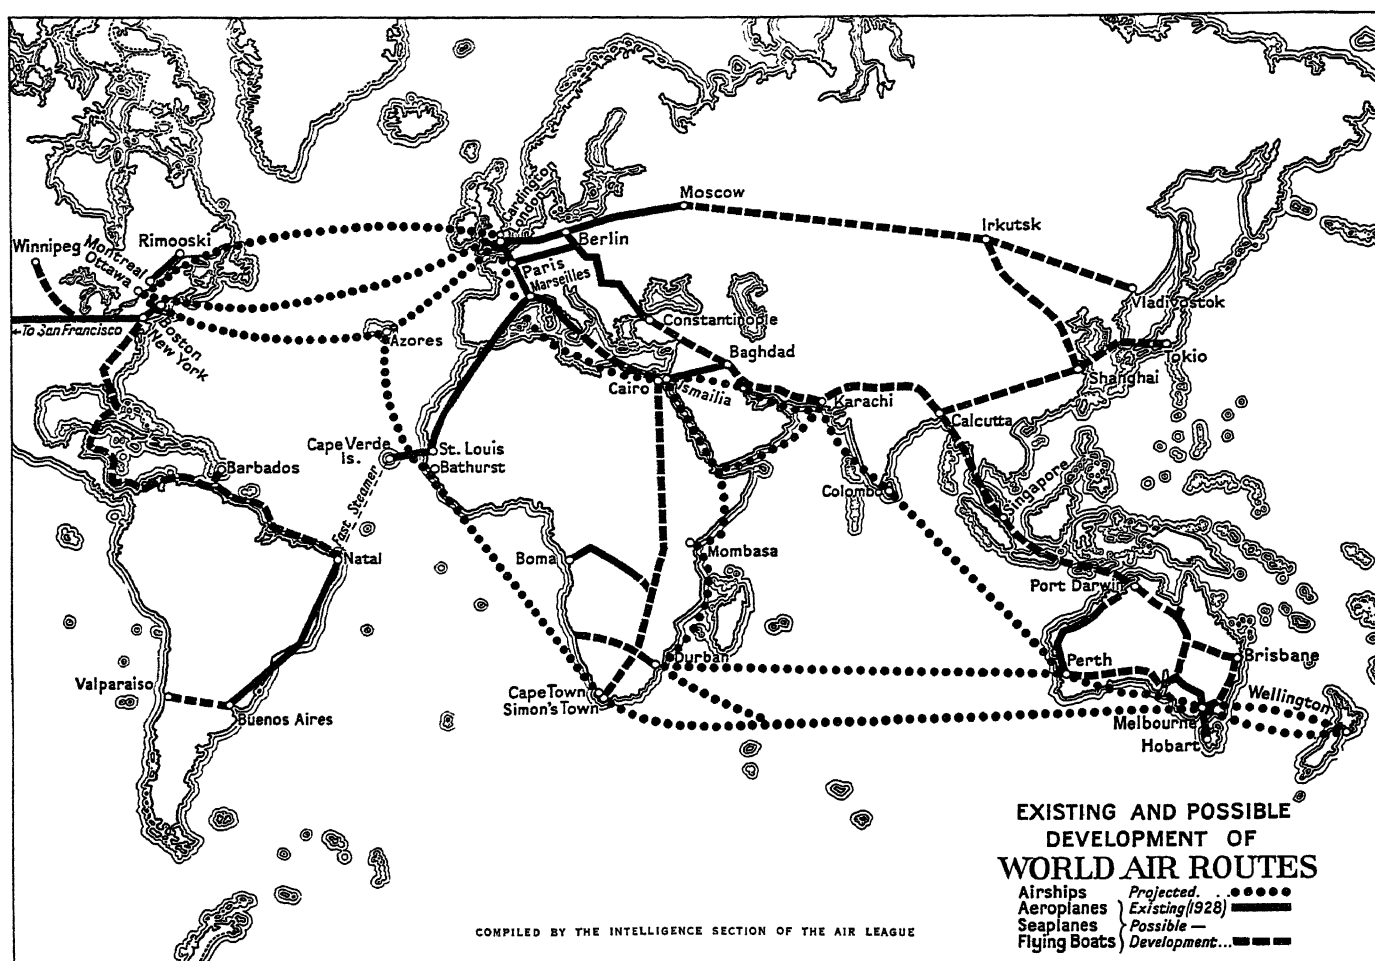

An estimate (in accompanying table) has been made of the saving of time based on a speed over the ground of 50m. an hour.

Route.	Steamship times.	Airship times.	Saving.
	Days.	Days.	Days.
England-Egypt . . .	6	2½	3½
On to Bombay . . .	15	5	10
On to Perth . . .	28	11	17
England-South Africa			
Via W. A.	20	6½	13½
Via E. A.	6	..
On to Australia	10½	..
Australia-New Zealand .	6	1½	4½
England-Canada . . .	6	2½	3½

Via England	24	9	15
Australia-Canada			
Via South Africa and England	48	15½	32½

The air routes of the world covered in 1928 a distance of about 55,000 m. In Europe the network totalled 36,000m. in 1927. The control of air routes in the future will be as important as is the control of shipping lines to-day. (See also AVIATION, CIVIL; AERODROMES.) (I. A. E. E.)

AIRSCREW, the designation of all those devices which, when rotated, tend to screw their way forward, sucking the air from in front and throwing it away behind, or which, when placed in a moving stream of air, are themselves rotated. The term covers (1) fans of a certain type, (2) screw propellers working in air, (3) helicopters, (4) windmills, (5) gyroplanes.

(1) If the airscrew is rotated but restrained from forward movement, air is drawn in from the front and thrown back behind, and the airscrew acts purely as a fan.

(2) If the airscrew is not so restrained, the thrust caused by moving the air backwards drives forward the airscrew and the aircraft, or body, to which it is attached. The airscrew is then acting as a propeller. The thrust exerted, and the volume of air moved, have their maximum value when the airscrew is acting purely as a fan. As the airscrew moves forward, the volume of air delivered and the thrust exerted decrease, and at a certain speed become nothing. At this forward speed the distance moved in one complete revolution is known as the "experimental pitch" of the airscrew. The thrust acts approximately in a horizontal direction.

(3) If, however, the airscrew is placed so that it exerts its thrust upwards in an approximately vertical direction, it is then acting as a helicopter.

(4) In the above conditions the airscrew is driven by some engine or motor, but if it is placed freely on a shaft in a wind, or if it is moved forward through the air, it will rotate and some of the energy in the moving air will be transformed into useful work, and transmitted to whatever mechanism is attached to the airscrew. The airscrew is then acting as a windmill. The wind blows approximately in the direction of the airscrew shaft; *i.e.*, at right angles to the plane of rotation.

(5) If the wind blows at a small angle to the plane of rotation, the airscrew will not only be caused to rotate, but in doing so will exert a thrust. It is then acting as a gyroplane. The best known example of this use of the airscrew is the autogiro, invented in Spain by Señor Don Juan de la Cierva. In this case the plane of rotation is approximately horizontal and the thrust approximately vertical.

General Description.—An airscrew consists of a boss or hub with spokes radiating therefrom—like a wheel without a rim. The number of spokes or blades, as they are technically termed, is usually two, though more are used in special circumstances.

In fig. 1 is shown the plan and elevation of a two-bladed air-

screw intended for use as an aircraft propeller. Below them are shown the sections which would appear if the blade were cut through at points A, B, C, etc. The terms used in connection with airscrews are also shown. Note the term "diameter," the distance from the tip of one to the tip of the opposite blade. For aircraft propellers the diameter varies from as little as four to as much as 20 feet. Note also the characteristic shape of the cross sections of the blade. Sections of this shape are called aerofoil sections; their properties will be found described in any standard work on aero-dynamics. The shape of these cross sections has an important influence on the efficiency of the airscrew. It will be noticed that the blades are twisted; the angle is greater at the root than at the tip. This twist is necessitated by the fact that in order to work most efficiently, an aerofoil section must move at a small angle to the relative air flow.

Now any point in the blade has two simple motions: (1) In the direction of rotation, (2) The forward motion at right angles to (1). In fig. 2 these two simple motions are illustrated to scale as AB and AC for a point near the tip of the blade, and in fig. 3 for a point near the root of the blade; AD is the resultant direction and speed of movement. The speed AC of the forward movement is the same for both points, but the speed AB in the direction of rotation is proportional to the distance of the point from the centre. Its value is zero at the centre and a maximum at the tip.

Thus as will be seen from figs. 2 and 3, the resultant direction of movement of the point near the tip is at a smaller angle to the plane of rotation than that of the point near the centre. Since the aerofoil section must be placed at a small angle to its direction of movement, the blade has a smaller angle at the tip than near the centre. The distance travelled in one complete revolution, when the direction of the resultant motion is along the line joining the leading and trailing edge of the section (*see* fig. 1, section DD), is the geometrical pitch. It has approximately the same value for all parts of the blade, and is usually referred to by the word "pitch."

FROM WATTS, "SCREW PROPELLERS FOR AIRCRAFT," BY PERMISSION OF LONGMANS GREEN & CO., LTD.

FIG. 1.—PLAN, ELEVATION AND CROSS-SECTIONS OF A TWO-BLADED PROPELLER. THE CROSS-SECTIONS IN LOWER HALF OF ILLUSTRATION WERE MADE AT THE POINTS A, B, C, D, E, F, ON THE TOP FIGURE; THEY SHOW THE TWISTED SHAPE OF THE AIRSCREW BLADE

Problems of Design.—The main difference between various airscrews is in the diameter and pitch, and it is the designer's object to choose these for the attainment of certain specified results. He has three aims: (1) To ensure that the airscrew runs at a certain rate of rotation when driven by a certain power, when the aircraft to which it is attached is travelling at a certain speed at a certain height above sea level. (2) To ensure that under these conditions the airscrew will give its maximum efficiency. The efficiency is the ratio of the useful work done by the airscrew to the work done by the engine in turning it. Efficiencies of from 70 to 85% are commonly attained. (3) To ensure that the airscrew is reliable and safe. Airscrews rotate at a high speed. Their tips travel at speeds varying from 700 to as much as 1,200 ft. per second—a velocity exceeding that of sound. This sets up a centrifugal pull in the blade of as much as from 10 to 20 tons, in addition to which the blade must withstand the bending caused by its own thrust.

To satisfy these various requirements, the designer will specify an airscrew of a certain diameter and pitch, with blades of a cer-

height. The design of such an airscrew presents almost insurmountable difficulties, and has not been seriously considered. Although it does not give the greatest efficiency for all conditions, an airscrew of which the pitch only can be varied is a practical compromise. Even this presents difficulties, but experiments are proceeding in most countries, and the problem may be said to be well on the way to solution.

For the ordinary engine the variation of pitch is only required to suit the varying speed of the aircraft. It is true that the power required to drive an airscrew at a certain rate of rotation at a certain aircraft speed varies with the density of the air, which diminishes with the altitude. But the power of the engine also falls off in much the same ratio, hence no great change in pitch or diameter is required for changes in altitude, and the advantage of variable pitch for speed variation alone is extremely limited. But for supercharged engines, which are designed to maintain a constant power at all altitudes, a variable pitch airscrew is desirable.

Materials of Construction.—At first airscrews were invariably constructed of hardwoods, such as walnut or mahogany. The airscrew is built up of a number of superimposed planks or laminae about one inch thick, suitably cut to shape. In the plate the cut planks for a four-bladed airscrew are illustrated. The planks are glued together to form the rough block from which the airscrew is shaped. This and the finished airscrew are also shown.

Wooden airscrews are affected by the humidity and temperature of the atmosphere, and have been found unsuitable for tropical climates. Hence there has arisen a need for metal airscrews. Of such there are two distinct types: airscrews with hollow blades, and those with solid blades. The former are constructed of steel and the latter of a light metal, usually an aluminium or magnesium alloy. Both types have met with a considerable degree of success, but both are heavier and more costly than the wooden airscrew. In large sizes the weight of the solid type appears likely to be excessive, while that of the hollow steel type approaches very closely to that of a wooden airscrew.

AB=Velocity of rotation. AC=Velocity of forward motion. AD=Resultant velocity

tain width and thickness. If any one of these conditions alters—the rate of rotation, the power or the aircraft speed—a different airscrew will be required. Hence the infinite number of designs involved.

Variable Pitch Airscrews.—It will be correctly deduced that since an aircraft can travel at any speed between its lowest and highest speed, and at different heights, it needs for maximum efficiency a different airscrew for each different combination of height and speed. Alternatively it requires an airscrew capable of being varied in pitch and diameter to suit the speed, and the

AIRSHIP, a power-driven aircraft which is sustained in the air through the agency of the lift of a buoyant gas contained in an outer envelope.

To understand the modern airship as it is to-day and to visualize the problems and possibilities of the future one must have some knowledge of the various stages of development from its precursor, the spherical free balloon. The history of this development with all the struggles, the failures and the successes of the pioneers is not only an interesting but also a very human record.

The first known flight made by a lighter-than-air balloon was with one filled, not with gas, but with heated air.

Two French brothers, J. M. and J. E. Montgolfier, were the inventors of this embryo airship. Their family owned a paper mill at Annonay where they experimented with large paper envelopes open at the bottom; under the aperture they burnt more paper; the air inside becoming hotter than the air outside, the envelope rose. Their success so pleased the brothers that they repeated their experiments throughout 1783, each time on a larger scale, until in April they built a balloon with a capacity of 23,000 cu.ft. In June this balloon made a public ascent from Annonay before astounded onlookers, and, indeed, to the intense wonderment of the civilized world.

The Montgolfiers built more balloons, one lifting a load of some 400-500 lb. whilst a third made an ascent at Versailles in the presence of Louis XVI. and Marie Antoinette. It landed its passengers, consisting of a cock, a duck and a sheep, safely two miles away.

The first human ascent was made by J. F. P. de Rozier on Oct. 15, 1783, in a captive balloon; i.e., one attached by a rope to the ground. The King, who, like everyone in Paris, was taking an interest in balloons, would not allow his subjects to risk their lives by rising in a free balloon. He conceded that two convicts should be the first aeronauts, and be pardoned if they came down alive. However, this honour was snatched from them by the enthusiastic young Frenchman, de Rozier, who obtained Louis' permission to make an ascent, taking with him as companion his friend the marquis d'Arlandes.

The Montgolfier balloon for this flight was 74ft. high by 48ft. diameter, having a large opening underneath, below which was slung, by iron chains, a brazier.

On Nov. 21, 1783, at 1.54 P.M., after one false start this historic flight started before a vast crowd in the Bois de Boulogne. The balloon rose to 3,000ft. and remained visible to all Paris for some 20 minutes, landing 1½m. from the point of departure. The fuel used was straw put into the brazier and stirred by the marquis d'Arlandes, who is referred to in contemporary accounts as the "chauffeur." This was literally an epoch-making flight—a flight which opened men's eyes to the fact that there actually existed a new mode of transport.

Invention of J. A. C. Charles.—As with other inventions and discoveries, once the note was struck, progress was very rapid. Only 10 days after the first flight ever recorded, a second one was made by a balloon of a somewhat different type. Professor J. A. C. Charles, a physicist of Paris, realized that the *Montgolfières* rose because hot air was light. He was familiar with hydrogen, which Cavendish had discovered in 1776, and was aware that it was yet lighter. Experiments taught him how easily it

would escape through the pores of paper or linen. Fortunately, the brothers Robert had recently discovered that rubber was soluble, and with a solution of rubber he covered his fabric. Then with hydrogen, laboriously prepared from iron filings and sulphuric acid, he filled his balloon. On Aug. 29, 1783, he released it in drenching rain before an enthusiastic crowd, estimated at 300,000, on the Champs de Mars. It disappeared from sight and eventually came to earth in the country.

All the features of a modern balloon as now used are more or less due to Charles, who invented the valve at the top and suspended the car from a hoop, which was in turn attached to the balloon by netting.

Free ballooning having started with a dash remained for a century not much more than a desultory sport. Few could afford it as a pastime even after the introduction of coal gas by the English balloonist, Green, in 1821. It, therefore, except in time of war, fell into the hands of professional balloonists who gave exhibitions at fairs and entertainments. From time to time attempts were made to organize an industry, but without success. The utter helplessness of the pilot to control its direction prevented the balloon from ever becoming a practical means of transport, and since the place of descent might be the sea, as a speculative amusement it had more than a fair share of danger.

The Modern Airship.—The first steps in the transition to the dirigible balloon were due to Guyot, who, in 1784, proposed to build a balloon with the envelope egg-shaped, the length being greater than the height, and to General Meusnier, who was the first to introduce air bags or ballonets in the outer envelope to preserve the shape as the buoyant gas was lost. It was proposed that these vessels should be propelled by aerial oars worked by hand.

It was not until 60 or 70 years later, in 1851, that the next step was accomplished, when an engineer named Henri Giffard, well known as the inventor of the steam injector, constructed a 5 h.p. steam engine weighing 100 lb., or 20 lb. per h.p., which he used as the motive power for an elongated balloon. Giffard calculated that this engine would give a speed of about 4-5 m.p.h. and such was approximately the result obtained. He constructed several other airships with a certain measure of success, and it is interesting to note that he planned one of 1,970ft. long by 98ft. diameter, with a capacity of 7,800,000 cu.ft. He estimated that the engine would weigh 30 tons and give a speed of 45 m.p.h. The cost was far too great to permit him to carry out this plan.

Among other experimentalists of the second half of the 19th century may be mentioned Charles Renard and Krebs, who created a sensation in 1885 by forming a figure of eight in the air. They drove their airship by means of an electric motor at a speed of about 14 m.p.h. Experiments were also carried out in Germany and Austria.

The year 1898 may be considered the birth year of the modern airship, which the advent of the internal combustion engine, with its more reasonable proportion of weight to horse power, made a practical proposition. A steam engine with its necessary adjuncts of boiler and boiler water was always too heavy, besides which the boiler itself throwing out smouldering sparks was not the best possible companion to an inflammable gas.

This year saw two men of widely different character, with different ends in view, commence a series of interesting trials with airships, one Alberto Santos Dumont, a young Brazilian, in France, the other, in Germany, an elderly German, Count Ferdinand von Zeppelin.

A. Santos Dumont.—Santos Dumont built in all some 14 small airships, and had every sort of accident and adventure. They came down into fields, trees and the sea. He nearly collided with the Eiffel Tower and on one occasion the Paris firemen rescued him from the side of a building. Another time he was making an involuntary descent when he was saved by shouting to some boys to run against the wind with his guide rope. His airships were none of them rigid, and cannot have been very comfortable; for example in "No. 4" he rode on a bicycle saddle. It was with "No. 6" in 1901 that he had his great triumph of winning the Deutsch Prize of 100,000fr. for flying round the

Eiffel Tower and back, a distance of about 7m., in under half an hour. The speed was not high, but it must be remembered they were still early days for motoring. "No. 6" eventually came down into the sea near Monte Carlo.

Count F. von Zeppelin.—Count von Zeppelin, a retired German Army officer, started work in 1898 on the construction of a dirigible which was not only the largest balloon yet built but differed from all previous ships in that it possessed a rigid framework. It was 420ft. long, 38ft. in diameter and had a capacity of 400,000 cu.ft. The framework was of aluminium, which was covered with specially treated linen and silk. The hydrogen was contained in special compartments or gasbags inside. The engines were two 16 h.p. motors, each on a separate car. He also adopted the same idea as Santos Dumont of having a sliding weight with which to raise or lower the nose. On the first trial this caused trouble; the winch working it broke and the framework or hull was deformed. However, the descent was made with fair success except that the airship was damaged by a pile. This was in July 1900. It was repaired, and a second trial flight was made on Oct. 21, 1900, when a speed of nearly 20 m.p.h. was attained.

Zeppelin at first found considerable difficulty in raising funds. However, by 1905, he had collected enough to build an improved model very slightly smaller than "No. 1" but with two 85h.p. motors which were actually lighter than the 16h.p. of the former—the whole airship weighing 9 tons or a ton less than its predecessor. The first trial of this ship was unfortunate, the tow rope fouling a propeller. On landing the airship did damage to itself, which took six weeks to repair, at the end of which time a second trial was commenced. This was not too successful and the airship anchored for the night, when a strong wind so damaged it that Zeppelin had it destroyed. He then started work on "No. 3," an airship which in 1906 justified his faith. German patriotism and enthusiasm were now roused; subscriptions were started and a quarter of a million pounds quickly raised. The Kaiser decorated Count Zeppelin with the Order of the Black Eagle, and shortly afterwards issued orders that "No. 3" should be known as "S.M.S. Zeppelin No. 1."

The LZ 127, named the "Graf Zeppelin" in memory of Count Zeppelin, was constructed at Friedrichshafen, Germany, and made a voyage to the United States in Oct. 1928, covering nearly 6,300m., remaining aloft 112 hours. It was able to navigate around many storm areas but suffered a badly damaged stabilizing fin when over the mid-Atlantic. This ship carried 20 passengers, freight, mail and a crew of 40. The return flight was made over a direct north-Atlantic course in 69 hours.

THE DEVELOPMENT OF AIRSHIPS IN THE 20TH CENTURY

Great Britain cannot be said to have contributed in any degree to the development of airships prior to the World War and the whole history of British airship activity has been one of private individuals urging the Government to stimulate and encourage their development. As a result of persistent advocacy by Mr. Coswell the British War Office was induced to form a balloon department under Captain Templar in 1879. This corps served in Suakin in 1885 and in the Boer War, but it was not until after private individuals, such as Dr. Barton in 1900 and Mr. Willows in 1904, had constructed and demonstrated small non-rigid airships that the War Office were prevailed upon to start work upon a few small airships at the Government balloon factory in 1907. Although, as it will be remembered, Zeppelin had achieved a decided success with his airship "No. 4" by this date, the British Government factory proceeded to construct a succession of small non-rigid vessels of from 21,000 to 77,500ft.—the "Nulli Secundus," "Nulli Secundus No. 2," "Army Airship No. 2," the "Beta" (1910) and the "Gamma" (1912). No novel feature was introduced and the vessels, because of their small size, compared unfavourably with contemporary foreign vessels. In 1910 a French "Lebaudy" and a "Clément Bayard" were added to the Army fleet but neither made a successful flight after delivery.

In the meantime in Germany Count Zeppelin had formed a

commercial company, and between 1910 and 1914 this German Zeppelin company built a succession of rigid airships, which, utilized as commercial vessels, carried, during these years, over 17,000 passengers and flew 100,000 miles without one fatality.

In 1909, British public opinion becoming alarmed at the disparity of achievement between Germany and England induced the Government to take action and the British Admiralty undertook the production of a rigid airship, and a contract was placed with Messrs. Vickers, Ltd. to build "Naval Airship No. 1," subsequently called the "Mayfly."

"The Mayfly."—The design was prepared by Messrs. Vickers, Ltd. in conjunction with Admiral Bacon and other officers.

The following were the principal objects aimed at:—(a) The airship was to fulfil the duties of an aerial scout. (b) She was to be capable of maintaining a speed of 40 knots for, if possible, 24 hours. (c) She was to moor by the nose to a post on the water (or possibly on land also). Floating on the water, she would then swing round always head to wind and be capable, it was hoped, of remaining out in all weathers, and be independent of her shed, except for docking, as in the case of ordinary vessels. (d) She was to carry wireless telegraphy. (e) Sufficient arrangements were to be made for the comfort of her crew to allow of them living in the airship itself without suffering hardship. (f) She should ascend to a height of 1,500ft. or more. (g) The first ship to be purely experimental and as cheap as possible.

These conditions necessitated the ship being of larger size than any hitherto built.

This was the first attempt at the construction of a rigid airship in England, and ended in disaster, happily without loss of life, the ship being destroyed in September 1911 upon emergence from the shed, and before she ever took the air. After this setback airship development was suspended in England until the end of 1913, when an airship section of the Royal Naval Air Service was set up by the Admiralty. This new department placed an order with Messrs. Vickers, Ltd. for a rigid airship of approximately 800,000 cu.ft., the control of the general design being undertaken by the Admiralty and the preparation of the actual drawings and details by the contractors. Construction was commenced in the early part of 1914. After the outbreak of the World War the Admiralty countermanded the order and all work was suspended in March 1915, it being thought that the vessel would not be completed before the war ended. A few months later, the "Zeppelin" bombing attacks induced a further change of policy and not only was the ship proceeded with but orders were given for further vessels. This vessel, the "R.9," was completed in April 1917.

Germany, in the meantime, had forged ahead and by the outbreak of war no less than 30 "Zeppelins" had been built.

An account of "Zeppelin" activities during the war is given elsewhere in the Encyclopædia under "AIR RAMS," and will not be further commented upon except to say that by the end of the war Germany had constructed well over 100 rigid airships.

Non-rigid Airships.—As a result of the Government's vacillating policy in regard to rigid airships, the war found both the British Admiralty and the War Office unprepared in this direction, and in the first few months efforts were concentrated upon the small non-rigid airship for coast patrol and the kite balloon for Army observation work. The first of the small airships, named officially the "S.S." type (Sea Scout) but more popularly called *Blimp*, was completed by Feb. 1915 and in 1916 a more developed type called the "S.S.Z." was produced. These were followed a year later by the "S.S.T." type (Sea Scout Twin) and in each case an increase of size, speed and range was involved. The "S.S.T." had a speed of 50 m.p.h. and could patrol for 50 hours at a stretch.

These vessels were supplemented by larger vessels of the same type, the most notable being the "N.S." (North Sea) type of 360,000 cu.ft. displacement, with a maximum speed of 55 m.p.h. These vessels did remarkably good work and in 1918 there were only nine days in which British airships did not fly, and in that year up to the time of the armistice they had completed over 50,000 flying hours.

Rigid Airships.—To return to the rigid airship programme, the "R.9," with a displacement of 800,000 cu.ft., had a speed of

45 m.p.h. Her useful lift was very small and on that account she had limited endurance, rendering her of little value except for training purposes, although she carried out several patrols in the North Sea. No new feature of importance was embodied and she compared unfavourably with contemporary German vessels.

In 1916, the German "Zeppelin L. 33" was brought down in good condition at Colchester and served as a model from which the "R.33" and "R.34" were built. These vessels, which were not completed until after the war, were a marked improvement on any vessel that had previously been built in England. In 1915, the Admiralty placed contracts for further rigid airships with Messrs. Vickers, Ltd., Messrs. Beardmores and Messrs. Armstrong Whitworth and Co. These vessels were known as the "R.23" class, and were an improvement upon the "R.9" but embodied no really novel feature, and still compared unfavourably with contemporary German vessels.

In 1917, another vessel of 1,250,000 cu.ft. was ordered from Messrs. Vickers, Ltd. This vessel, called the "R.80," was the first rigid airship built in England that embodied any new feature other than those of minor constructional importance. The departure from contemporary practice consisted in building the hull of a good streamline form without any parallel portion. Unfortunately the performance of this vessel was not great, chiefly because of poor engine equipment. Completed in 1920, she compared unfavourably with the German-built "Bodensee," a vessel of approximately the same size, and completed about a year earlier. This latter vessel was used upon a regular service in 1919 between Friedrichshafen and Berlin, and made 103 voyages carrying 2,430 passengers without mishap. The high speed of 81 m.p.h. has been claimed for her.

In August 1918, the design of a new vessel, the "R.38" (2,700,000 cu.ft. capacity), was begun at the Government airship works at Cardington. In Oct. 1919, all airship work was transferred from the Admiralty to the Air Ministry. In 1920, the "R.38" was sold by the British to the American Government. The purchase price was £500,000 and the vessel was to be delivered to the United States by air. The first flight was carried out in June 1921, and revealed defects in rudders, elevators and controls. Further defects were discovered in a second flight a few days later; and a third flight revealed structural weakness in the girders. The fourth flight, Aug. 23, 1921, ended disastrously, the ship breaking into two portions and 44 persons being killed. The loss of life was unduly heavy owing to the fact that both American and British officers and men were on board.

As a result of this disaster the airship department of the Air Ministry was closed down and all airships, airship bases and material turned over to the Disposals Board for sale.

United States.—The history of airship development in the United States is not unlike that of Great Britain. In 1908, the War Department purchased a small 20,000 cu.ft. non-rigid, and in 1911, a 50,000 cu.ft. non-rigid, from the French Zodiac Company. No further development took place until 1916, when, in view of possible intervention in the World War, the Navy Department produced five types of sea scout non-rigids ranging from 18,000 cu.ft. to 84,000 cu.ft., the largest having a maximum speed of 60 m.p.h., and an endurance at moderate speed, of 1,800 m.

About 60 of these vessels were built by the Goodyear Tire Company. After the United States entered the war, British experience of rigid airships was placed at their disposal, and, in 1918, work was started by the United States naval authorities upon the designs of a rigid vessel about the same size as the British "R.33." This vessel, subsequently called the "Shenandoah" (2,148,000 cu.ft.), was completed in 1923, and made her first flight in September of that year. Two developments were made in this vessel, (1) she was designed to be about 30% stronger than contemporary vessels of the same size; and (2) helium was employed as a lifting gas instead of hydrogen. After carrying out a large number of flights and experimental trials at mooring masts the Shenandoah was destroyed in Sept. 1925 on encountering a line squall when over Ohio. The violent vertical gusts generated in this line squall broke the ship into three portions and, unfortunately, the captain and several of the crew were killed. In July 1927, the American Gov-

ernment started negotiations with the Goodyear Zeppelin Company for a new rigid vessel of 6,500,000 cu.ft. at a price reported to be £800,000.

France.—Airship development in France subsequent to Santos Dumont and Zeppelin starting their experiments did not justify the hopes encouraged by that country's early contribution to aeronautics. The Astra Company, the Clément Bayard Company and Lebaudy Frères, all built a succession of non-rigid and semi-rigid vessels, ranging in size from 100,000 cu.ft. to 800,000 cu.ft., for the French and foreign Governments, and one company only, the Zodiac Company, built a rigid airship, the "Spiess," of 575,000 cu.ft. in 1912-13. This vessel had a wooden structure and was unsatisfactory. Since the war, France, with the exception of building two excellent airship sheds upon novel lines, has done nothing in airship development.

Italy and Semi-rigids.—Italy has specialized in semi-rigid airships, and, commencing in 1907, has achieved considerable success in this direction, the Forlanini Company of Milan being prominent in this sphere.

The most notable flight made by a semi-rigid vessel was that of the Italian-built "Norge" in May, 1926, when Captain Amundsen's Arctic expedition started from Kings Bay in Spitsbergen; flew across the Arctic regions, crossing the North Pole; and landed at Teller after having flown 3,000 miles in 71 hours. The "Norge" had previously flown from Italy to Kings Bay by easy stages.

Post-war Developments.—Airship building in Germany, after the World War, was suspended on account of the provisions of the Treaty of Versailles, which prohibited the building of any airship of more than 1,000,000 cu.ft. All German "Zeppelins" were either destroyed or ordered to be delivered to the Allies. The "Bodensee" was taken by Italy as part of that country's reparations, "L.59" and "L.71" by England and other vessels by France. One new vessel only, the "Z.R.3," of 2,400,000 cu.ft., was built by the Zeppelin Company during this period, and delivered to the United States in conformity with the reparation arrangements. This vessel was subsequently re-named the "Los Angeles," and flew from Friedrichshafen to Lakehurst in New Jersey, U.S.A., via the Azores, a distance of 5,000m. in 81 hours, in November 1924, and has since been operated by the United States Navy. The completion of the "Los Angeles" may be said to mark the end of a definite stage in airship development. Up to this time activities in Germany, England and the United States had been mainly confined to producing a vessel that would be useful for war purposes, and with the exception of the "R.80" no new development of a basic character had been attempted. It is true that the British copy of the German "L.33," the "R.34," crossed the North Atlantic and returned successfully in 1919, but even this successful flight did not equal in distance that of the German "L.57" two years earlier, which, in 1917, left Jamboli in Bulgaria, arrived at the Daka Oasis in East Africa, and returned without alighting, having covered a distance of 4,200m. in 96 hours. In each case grave risks were taken during the flight and each was of the nature of a *tour de force* rather than an example of what the existing vessels could be expected consistently to perform.

THE COMMERCIAL AIRSHIP AND ITS PROBLEMS

After the destruction of the "R.38" no new vessel was laid down until 1925, when, as the result of the new policy adopted by the British Government, the Air Ministry was authorised to undertake the early construction of a new airship of 5,000,000 cu.ft. capacity (called the "R.101"), and in October 1924 a contract was placed with the Airship Guarantee Company for a second 5,000,000 cu.ft. ship (called the "R.100").

Instructions were given that both vessels should achieve a speed of 70 m.p.h. and each should have accommodation for 100 passengers. The British and Dominion Governments decided to proceed with the erection of mooring mast bases in Canada, South Africa, Egypt, India and Australia. The Airship Guarantee Company was given a free hand in the design and construction of the "R.100," and the "R.101" was designed by Air Ministry officials.

CONSTRUCTIONAL INTERNAL AND EXTERNAL VIEWS, LOOKING AFT, OF THE AIRSHIP R-100

1. INTERNAL VIEW

2. EXTERNAL VIEW

The hulls of practically all the airships built since the World War are greater in diameter than those constructed before that time. This change is a result of experiments proving that the long narrow cigar shape, characteristic of the lighter-than-air craft first built, is not necessary for the reduction of head resistance. The interior of the hulls is divided into 15 or more compartments containing gas bags. The whole structure is wrapped in an "outer cover" treated with aluminium powder to make it reflect the sun's rays and minimize the absorption of heat. Besides acting as a protection for the gas bags, this covering gives the needed smooth surface to the vessel.

Types of Airship.—As will have been realized from this short history of the airship, the whole tendency of development has been towards larger vessels and higher speeds. Starting as a gas-bag with a motor carried on a small metal framework suspended beneath, the airship has gradually developed into a complicated structure demanding the highest mechanical and engineering knowledge in its design.

In general there have been two distinct parallel lines of development from the free balloon. The non-rigid type of ship is in effect merely an elongated free balloon with car and engine suspended beneath by a suitable arrangement of rigging. In this type of ship the shape is preserved by maintaining the buoyant gas inside the envelope at a definite pressure above the air outside, usually through the agency of air ballonets or bags inside, which, being only partly inflated, are free to expand and in which the air pressure is maintained either by airscoops and valves or by an independent air compressor in the car. The semi-rigid type of ship, often treated as a distinct class, is in reality merely a variation of the non-rigid type. In this, some sort of elongated framework is provided, usually in the form of a stiff keel, carrying the power unit, for the purpose of better distributing the weight of the latter over the length of the envelope. In the rigid type of ship, on the other hand, the shape is maintained by a stiff framework built up of girders over which fabric is stretched to produce the required shape or form and the buoyant gas is carried in independent bags or containers inside. The gas in these gasbags is not maintained at an excess pressure above that of the surrounding air; in fact, the gasbags may not necessarily be fully inflated.

Lifting Power.—All airships obtain their ascensional power by the displacement of air by a lighter gas in exactly the same way that a bladder filled with air and submerged in water will rise to the surface of the water. The magnitude of the "lift" is determined by the kind and purity of the gas, the size of the gas container, and the condition of the atmosphere. Conditions affecting the densities of the atmosphere and any given lifting gas are temperature, pressure and humidity.

At sea level, under normal conditions 1,000 cu.ft. of air weigh approximately 80 lb., 1,000 cu.ft. of pure hydrogen under the same conditions weighs only 5 lb. and 1,000 cu.ft. of pure helium weighs 12 lb. If, therefore, a small balloon is filled with pure hydrogen it will have a "lift" of 80—5 or 75 lb., and with pure helium 80—12 or 68 lb. for each 1,000 cu.ft. of capacity.

In practice, owing to the presence of impurities, the lift of hydrogen in airships is usually about 70 lb. and of helium 60 to 64 lb. per 1,000 cu.ft. Hence in the case of an airship having a total displacement of 5,000,000 cu.ft. the effective buoyancy or lift when filled with hydrogen will be $5,000 \times 70$ lb. or 156 tons, and with helium from 134 to 143 tons only.

These figures give the total lift available and therefore, the hull, engines, fuel, ballast, crew, etc., or "fixed weights" cannot be allowed to total more than this amount. "Disposable" lift is the amount of lift available after all fixed weights have been deducted and is usually given as a percentage of the total lift.

Helium Versus Hydrogen.—Since the United States Government adopted helium in place of hydrogen for the lifting gas of its airships there has been considerable controversy as to the relative merits of the two gases. It is still a matter of opinion which is the more desirable gas to use. British and German experts prefer hydrogen while in America helium is generally used.

The advantage of helium is its non-inflammability, and it is idle to pretend that hydrogen is in any way comparable to it in this respect. On the other hand if the above figures for the 5,000,000 cu.ft. ship are examined and it is assumed that in each case the fixed weights total 110 tons, the disposable lift in the case of the hydrogen-filled ship will be 46 tons, while in the case of the helium ship only from 24 to 33 tons. This represents a very considerable percentage loss in performance, as compared with the same vessel operated upon hydrogen.

Helium is £5 per 1,000 cu.ft. against 5s. for hydrogen, and at present is only obtainable in the United States, although it is reported that it exists in quantity in Canada. (See HELIUM.)

Variation of Volume.—Since the volume of a gas depends upon its pressure and temperature and since with a rise in height the pressure becomes less, it is clear that if the gasbags were full at sea level they would be overflowing at, say, 2,000ft. One of two things must happen in such a case, either the bag must be so strong that the difference in atmospheric pressure between sea level and 2,000ft. can be withstood by the bag or some of the gas must be allowed to escape. In practice it is found undesirable to make gasbags to withstand the difference in pressure due to an alteration of more than about 200ft. in altitude, and accordingly, automatic gas valves have to be fitted to all gasbags. The height at which, with a given amount of gas, the gasbags are just full is known as the "pressure height." An airship can alter its altitude substantially below this height without change of lift, since as the ship descends the surrounding air being denser compresses the gas automatically, but if it exceeds this height it must lose gas, and a new "pressure height" is established. It is clear from this that the higher an airship flies, the less becomes its useful lift, as the gross lift of the gas is less by the amount that has to be allowed to escape through the automatic valves to establish the new "pressure height" at the higher level.

Temperature Variations.—The first flight ever made depended, as has been described, upon the fact that heated air is less dense than cold air. Similarly, heated hydrogen or heated helium is lighter than cold hydrogen or cold helium. Now in an airship it is possible to obtain much the same effect as that noticeable in a glass-house on a sunny day. The sun's rays striking upon the envelope of the ship heat the gas in the gasbags to a higher temperature than that of the surrounding air, with the result that the gas expands and an increased lift is given. This is called superheating. The reverse effect is often found to occur when flying through the clouds.

Height Control.—The control of the flying level of an airship is effected in two ways: for minor alterations of height by the elevators or horizontal rudders and for large alterations by releasing ballast or gas. The action of the elevators is dynamic and can only operate when the ship is moving, and the magnitude of their effect depends upon the speed of the vessel. In the "R.100" at full speed, the "dynamic lift" is estimated to be as much as 17 tons and except for mooring and landing is mainly depended upon to keep a constant height level.

Hull Structure.—The most striking development in the more modern ships as compared with the earlier war-time "Zeppelins" lies in the changes made in the shape of the hull. The early "Zeppelins" had long, narrow, cigar-shaped bodies, the ratio of length to diameter being about 10—1 and embodied a very long parallel portion with a relatively short conical bow and tail. This original shape was adopted partly from the desirability of keeping the diameter as low as possible to meet shed difficulties, partly because it may have seemed that the obvious way to reduce head resistance was to make the ship as long and narrow as possible. Experimental investigations have shown, however, that, providing the hull is correctly streamlined, the head resistance per unit of volume of a hull, having a length-diameter ratio of only 5—1, may be very considerably less than of these old shapes, which were extremely poor aero-dynamically. Again, the vast amount of investigation into the distribution of stresses in the hull framework carried out during and since the war has shown that with the shorter ships it is possible to obtain a strength and factor of safety double that allowed in the older ships for the same proportional weight of structure.

This development is strikingly shown when comparing the "R.33" with the "R.100". The length diameter ratio of the "R.33" is 9—1 and the "R.100" 5.3—1. The "R.100" is truly streamlined and the "R.33" has a long parallel portion. The resistance of the "R.100" shape is only half that of the "R.33" shape per unit volume. Contrast shapes in Pl. II, figs. 1 and 5.

The hull itself consists of a metal framework, divided into 15 or more compartments into each of which a gasbag is placed. The gasbag consists of linen fabric coated with gold-beater skin and made up in the shape of a cylindrical container. Surrounding and containing each gasbag is a network of wires, distributing and

conveying the lift from the bag to the hull structure. The whole structure is then covered with an envelope of fabric called the "outer cover," the function of this outer cover being to give a smooth surface to the vessel, protect the gasbags and, being specially treated with aluminium powder, to reflect the sun's rays and minimize the absorption of heat.

The engines of the ship are usually carried in separate cars or gondolas suspended from the metal framework of the hull, although, in order still further to reduce resistance, proposals are now being made to place the engines inside the envelope.

The fuel tanks are carried inside the hull suitably suspended from the girder work, and the control cars, passenger quarters, etc., are either built into the hull or suspended from it. As can be seen from Pl. II.-2 showing the girder work of the "R.33" and Pl. I.-1 showing that of the "R.100," considerable differences exist in different designs.

There seems little doubt, however, that the enclosure of the passenger quarters entirely within the hull, as developed for the first time in the "R.100" design, will form a precedent that will be universally accepted, owing to the reduction of resistance. It has also been proposed to situate the control car in the extreme bow.

Performance.—If the atmosphere was always calm the performance of an airship would be almost incredible, since the power required to drive her at a given speed varies as the cube of the speed, and consequently at low speeds her range would be immense. Under practical conditions, however, that is not the case as average winds that may be encountered upon any flight range up to 30 m.p.h. Under adverse conditions the winds may be as much as 60 m.p.h. or more. If, therefore, the airship is to be a dependable means of transport her speed must be high as compared to the winds she may encounter, and for practical purposes, especially from the commercial point of view, a cruising speed of less than 75 m.p.h. is not of much value, and in the opinion of those who have studied the problem a cruising speed of 100 m.p.h. will be required before the airship will be able to maintain a regular commercial transport service. For commercial work, an equal division between fuel and paying load gives the maximum ton-miles and determines the distance between stopping and consequently refuelling bases.

Consider the performance of the "R.100" as an example, as she is the first really commercial vessel that has been designed. The useful lift is 73 tons. From this must be subtracted 21 tons for crew, ballast, loss of lift to 2,000 ft., etc., leaving 52 tons for fuel, passengers and freight. Half of this is 26 tons. The consumption of fuel at 75 m.p.h. is half a ton per hour, thus giving a total endurance of 52 hours at 75 m.p.h., or 3,910 m.

To allow for contrary winds fuel for 50% more than the geographical distance must be carried, so the performance of the "R.100" can be said to be 2,600 m. at 75 m.p.h., carrying 26 tons of paying load.

Strength and Factor of Safety.—The development of the airship, unlike that of the aeroplane, was hindered rather than helped by the World War, owing to the much longer period of time involved in producing a new design. The necessity for the rapid increase of the number of airships after the outbreak of war prevented the natural improvement in shape which would otherwise have developed, and furthermore, the height of the sheds or hangars limited an increase of diameter. The result was that both in Germany and England long, parallel-bodied and cigar-shaped ships, having an extremely high head resistance per unit volume were to a certain extent standardized even although their defects were obvious. These vessels, owing to their great length and small effective depth considered as a beam, were subjected to excessive bending moments and stresses when turned rapidly or manoeuvred under gusty atmospheric conditions. In these circumstances, with the small total lift available, it was impossible to provide a really adequate margin of strength and structural failures, as in the case of the "R.38" and "Shenandoah," followed.

In the case of an airship, structure strength has to be provided to meet two distinct sets of conditions; the first, definite and readily calculable, arising from the tendency of the ship to deform

under the pressure action of the buoyant gas in the hull, and secondly, the bending condition arising out of rudder action, gust action, etc., which are known with much less exactitude. In the case of the latter an assumption has to be made as to the character and magnitude of the worst possible condition the ship will have to meet, and an arbitrary condition is used of somewhat similar character to that employed by naval architects in the design of marine vessels. When the magnitude of the worst condition is fixed the distribution of the corresponding stresses throughout the structure can readily be calculated, since the airship structure is an open lattice structure amenable to exact calculation. The factor of safety of the "R.100" is several times as great as that of the older types of ship when calculated under parallel conditions.

Air Currents and Storms.—The airship has to encounter three general types of air-currents. First, the ordinary depression, which may be anything, in temperate zones from 700 to 1,500 m. across. The wind will be steady and blowing in a horizontal direction at speeds varying from a few miles per hour to 30-40 m.p.h. at low altitudes. An airship is not much affected by such a wind in so far as the structure is concerned, and although such a wind would create a rough sea, the air-borne vessel is flying almost as calmly as in still air. The distance the vessel makes good over the ground will, of course, be altered by an amount corresponding to the strength and direction of the wind.

Secondly, there is what is known as a "line squall." This meteorological phenomenon is caused by cold currents meeting and overlapping hot currents of air. These line squalls may be several hundred miles across and generate dangerous vertical currents. These vertical currents will affect the airship in much the same way as the vertical motion of the waves affect a marine vessel. In certain cases the vertical velocity of these gusts is very high and, moreover, being in some cases of small diameter may be likened to a stream of air being discharged from the nozzle of a hose. If an airship strikes one of these vertical gusts when flying at high speed, she will be thrown violently out of her horizontal path and be subjected to severe stresses. It is computed that the vertical gust which destroyed the "Shenandoah" had a velocity not less than 1,400 ft. per minute. The effect of these gusts upon an airship structure was largely neglected in all vessels prior to 1925.

In the "R.100" a factor of safety has been provided to enable the vessel to encounter a vertical gust of no less than 4,000 ft. per minute, and of a diameter of only 800 ft., when encountered at the full speed of the vessel. Experience of the behaviour of airships in "line squalls" is still very limited.

Thunderstorms.—Thirdly, there are the still more violent and intense forms of atmospheric disturbances such as thunderstorms, waterspouts, cyclones and hurricanes. All these have one characteristic in common in that they are of a very local character and usually travel at a slow speed seldom exceeding 20 m.p.h. Every endeavour should be made by an airship commander to avoid disturbances of this character, and hitherto no experience has been obtained as to the behaviour of an airship encountering such disturbances other than thunderstorms. The chief danger in the thunderstorm is the violent vertical and horizontal gusts and electrical discharges such as lightning. There have been a considerable number of cases of rigid airships being struck by lightning, but so far experience has shown that the metallic framework of the ship affords sufficient capacity to absorb the electrical charge, and the water vapour in the exhaust of the engines forms a sufficient conductor for the gradual discharge of the induced current. Lightning is a grave danger to non-rigid and semi-rigid vessels owing to the absence of this metal framework.

Engines.—Up to the present no efficient and satisfactory airship engine has been evolved. The general line of attack in order to avoid the use of petrol, with its attendant dangers, has been to develop a light Diesel engine using heavy oil, or a sleeve-valve engine using hydrogen and kerosene as fuel. In Great Britain one engine of each type was under trial in 1928; the plan being to equip the "R.101" with light Diesel engines if successful. The "R.100" was first fitted with petrol engines, but it was antici-

pated that these would be changed for one of the other types as soon as they could be considered serviceable.

Experiments upon light Diesel engines are being conducted both in Germany and America.

Mooring Masts.—A large airship cannot be moved into or out of its shed or hangar except in a comparative calm, unless the wind is blowing in the line of the length of the shed. In Germany a revolving shed was made, so that, whatever the direction of the wind, the length of the shed could always be made to coincide with the direction of the wind. When it is realized that a modern shed may be 850ft. long, 180ft. wide and 180ft. high, weighing several thousand tons, it is obvious that the engineering problems involved in rotating so vast a structure are so great as to render a simpler and cheaper solution to the problem imperative.

As will be remembered, the specification of the first British rigid, the "Mayfly," in 1909, included a mooring tower or mast. Prior to that vessel's destruction she was moored to a mast and remained safe during winds with gusts up to 48 m.p.h. In 1912 this idea was adapted by the Royal Aircraft Factory at Farnborough to the mooring of a non-rigid vessel. Many of the essential features employed at Farnborough, such as the fixation point being free to rotate about the axis of the mast and the ship being free to rock vertically, have remained in all masts hitherto constructed. Recently the U.S. Government has awarded contracts for short mooring masts which are mounted on caterpillar trucks, and can be used for handling or towing airships on the ground.

Subsequent to 1912, a further set of experiments were carried out at Barrow, a somewhat taller mast with a horseshoe being utilized. In 1919, a prolonged series of trials with the "R.34" were undertaken at Pulham. The ship remained continuously at the mast for 70 days and experienced gusts up to 43 m.p.h.

These experiments were continued in 1921 with the "R.33," various modifications being made both to the mechanical details at the mast-head as well as to the method of operating the vessel.

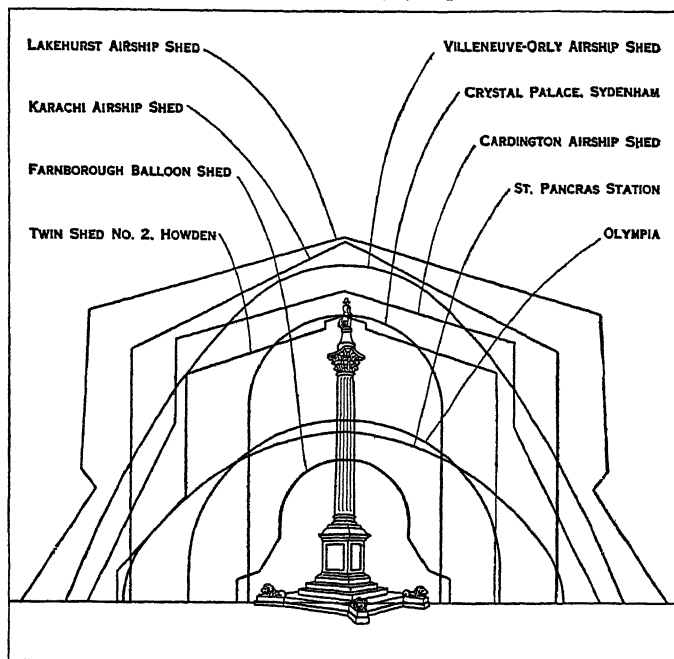

In 1925, the Royal Airship Works at Cardington, in conjunction with the Works Department, designed and erected a mast some 200ft. in height at Cardington for use with the "R.100" and "R.101." Similar masts are either approved or in course of erection in Egypt, Canada, South Africa and Australia. Considerable criticism against the actual type of mast-head and the necessary complementary fittings in the airship itself was levelled against this design by the Airship Guarantee Company in 1925 and 1926, and an alternative system was suggested by that company. The whole question is involved and highly technical and it seems likely that further experience is likely to result in considerable modification to the existing types. The U.S.S. Patoka, an aircraft tender, carries a mooring mast. The breaking away of the "Shenandoah," and the "R.33" from their masts in 1925 indicating the necessity of improvement.

AIRSHIP SHEDS. Airship sheds or hangars are used to accommodate airships during construction, repair or docking. The continuous increase in the cubic capacity of airships has necessitated a corresponding increase in their housing accommodation until the modern hangar ranks amongst the biggest buildings of the world.

When the dirigible was in its infancy such funds as its protagonists commanded were needed for the construction of the ship itself and little could be ear-marked for its shelter; but as the airship emerged from the early experimental stages it became evident that accommodation was an important factor in development. M. Santos Dumont, contemplating with pardonable pride the "first airship station" which was completed in a Paris suburb in 1903, describes its doors. "Tourists" he says "told each other (quite correctly) that doors so great as these had never been before in ancient times or modern." Each of these doors ("sensational features" in 1902) was 50 ft. high, 16½ ft. wide and weighed 4½ tons. The shed itself had sides and roof of canvas, the central stall being 165 ft. long, 31 ft. wide and 44½ ft. high. Seven years later, in 1910, the British War Office built a hangar at Farnborough, Hampshire, 360 feet long with a clear span of 60 ft. and a height inside of 75 ft. A year later the roof was raised 15 ft. to allow space for the Army Airships, Alpha and Beta.

RELATIVE SIZES OF GREAT AIRSHIP SHEDS
In this diagram the height and width of several great airship sheds are compared with well-known London landmarks. The Nelson monument is 142 ft. high. For comparison it may be noted that the Statue of Liberty is 151 ft. 5 in. high.

In 1927 the largest hangar in the world was at Lakehurst, New Jersey, U.S.A. where it was erected in 1910-20. This immense building encloses a gross area of 41,852,360 cubic feet.

In England the largest shed was built for the Admiralty at Howden, Yorkshire, in 1917-18. This is a twin shed (to house two ships) the enclosed volume being about 37,837,500 cubic feet. It covers an area equal to 7.1 acres or including the doors about 8½ acres, a greater superficial area than is occupied by the American shed. The total amount of structural steel absorbed is about 4,600 tons.

The measurements of some of the great hangars of the world are given in table overleaf.

Where situated.	Date of building.	Volume of shed. cu. ft.	Lgth.	Hght. in-side.	Span.	Re-marks.
Nordhotz, Germany	1915	..	664	98	116 each	Twin span shed.
Orly, France	..	34,108,524	984	164	230	..
Howden, Yorks	1917-18	37,837,500	754	140	150 each	Twin span shed.
Cardington Karachi	1925 Com-pleting	27,234,480 33,430,500	812 850	157 170	180 202	..
Lakehurst	1919-20	41,852,360	800	172	258	..

Construction.—Hangars are usually constructed with steel framing covered by galvanized sheets on sides and roofs, the flooring being of concrete. The roof covering of some of the more recent sheds is of corrugated sheeting coated during manufacture with alternate layers of asbestos and bitumen.

A simple framework is usually found advisable, and the three-pin arch or some adaptation thereof is a type that provides as far as possible against temperature stresses or settlement of the foundations.

One of the few examples where reinforced concrete has taken the place of steel is to be found in a remarkable shed built at Orly in France taking the form of a parabolic fixed arch, springing direct from the ground level giving a clear width and height at the doors of 230ft. and 164ft. respectively. The arch ribs form continuous walls in corrugated form, the depth of the corrugation varying from 17ft. at the ground to 10ft. at the crown, the centres of the corrugations being about 24ft. apart longitudinally. (See fig. on p. 473.)

When a wind is blowing other than fore and aft the shed, an airship can only be housed or unhoused with difficulty and risk. Sheds are therefore built with their longitudinal axes in line with the prevailing wind. Further efforts to overcome this difficulty have been made:

- By erecting wind screens from 70ft. to 130ft. high framed in steel and sheeted. No appreciable benefit resulted.
- By anchoring a shed like a floating dock on a sheet of tideless water, where this shed would naturally swing head on to the wind. Such a method was tried by Count Zeppelin on Lake Constance but the disadvantages were found to outweigh the advantages gained and the idea has not been developed.
- By constructing revolving sheds. With the increasing size of the shed required this presents an interesting and very expensive though not unsurmountable problem.

The revolving shed built at Nordhotz therefore merits description. The framework is all steel, the sides and roof have a steel corrugated sheet covering, a portion of the floor being of concrete, the remainder being of timber.

The total revolving load is about 4,000 tons and rests on sixteen four-wheeled bogies, running on a circular rail track of 5ft. 3in. gauge, the diameter being about 475ft. A massive concrete pivot 26ft. in diameter centres the whole structure. The shed itself revolves about this point in an annular pit of 650ft. diameter and 13ft. depth, the floor of the shed being level with the ground surface. Electric motors are fitted to all bogies for turning the shed, the total horse power being about 184.

Sliding or rolling doors have generally been used at both ends of the shed, but in later designs at one end only. Two types have been used, (a) a vertical door, travelling across the end of the shed on bottom wheels on a concrete rail track, the top being supported horizontally on guide girders, either fixed to the shed or supported independently on towers; (b) which is more generally adopted, a door framework rolling on parallel rail tracks, sufficiently far apart to make the door, when suitably ballasted, self-supporting and independent of the shed altogether. This involves moving a much heavier weight when opening and closing, but has proved satisfactory and costs less than type (a).

Doors are usually operated by hand gear. In some cases a cap-

stan, fixed on the door, is used, driving by means of spur gearing direct to the travelling wheels. A more efficient method, however, is a cable or chain, fixed at each end to a ground anchorage and passing over the drum of a winch fixed on the door framework. At Cardington each door consists of four separate leaves, each weighing (including the necessary ballast) about 245 tons. Two leaves coupled together are opened easily in 10 minutes by 6 men. (See AIRSHIPS.) (C. D. B.)

AIR SICKNESS: see ANOXÆMIA.

AIR WARFARE. This article deals with the general principles governing the employment of air forces in war, and with the effect of the advent of air power upon problems of the defence of the British empire. It does not enter into any details either of air fighting (for which see AIRCRAFT IN WAR) or of co-operation with a navy or an army (for which see AIR CO-OPERATION).

Characteristics of Aircraft.—Aircraft move very rapidly and the time during which they have to remain in contact with their objective is very short, merely sufficient for accurate bomb-sighting. It must not be supposed that aircraft attacks are affairs in which the main object is to get away without being caught; they are deliberate actions which are completed quickly owing to the nature of the instrument. Aircraft are not limited to any definite line of advance, but are free to move in any direction and can approach their objective from practically any direction and at any height between say, 100ft. and 20,000ft. This means that the defenders of an area 16 miles square have about 1,000c.u.m. to watch. Or, again, if, as often occurs, there are continuous cloud layers, aircraft patrolling a line have two or more separate fronts to watch, e.g. in the case of two cloud layers, one above the top layer, a second between the two layers and a third below the bottom layer.

With the possible exception of high mountain ranges, aircraft are not stopped by any ordinary obstacle, either natural or artificial. The stretches of sea or lines of fortresses that used to form the frontier defences of nations are barriers no longer. They are not tied down like an army by a line of communication from the fighting front to their base; they can go back to their aerodromes by an entirely different route from that by which they arrived. On the other hand, the time during which they can remain active *i.e.*, in the air, is short, owing to the limitations of their fuel and ammunition capacity; they have no physical stopping power, such as is afforded by barbed wire or bayonets and they are handicapped by certain weather conditions, especially fog and low clouds.

There is a prevalent idea that large aircraft are necessarily more effective fighting instruments than small aircraft, and that there is no inherent difficulty in constructing a battleship of the air. This idea is based upon the assumption that, as regards scalar effect, aircraft follow the same law as ships. This is so in the case of dirigibles, but there is a fundamental difference between ships and aeroplanes. Increasing the dimensions of a ship results in an increase in the ratio of useful load to total weight, hence in the case of warships it is possible, by increasing the total tonnage sufficiently to have a greater ratio available for engines, fuel armour and armament, and thus to get any desired combination of speed, endurance, protection and gun power. Increasing the dimensions of an aeroplane, at any rate with the present methods of construction, will increase the absolute load that can be carried but does not increase the ratio of useful load to total weight; the ratio remains constant or even decreases with increase in size. Speed, rate of climb and handiness are of first importance in air fighting, and these can be obtained to a higher degree in small aeroplanes than in large. The fighting aeroplane of to-day is the comparatively small machine, generally with one occupant—sometimes with two—and not the big heavy weight-carrier.

It has sometimes been said that aircraft are wasteful in man power because it requires a large number of men to keep one aeroplane serviceable at the front. Actually, on the Western front in the war of 1914-18, the numbers were less than those required for a field gun, but in any case the argument is wrong. We do not want to kill off our young men in war; we want to keep them for the peace which is beyond war. By the use of

CONCRETE AND STEEL SHEDS BUILT TO HOUSE MODERN AIRSHIPS

1. Corrugated, reinforced concrete sheds at Orly, France, built in the form of a parabolic arch
2. Twin airship sheds at Howden, Yorkshire, covering approximately eight and one half acres
3. Airship shed. Royal Airship Works, Cardington, Bedfordshire, made of corrugated sheeting in a steel framework
4. Hangar doors at Lakehurst, New Jersey, 177 ft. high, 136 ft. long and 77 ft. deep, operated by electricity and braced by steel, with an approximate weight of 640 tons each

aircraft we are substituting machinery for flesh and blood; instead of exposing one-third of our serving men to steel, lead and gas, we are exposing but one twenty-fifth. Provided we attain our end, the fewer men we expose to risk of wounds and death the better. War machinery of all kinds should not be regarded as wasting a large number of men in maintenance, but as effecting a vast economy in the utilization of available man power.

Means of Winning Wars.—Destruction, moral or physical, of the enemy's army, followed or preceded by invasion of his country, is the most obvious method of forcing a nation to accept its opponent's solution to a matter in dispute, but it is not always easy to achieve, is frequently a lengthy process and always involves a heavy sacrifice of life. Being, however, the normal method by which wars have been won in the past, it is often assumed to be the only method of winning wars in the future. This assumption fails, however, to take into account certain results of the world's progress; it is one method, but by no means the only one and under some conditions, not the most important.

The means which a nation can now utilize in order to bring pressure to bear upon the enemy people, may be grouped roughly as follows:—

- (a) Moral (i) Propaganda; (ii) Dislocation of normal life.
- (b) Economic; Stoppage of movement of goods.
- (c) Physical (i) Deprivation of necessities; (ii) Injury to person or property; (iii) Loss of means of winning the war.

Many of these interact; for instance, stoppage of movement of goods may lead to deprivation of necessities which will in turn render the people more susceptible to moral effect. Again, the same stoppage will mean reduction of trade which may lead to a nation being unable to keep sufficient credits in foreign countries to purchase essential material for munitions. To deprive an enemy nation of the possibility of winning a war, part at any rate of the system by which it carries on that war must be destroyed, viz.:—(1) The centre of government. (2) The navy, army and air forces. (3) Munition factories and transport system. Let us now briefly consider what means each of the three fighting services utilize in order to bring pressure to bear upon the enemy nation.

A navy acts mainly by economic methods, through control of overseas communications; the result of this will not usually become apparent for a considerable time.

An army ultimately brings pressure to bear by occupation of the enemy's country but cannot do this until it has disposed of the enemy's army; as has already been stated, this is usually a slow and costly process both to life and property.

An air force acting separately can contribute its share of pressure in several ways; by dislocation of the normal life of the people, by deprivation of supplies through attacks on transportation systems, by bombing the centre of government. Many of the objectives which an air force can attack at the beginning of a war, could, prior to the advent of aircraft, be reached only after prolonged fighting. This power of bringing direct pressure to bear upon its enemy from the start of the war, may be a deciding factor in reducing the time required to compel an opponent to come to terms.

Separate Action of Air Forces.—When reference is made to an air force acting independently or separately, this does not imply it will carry out a war on its own account without reference to the action of the other services. All it means is that there are forms of air action other than those carried out in direct co-operation with a navy or an army. For an air force now is more than a separate arm of the other two services.

Aircraft may be used for the observation of gunfire from battleships or to carry out photography prior to an attack by an army. These are examples of direct co-operation when aircraft may be looked upon as an arm of the other two services. On the other hand, take the situation in 1917 when the Germans were sinking so many ships by unrestricted submarine warfare, that food and other supplies in Great Britain were getting perilously short. Had the Germans had available at that time an efficient fleet of bombing aircraft the best way of utilizing them to increase the effect already being caused by submarines, would

not have been in direct co-operation with them by bombing British merchant ships at sea, but by attacking the port of London. This would not only have been within easier reach but would also have offered a more effective target. Again in June 1918, the Germans had advanced dangerously near Paris, and the *moral* of the French people was seriously affected. The most effective means of utilizing aircraft to increase the effect of the German army's success on the French people would not have been to bomb the French army entrenched on the flanks of the German salient but to attack Paris itself and its communications. These are examples of aircraft acting separately but in co-ordination with the action of a navy or an army. The nature of the objectives of an air force acting separately will be decided by a government in accordance with its general policy for the conduct of the war.

Control of sea communication may be a vital matter, in which case a government might decide that the objectives were to be such as would best assist its navy to carry out this duty. To gain complete control necessitates destruction of the enemy's main fleet. Merely containing a fleet *i.e.*, bottling it up in harbour, is not so effective as destruction. In the past the chief difficulty has not been so much in defeating the enemy fleet as in bringing it to action; this mainly because a hostile fleet can avoid battle by taking refuge in a protected harbour. It is not impossible that by continuous attack with bombs and torpedoes, aircraft may in another war force an enemy fleet out of harbour, or else reduce it to impotence if it refuses to move. Or the objective might be the enemy centre of government, in which case attacks would be made on buildings housing his various ministries and on the communication system. Again the duty assigned to an air force might be to bring about a continual dislocation of the normal life of the enemy people; and the objectives would then be centres of production, railways, docks and shipping or water and lighting systems.

How far air forces in another war will attack centres of population with the deliberate intention of terrorizing the inhabitants is an open question. Such a method of conducting war is opposed to all instincts of chivalry. It will, after the war, react on the moral condition of the nation that started it and, to quote from an article by Marshal Foch:—"La guerre n'est pas le but suprême, car au-dessus d'elle il y a la paix." On the other hand, it will usually be a very effective method of bringing pressure to bear. It was resorted to, although on a very small scale, in the World War; and when a nation's existence is at stake, it is unlikely to be bound by any rules, but only by expediency. The conclusion to be reached is that such action is well within the bounds of possibility and therefore that every step must be taken to meet such action on the part of an enemy.

Action Against Hostile Air Forces.—As has been said above, a navy cannot carry out completely its main function, *i.e.*, control of overseas communications until the enemy's main battle fleet is destroyed—hence destruction of this fleet becomes its primary object. Similarly the primary object of an army is the destruction of the enemy's army; destruction in both cases being that of the fighting value and being therefore moral as well as physical. It has frequently been argued that because this has been proved correct in the case of the older services it must apply to air forces as well and that their primary object must be to destroy the enemy air force. This argument fails to take into account the peculiar characteristics of aircraft. Firstly, as has been stated above, they possess great freedom of movement, can act very quickly and can take advantage of wind and clouds to conceal their movements. All this means that it is exceedingly difficult to stop them. Secondly there is nothing in air fighting corresponding with a defensive attitude in land fighting, where the defender takes up a position in which he is able to compel the attacker to fight or else abandon his object. An air force cannot entrench itself behind barbed wire to protect a vital area, because the attacker can move in three dimensions; it cannot take up a waiting position on the flank of its enemy's line of advance because the attacker may approach from any direction. Thirdly, difficult as it has been in the past to bring an enemy fleet to

action, it is still more difficult to bring an enemy air force to action; he cannot be compelled to take the air at the required moment, nor is it possible to wait indefinitely for him, because of the limitations of petrol capacity. Fourthly, air fighting is in its nature indecisive. We can hardly ever hope to destroy an enemy's air force, we can never ensure a permanent command of the air; all we can do is to obtain a local and temporary superiority. There will be much fighting in the air, there will usually be a continuous struggle for this local superiority, but there will be nothing corresponding to a decisive naval engagement or to a Gravelotte or a Sedan. Fifthly, fighting in the air is not an end in itself, it is only the means to an end, that end being to bring such pressure to bear upon the enemy people that they will force their government to sue for peace and do this as quickly as possible. Defeat of the enemy air force, even if it were possible, will not in itself contribute much towards this pressure, nothing corresponding to a decisive victory over the enemy's army. The ordinary man, accustomed as he is to movement only on the surface of the land, may see a dozen of his country's machines brought down in flames or may hear that one of the aerodromes of his bombing squadrons has been badly damaged, but he will not be overcome with despair. What does affect him is the fact that his railway has been broken so that he cannot get home, that his club can give him no dinner because the water supply is cut and that the town is in darkness because the power station is destroyed.

The situation of an air force is similar to that of a reconnoitring party, though on a different scale. In a paragraph dealing with the action of troops employed on reconnaissance it is laid down in the Army Field Service Regulations (August 1924): "The enemy's advanced troops will be engaged only if the commander considers this will be the best means of accomplishing his mission." This argument does not imply that an air force may expect to carry out its duties without fighting; it will have to fight, and fight hard to reach its objectives for attack. But it does imply this, that if its mission is to attack the enemy centre of government, it will not begin by concentrating all its efforts in an attempt, almost certainly a vain one, to destroy the enemy air force, for to do so would be to throw away one of the greatest assets of aircraft, the power to act simultaneously with the declaration of war. It will attack the enemy centre of government at once, will make these attacks its main object and regard fighting in the air as a diversion, whatever the extent of the fighting may be. For continued attacks on one area will undoubtedly lead to fighting in the air, and the more localized the attacks the more intensive the fighting. This was what occurred in France in the World War. At that time the mission of the British air service was co-operation with the army. This co-operation took place mainly over a narrow belt in which the enemy fighters were certain to find our co-operation aircraft. To enable these to carry out their work a continuous offensive was carried out against the enemy fighting machines, but as was laid down at the time this offensive was not an end in itself, only the means by which the main mission assigned to the air service could be accomplished. Further, at no time could our air force be said to have obtained more than a local and temporary superiority; the enemy air force on the Western front could never be said to have been definitely defeated, yet in spite of this the army co-operation squadrons carried on with their work. Had they waited till victory in the air had been won, they would have made but little progress with their mission.

Employment of Aircraft.—Aircraft are essentially offensive weapons, and it is only when they are used offensively that their potentialities can be utilized. Any use of aircraft in a purely defensive rôle is an anachronism. A large number of squadrons are detailed for the defence of England, but two-thirds of them are to defend by attacking the enemy; the remainder are fighting squadrons on the defensive only in so far as they lie in wait for the enemy's approach, but, from that event onwards, wholly offensive in their action; all the ground organization of observer posts, lights, communications to some extent, the anti-aircraft guns, can be looked upon as forming a prepared battleground for the purpose of enabling the fighter squadrons to carry

out their attacks with success. Similarly close escorts of fighters to bombing formations are wrong, because the fighters will be tied down to the bombers, will be limited to defensive action, and will be unable to make use of their speed and power of manoeuvre. If action against an enemy air force is necessary in order that the bombers may reach their target, the correct method of operation for the fighters is to attack the enemy aircraft either at their own aerodromes or in the air, synchronizing these attacks with the movements of the bombers.

The mobility of aircraft is a great asset, and must be utilized to the full in order to concentrate effort on the decisive object. This mobility is not only a matter of moving quickly from one part of the world to another, but also of the power to use the same machines for many different purposes whether it be over the sea or over the land. The mobility and freedom of action of aircraft confer great potentialities for surprise which must be exploited to the utmost. These same assets may also tend to lead to a dispersal of any available force of aircraft; this is wrong and must be guarded against; concentration of effort is as essential in the air as on land or sea.

The extent to which aircraft can bomb battleships is still a subject of discussion, but there is no doubt that they are able to sink or disable merchant ships, either by bombs or torpedoes. Under the Washington Agreement, which has, however, never been ratified, it is laid down that merchant ships must be visited and searched before seizure, and further that they must not be destroyed unless adequate arrangements are made for the safety of the crews. At the present time this agreement is not held to apply to aircraft, but only to fighting ships. Should the agreement eventually be applied to aircraft it would be very difficult for them to act by themselves against merchant shipping, but, as stated above, when considering the bombing of centres of population we cannot be certain that our enemies in another war will comply with any agreement that may be made on the subject. In any case, in co-operation with warships aircraft will be of great value, both in scouting for merchant vessels and also in forcing them to heave to until one of their own warships can arrive. They will also possibly act effectively against forts and seriously hamper work in them. Aircraft must, therefore, be regarded as an added danger to overseas communications. On the other hand, experience in the War of 1914-1918 showed that aircraft were very valuable for anti-submarine defence and their mere presence with a convoy was nearly always sufficient to secure it against submarine attack. In 1918 out of 7,000 convoys which had aircraft escort, only six were attacked by submarines.

Aircraft in Tribal Operations.—Aircraft have proved of the utmost value for the control of semi-civilized or uncivilized countries and for carrying out those classes of wars which may be grouped under the term of tribal operations. In the past, when the operations were carried out on the ground, there have been four main difficulties to contend with:—(1) that of movement owing to the absence of roads and railways; (2) that of supply owing to the country being usually barren; (3) that of closing with the enemy owing to his superior mobility; (4) that of acting rapidly. Although but a small force would be needed to defeat the enemy, that force required a line of communications, frequently a long one. This line of communications had to be protected and this generally necessitated a much larger force than was required to defeat the enemy. As a result a large number of men, animals and supplies had to be collected before the operations could commence.

All these difficulties are avoided by the use of aircraft. Acting from a secure base they can operate up to 200 miles or more without the need for any line of communications, other than that from their home country to their base, or for any troops to guard one. The nature of the country forms no obstacle to their movement and their speed is far greater than anything the enemy can attempt. Provided, therefore, that the distances are not too great, aircraft are able to act within a few hours, whereas previously the preparations took weeks, or even months. This rapidity of action is an invaluable asset; any rising that takes place in uncivilized countries is usually small and local in the first instance

but if left unchecked will quickly spread. Aircraft can usually nip trouble in the bud. But the value of aircraft lies not only in carrying out tribal operations but in obviating their necessity. It must be remembered that a tribesman usually fights for two reasons; firstly, he is poor and wants loot, secondly, he likes fighting for its own sake provided the odds are in his favour. Aircraft offer him neither of these two allurements. There is no line of communication to raid with the probability of obtaining boots and ammunition, no camps from which to steal camels and rifles, no pickets to be surprised and overwhelmed by superior numbers. All he can do is to fire away valuable ammunition at targets which, if hit, are seldom brought down and even then are useless to him. Again, in the control of a country, ground forces act mainly by occupation. This leads to the establishment of a large number of small posts which are often isolated and difficult to supply, reinforce or relieve. They form tempting objectives to unruly natives. On the other hand, when aircraft control a country there is no need for dispersion and isolation. Because of their potentiality for rapid action at a distance, they can be concentrated in one or two secure spots and still be able to deal with any disturbance in a few hours, either by taking a political officer to confer with the malcontents, by dropping leaflets, by demonstration flights or by actual attack.

Aircraft and Imperial Defence.—We may now apply these generalities to problems of the defence of the British empire. There was a time when Great Britain was exposed to the danger of an invasion and adopted extensive measures of protection. Invasion is hardly within the bounds of possibility to-day but Great Britain is exposed to another form of attack from the air. In the last war a few desultory raids were carried out on this country, but even then the effects were by no means negligible. The total weight of bombs dropped by aeroplanes on London was under thirty tons, the machines were unsuitable for their job and the *moral* of the squadron that carried out the attacks was low. The casualties, however, amounted to 441 killed and 1,244 injured. Besides this the moral effect was great:—for instance, the number of people who took refuge in the tubes increased from 100,000 on Sept. 24, 1917, to 300,000 on Feb. 16, 1918. Serious dislocation was caused to the work on munitions and to railway traffic.

In the future it will be necessary to prepare to face not spasmodic attacks of this nature but determined and serious attacks and these, it must be remembered, will be delivered straight against the heart and brain of the empire and may in themselves form the declaration of war. London is badly situated for defence against aircraft attack. It is close to the coast on the east and south, which means that not only will warnings of impending attacks be very short, but also that the enemy will be able to take advantage of winds to reduce still further the period during which he is obliged to remain over British soil; the time available to the defending squadrons to get off, climb to the necessary height, find and stop the enemy will often be less than twenty minutes. Another added danger lies in attacks of aircraft on merchant shipping. If a map of ocean trade routes be opened and thereon is painted the area within range of foreign aircraft bases, this area will be found to cover most of our trade routes at one point or another. This is particularly impressive in the Mediterranean. So far the development of aircraft tends to add to the difficulty of imperial defence—but there is another side to the picture.

Aircraft forms a most effective means of defence against the possibility of overseas invasion. The invading force can be attacked while still many miles out at sea and such attacks are likely to result in severe damage both to transport and to the *moral* of the troops they carry. Again, during the process of disembarkation, ships at anchor and men in open boats, form easy targets to aircraft. In fact it is now generally admitted that landing on a hostile coast is impracticable unless air superiority has first been obtained. It would be difficult to do this unless a land base is first established within easy range of the defenders, since aircraft working from carriers are at a serious disadvantage when opposed to aircraft working from land. It would therefore appear

that aircraft forms a most valuable means of coast defence for certain parts of the empire such as Australia. And there is a further point to remember. Guns mounted for coast defence are fixed and immobile. They represent a very large capital expenditure which can be used for no other purpose and may never be required at all. Substitute aeroplanes for guns and we not only have the means of attacking the hypothetical invader at a vastly greater range, but we can use these aircraft for other purposes. A squadron at, say, Singapore may be sent to prevent trouble on the north-west frontier of India and if the situation in the Far East became serious could be moved back to Singapore at short notice.

It would manifestly be expensive to keep enough aeroplane squadrons to meet all possible eventualities in any part of the world and there is no necessity to do so. Aircraft are very mobile; aeroplanes have already flown to every part of the British empire in the eastern hemisphere and all that remains is to develop these imperial air routes that have already been blazed. Such an air route from Cairo, through Palestine and Iraq to India, and on via Burma to Singapore and Australia, would give possibilities of the utmost value for rapid concentration at any threatened or troublesome spot and such power of concentration would have great deterrent effect against a potential enemy. With another route from Cairo to the Cape, with a branch to Nigeria, the problem of imperial defence and control assumes another aspect. These routes may be regarded as the modern counterparts of the roads which linked up the parts of the Roman empire. But to gain value from them we must never look upon aeroplane squadrons as fixed garrisons but as mobile units, located normally at some station but ready to move to any point.

AIRWAY, an artery of a mine, along which the ventilation is conducted. The districts branching from the fresh air "intakes" are ventilated by "splits" taken off the main airway. The current conducted along the branch or district intakes, round the "working face," returns by the district "return airway," enters the main "return airway" and proceeds thence to the upcast shaft up which it is drawn to the surface by fans. This is the practice in coal-mining in Great Britain. In France the ventilation is generally carried out by compression, that is by fans forcing the air down the "downcast" shaft and through the workings to the "upcast."

The position, number and arrangement of the airways in an ideal coal mine are shown in the figure overleaf, as well as the manner in which the air is "split" for district ventilation. (See also COAL-MINING: *Ventilation*.) See Diagram overleaf. (R. R.)

AIRY, SIR GEORGE BIDDLELL (1801-1892), British astronomer royal, was born at Alnwick on July 27, 1801. He was educated at Colchester grammar school and at Trinity college, Cambridge, where he graduated as senior wrangler in 1823. He became a fellow of his college (1824), Lucasian professor of mathematics (1826), and then (1828) Plumian professor of astronomy and director of the new Cambridge observatory. Before long a mural circle was installed, and regular observations were instituted with it in 1833. In the same year the duke of Northumberland presented the Cambridge observatory with a fine object-glass of 12 in. aperture, which was mounted according to Airy's designs and under his superintendence, although the erection was not completed until after his removal to Greenwich in 1835. Airy's writings during this time are divided between mathematical physics and astronomy. The former were for the most part concerned

DIAGRAM ILLUSTRATING THE INSTALLATION OF AIRWAYS AND VENTILATING CURRENTS IN MINES—(SEE PAGE 477)

The upper plan shows the shaft pillars and the position of the main airways in the neighbourhood. The lower plan shows the main and district airways. The arrows in both plans indicate the direction of inward and outward air currents which make up the system of ventilation below ground

with questions relating to the theory of light, arising out of his professorial lectures, among which may be specially mentioned his paper "On the Diffraction of an Object-Glass with Circular Aperture." Of his astronomical writings during this period the most important are his investigation of the mass of Jupiter, his report to the British Association on the progress of astronomy during the 19th century, and his memoir *On an Inequality of Long Period in the Motions of the Earth and Venus*.

Airy's discovery of a new inequality in the motions of Venus and the earth was a remarkable achievement. In correcting the elements of Delambre's solar tables he discovered an inequality overlooked by their constructor. Eight times the mean motion of Venus is so nearly equal to 13 times that of the earth that the difference amounts to only the $\frac{1}{240}$ th of the earth's mean motion, and from the fact that the term depending on this difference, although very small in itself, receives in the integration of the differential equations a multiplier of about 2,200,000, Airy was led to infer the existence of a sensible inequality extending over 240 years (*Phil. Trans.*, cxxii. 67). The investigation leading to this result was probably the most laborious that had been made up to Airy's time in planetary theory, and represented the first specific improvement in the solar tables effected in England since the establishment of the theory of gravitation.

In June, 1835, Airy was appointed astronomer royal in succession to John Pond. Under Airy's administration modern apparatus was installed, and the whole organization placed on a scientific footing. No fewer than 8,000 lunar observations were rescued from oblivion, and were, in 1846, placed at the disposal of astronomers in such a form that they could be used directly for comparison with the theory and for the improvement of the tables of the moon's motion. (See HANSEN, PETER ANDREAS.)

One of the most remarkable of Airy's researches was his determination of the mean density of the earth. In 1826 the idea occurred to him of attacking this problem by means of pendulum experiments at the top and bottom of a deep mine. After some failures, successful experiments were made at the Harton pit, near South Shields, in 1854. Their immediate result was to show that gravity at the bottom of the mine exceeded that at the top by

$\frac{1}{19,286}$ th of its amount, the depth being 1,256ft. From this Airy was led to the final value of 6.566 for the mean density of the earth as compared with that of water (*Phil. Trans.* cxlvi. 342). At the age of 71 Airy embarked on a new method of treating lunar theory. A general description of his method will be found in the *Monthly Notices of the Royal Astronomical Society*, Vol. xxxiv. No. 3. It consisted essentially in the adoption of Delaunay's final numerical expressions for longitude, latitude and parallax, with a symbolic term attached to each number, the value of which was to be determined by substitution in the equations of motion. The work was published in 1886, when its author was 85 years of age. In 1881 Sir George Airy resigned the office of astronomer royal and resided at the White house, Greenwich, not far from the Royal observatory, until his death, which took place on Jan. 2, 1892. The learned societies of his own and other countries conferred many honours on him.

BIBLIOGRAPHY.—A list of Airy's papers will be found in his *Autobiography*, edited in 1896 by his son, Wilfrid Airy, B.A., M. Inst. C.E. See also his *Mathematical Tracts* (1826) on the *Lunar Theory*, *Figure of the Earth*, *Precession and Nutation*, and *Calculus of Variations*, to which, in the second edition (of 1828), were added tracts on the *Planetary Theory* and the *Undulatory Theory of Light*; *Experiments on Iron-built Ships*, instituted for the purpose of discovering a correction for the deviation of the Compass produced by the Iron of the Ships (1839); *On the Theoretical Explanation of an apparent new Polarity in Light* (1840); *Tides and Waves* (1842).

AISLABIE, JOHN (1670–1742), English politician, born Dec. 7, 1670. He was made chancellor of the Exchequer in 1718, and supported the proposal of the South Sea Company to pay off the national debt. At the collapse of the company he was imprisoned in the Tower with other politicians accused of attempting to profit fraudulently from the scheme, but was soon released, through Walpole's intervention.

AISLE, in architecture, a term primarily meaning the wing of a house, but more commonly used to indicate any long, narrow space separated from the remainder of the building by a line of piers, columns or arches. It is specially used to designate the lateral portions of a church or other large room in which interior supports occur. The term also has come to mean a passageway,

specialty a passageway between groups of seats, as in a church or theatre. From the time of the early Christian basilica, the use of one or more side aisles flanking a central nave has been almost universal in church building, and church aisles are known as nave aisles, transept aisles or choir aisles from their position in relation to the nave, transept or choir. The choir aisle around the east end of a choir is known as an ambulatory (*q.v.*). In the normal Romanesque or Gothic church the roof of the aisles is lower than the central nave; but in certain examples in southern France (*e.g.*, St. Nazaire, Carcassonne), in Spain (*e.g.*, Barcelona), and especially in Germany, where for the smaller churches it is almost normal, the nave and aisles are of the same height. A church with nave flanked by one aisle on each side is known as a three-aisle church; one with two side aisles on each side as a five-aisle church, and so on.

AISNE, department, northern France, west of Ardennes (*q.v.*). Area 2,866sq.m. Pop. (1926) 488,999. It touches the western end of the Ardennes (930ft.) in the north-east, but its surface is all of secondary or tertiary rocks. The outlying masses of the latter, often with steep flanks, form important sites such as that of Laon, the capital, and the famous *Chemin des Dames*. The Aisne enters the department from the east just as it leaves the chalk scarp and flows west to the Oise, the other river of the department. It has been made to stretch down to include the deep Château-Thierry portion of the Marne valley, too far west to focus on Épernay or Reims and allied to the hill country farther north rather than to Paris on the west. The department was the scene of much of the World War. It had a number of forests, but it lacks metallic ores, though quarries yield building stone, gypsum and clay. Mostly in the belt of rainfall 600–800mm., and well watered and sheltered, it has had great farming prosperity, with specialization in dairying towards the north-east. Of the towns, Guise in the north does agricultural and other engineering and St. Quentin and numerous villages do weaving of cotton, wool and silk. St. Gobain has made mirrors since the 17th century. Sugar has been an important crop and industry. Communications are good by rail and by navigable rivers (Aisne, Oise, Marne). St. Quentin, Vervins, Laon and Soissons give their names to arrondissements and are, with Château-Thierry and Hirson (*q.v.*), the chief towns. This department and that of Oise were rich in architectural monuments several of which are now ruined, but the churches at Laon, Braine and Urcel (mainly 12th century) have survived the devastation and the splendid *Basilique* of S. Quentin has been largely repaired, while the castle-ruin (1400) of La Ferté-Milon has not suffered. Soissons is the seat of a bishop in the province of Reims, the court of appeal is that of Amiens (Somme), which is also the centre of the 2nd Army Corps. The department belongs to the educational province (*académie*) of Douai.

Aisne, Battle of the, 1918.—This title is one of several alternatives used to designate the third great German offensive of 1918, launched on May 27, against the *Chemin des Dames* ridge and rapidly carried across the Aisne and southward to the Marne. It is described under **CHEMIN DES DAMES, BATTLE OF THE, 1918**.

AÏSSÉ (a corruption of HAÏDEE), MADemoiselle (*c.* 1694–1733), French letter-writer, was the daughter of a Circassian chief, and was born about 1694. Her father's palace was pillaged by the Turks, and as a child of four years old she was sold to the comte de Ferriol, the French ambassador at Constantinople. She was brought up in Paris by Ferriol's sister-in-law with her own sons, MM. D'Argental and Pont de Veyle. Her great beauty and romantic history made her the fashion, and she attracted the notice of the regent, Philip, duke of Orleans, whose offers she had the strength of mind to refuse. She formed a deep and lasting attachment to the Chevalier d'Aydie, by whom she had a daughter. She died in Paris on March 13, 1733. Her letters to her friend Madame Calandrini contain much interesting information with regard to contemporary celebrities, especially on Mme. du Deffand and Mme. de Tencin, but they are above all of interest in the picture they afford of the writer's own tenderness and fidelity.

Her *Lettres* were edited by Voltaire (1787), by J. Ravenel, with a notice by Sainte-Beuve (1846) and by Eugène Asse (1873). *Mlle.*

Aïssé has been the subject of three plays: by A. de Lavergne and P. Woucher (1854), by Louis Bouilhet (1872) and by Dejou (1898). See also Courteault, *Une Idylle au XVIII^e siècle, Mlle. Aïssé et le Chevalier d'Aydie* (Maçon, 1900); and notices prefixed to the editions of 1846 and 1873. There is an interesting essay by Sir E. Gosse in his *French Profiles* (1905).

AITKIN, ROBERT GRANT (1864–), American astronomer, was born in Jackson, Calif., on Dec. 31, 1864. He was educated at Williams college, Williamstown, Mass., from which he graduated in 1887 and received the degree of M.A. in 1892. In 1888–91 he was instructor of mathematics in Livermore college, and from 1891 to 1895 he was professor of mathematics and astronomy in the University of the Pacific. In 1895 he was appointed astronomer at Lick observatory, Mt. Hamilton, Calif., of which he was made associate director in 1923. Here he specialized in the study of double stars, of which he discovered more than 3,000. For these discoveries he was awarded in 1906 the Lalande prize by the Academy of Sciences of France. His published writings include *Binary Stars* (1918) and numerous articles contributed to astronomical and other scientific journals.

AITON, WILLIAM (1731–93), Scottish botanist, was born near Hamilton in 1731, and died on Feb. 2, 1793. As director of Kew Gardens (1759–93) he effected many improvements, and in 1789 he published *Hortus Kewensis*, a catalogue of the plants there cultivated. A second and enlarged edition of the *Hortus* was brought out in 1810–13 by his eldest son, WILLIAM TOWNSEND AITON (1766–1849), who succeeded him at Kew.

AITZEMA, LIEUWE (LEO) VAN (1600–1669), Dutch historian and statesman, was born at Doccum, in Friesland, Nov. 19, 1600, and died at The Hague, Feb. 23, 1669. His most important work was the *Saken van Staet in Oorlogh in ende omtrent de Vereenigte Nederlanden* (1655–71), embracing the period from 1621 to 1668. It contains a large number of state documents, and is an invaluable authority on one of the most eventful periods of Dutch history.

Four continuations of the history, by the poet and historian Lambert van den Bos, were published successively at Amsterdam in 1685, 1688, 1698 and 1699. The *Derde Vervolg Zijnde het vierde Stuck van het Vervolg op de Historie*, etc., brings the history down to 1697.

AIVALI, a town on the west coast of Asia Minor (vilayet of Karasi), opposite the island of Mitylene. Pop. (1927), 16,744. It stands near the site of the Aeolian *Heraclea*, on rising ground at the end of a bay which is separated from the Gulf of Adramyttium, and protected from the prevailing winds by the Moschonisi islands (*Hecatonnesoi*). It was formerly an exclusively Greek town; the Greek population was "exchanged" for Muslim immigrants in 1924.

AIX, city of south-east France, capital of an arrondissement in the department of Bouches-du-Rhône, 18m. N. of Marseille. Pop. (1926) 23,402. It is situated in a plain overlooking the Arc, about a mile from the right bank of the river. Aix (*Aquae Sextiae*) was founded in 123 B.C., by the Roman consul Sextius Calvinus. In 102 B.C. it was the scene of the defeat of the Cimbri and Teutones by Marius. In the 4th century it became the metropolis of Narbonensis Secunda. Occupied by Visigoths in 477, and repeatedly plundered by Franks and Lombards, it was taken by Saracens in 731. During the middle ages it was the capital of the county of Provence and reached its zenith after the 12th century, when the houses of Aragon and Anjou made it an artistic centre and seat of learning. It passed with Provence to the crown in 1487, and had the parlement of Provence (1501–1789). In the 17th and 18th centuries it was the seat of the *intendance* of Provence.

The Cours Mirabeau divides the town into the new town to the south and the old town to the north. Aix is the seat of the faculties of law and letters of the University of Aix-Marseille. The cathedral of St. Sauveur dates from the 11th, 12th and 13th centuries. It has a rich Gothic portal with elaborately carved doors. The archbishop's palace and a Romanesque cloister adjoin the cathedral on its south side. The church of St. Jean de Malte (13th century), contains valuable pictures. The *hôtel de ville* (17th century) contains fine wood-work and a large library

with valuable mss. Aix has thermal springs, remarkable for their heat and containing lime and carbonic acid; baths have been built (1705) near the site of the Roman baths. The industries include flour-milling, the making of confectionery, the manufacture of hats and the preparation of olive-oil. Trade is in olive-oil, almonds and flour.

The town, which is the seat of an archbishop and court of appeal and the centre of an *académie*, has a court of assizes, tribunal of commerce, and a chamber of arts and manufactures. It

THE SQUARE IN AIX SHOWING THE COURT HOUSE AND CLOCK TOWER

also has museums of antiquities, natural history and painting, and several learned societies.

Aix, Battle of (Aquæ Sextiæ).—After the Roman disaster at Arausio (*q.v.*) in 105 B.C. the great migration of the Cimbri and Teutones turned aside to Spain, thus enabling Marius (*q.v.*) to gain breathing space to organize and train his "new model" army. But in 102 B.C., returning to Gaul, these tribes moved to invade Italy, the Cimbri going round the north of the Alpine barrier and the Teutones by the Mediterranean coast. On their approach Marius entrenched himself and refused to be drawn out to battle, content to repulse their assault and to acclimatize his men to the sight and ways of their strange and terrifying foe. When the host passed onwards, Marius cautiously followed until on reaching Aquæ Sextiæ, now Aix, 20m. N. of Marseille, a partial engagement was brought on by the common desire to gain possession of the only available water supply. The Romans were successful and after a two days' pause, Marius judged the moment ripe for battle, having detached a force of 3,000 men to take up a concealed position on the enemy's flank. His cavalry and light infantry were then used to draw out the Teutones to attack, which Marius awaited on the slope of a hill. This first onslaught was stopped with difficulty, but gradually the Romans pressed their assailants downhill. Before the Teutones could reform on the level, they were struck in rear by the flank detachment, and their very numbers then intensified the press and their difficulty. The disaster was so complete that not merely the menace but the tribe itself was dispersed.

See Henry Bordeaux, *La Vallée d'Aix* (1921); M. A. E. Clerc, *Aquæ Sextiæ* (1916).

AIX-LA-CHAPELLE: see AACHEN.

AIX-LA-CHAPELLE, CONGRESSES OF. Three congresses have met at Aix-la-Chapelle—in 1668, in 1748 and in 1818.

1. The treaty of May 2, 1668, which ended the War of Devolution, was the outcome of that of St. Germain signed on April 15 by France and the representatives of the Triple Alliance. The Treaty of Aix-la-Chapelle left to France all the conquests made in Flanders during 1667, with all their "*appartenances, dépendances et annexes*," a vague provision of which, after the peace of Nimwegen (1680), Louis XIV. took advantage to occupy villages and towns adjudged to him by his *Chambres de réunion* as dependencies of the cities and territories acquired in 1668. On the other hand, France restored to Spain Cambrai, Aire and Saint-Omer, as well as Franche Comté. The Treaty of Aix-la-Chapelle was placed under the guarantee of Great Britain, Sweden and Holland, by a

convention signed at The Hague on May 7, 1669, to which Spain acceded.

See Jean du Mont, baron de Carlsroon, *Corps universel diplomatique* (Amsterdam, 1726-31).

2. On April 24, 1748, a congress assembled at Aix-la-Chapelle to end the War of Austrian Succession. The definitive treaty was signed on Oct. 18. Its most important provisions were those stipulating for (1) a general restitution of conquests, including Cape Breton to France, Madras to England and the barrier towns to the Dutch; (2) the assignment to Don Philip of the duchies of Parma, Piacenza and Guastalla; (3) the restoration of the duke of Modena and the republic of Genoa to their former positions; (4) the renewal in favour of Great Britain of the Asiento contract of March 16, 1713, and of the right to send an annual vessel to the Spanish colonies; (5) the renewal of the article of the treaty of 1718 recognizing the Protestant succession in the English throne; (6) the recognition of the emperor Francis and the confirmation of the pragmatic sanction, *i.e.*, of the right of Maria Theresa to the Hapsburg succession; (7) the guarantee to Prussia of the duchy of Silesia and the county of Glatz.

Spain having raised objections to the Asiento clauses, the Treaty of Aix-la-Chapelle was supplemented by that of Madrid (Oct. 5, 1750), by which Great Britain surrendered her claims for a sum of £100,000.

See Comte G. de Garden, *Hist. des traités de paix*, iii. p. 373 (1848-87).

3. The congress or conference of Aix-la-Chapelle in 1818 was primarily a meeting of the four Allied Powers—Great Britain, Austria, Prussia and Russia—to decide the question of the withdrawal of the army of occupation from France and the consequent international relationships of the Powers. The congress, which opened on Oct. 1, was attended by Alexander I. of Russia, Francis I. of Austria, and Frederick William III. of Prussia, in person. Great Britain was represented by Lord Castlereagh and the duke of Wellington, Austria by Prince Metternich, Russia by Counts Capo d'Istria and Nesselrode, Prussia by Prince Hardenberg and Count Bernstorff. The duc de Richelieu, by favour of the allies, was present on behalf of France. The evacuation of France was agreed to in principle at the first session, the consequent treaty being signed on Oct. 9. The rest of the time of the congress was mainly occupied in discussing the form to be taken by the European alliance, and the precautions to be adopted against a fresh outburst on the part of France. The proposal of Alexander I., to establish a "universal union of guarantee" on the broad basis of the Holy Alliance, broke down on the opposition of Great Britain; and the main outcome of the congress was the signature, on Nov. 15, of two instruments: (1) a secret protocol confirming and renewing the Quadruple Alliance established by the treaties of Chaumont and Paris (Nov. 20, 1815) against France; (2) a public "declaration" of the intention of the Powers to maintain their intimate union, of which the object was to preserve peace on the basis of respect for treaties. The secret protocol was communicated in confidence to Richelieu; to the declaration France was invited publicly to adhere.

The congress also concerned itself with the questions of the suppression of the slave trade and the Barbary pirates. In neither case was any decision arrived at, owing (1) to the refusal of the other Powers to agree with the British proposal for a reciprocal right of search on the high seas; (2) to the objection of Great Britain to international action, which would have involved the presence of a Russian squadron in the Mediterranean. A great variety of lesser questions was considered, but an attempt to introduce the subject of the Spanish colonies was defeated by the opposition of Great Britain. The congress represents the highest point reached in the attempt to govern Europe by an international committee of the Powers.

See W. Alison Phillips, *The Confederation of Europe* (2nd. ed. 1919). (W. A. P.)

AIX-LES-BAINS, thermal spa and fashionable resort, east France, in the department of Savoie, near the Lac du Bourget, 9m. by rail N. of Chambéry. Pop. (1926) 7,891. The sulphur springs were known as *Aquæ Gratianæ* by the Romans, and the

BEING ARMED WITH A THUNDERBOLT, FROM THE CAVES OF AJANTA**

The illustration was taken from Cave I. There are about 30 caves excavated in the south side of the bank of the ravine of the river Wagura, some three and a half miles from Ajanta, India, which were used as dwellings and meeting-halls by the Buddhist Order from 200 B.C. to the seventh century A.D. Many of the interior walls of these caves are covered with fresco paintings, which are very decorative. These have been preserved and form an important body of evidence of pre-Hindu art in India

neighbourhood has numerous ancient remains. Over 50,000 visitors are attracted annually; the main season is July–September, but Aix also serves as a base for Alpine winter sports.

AIYAR, SIR SHESHADRI (1845–1901), Indian statesman, the son of a Brahman of Palghat, Malabar, rose from a humble position as translator in his native district to be prime minister of Mysore under the Maharaja Chamarajendra. To him Mysore owes many important public works and the development of the Kolar gold-fields. Aiyar retired in 1900 and died on Sept. 13, 1901.

AIYAR, SIR TIRUVARUR MUTUSWAMY (1832–1895), native Indian judge of the high court of Madras, was born of poor parents in the village of Vuchuwadi, near Tanjore, on Jan. 28, 1832. His widowed mother was forced by poverty to remove with Mutuswamy and his brother to Tiruvarur, where the former learnt Tamil, and soon set to work under the village accountant at a monthly salary of one rupee. Aiyar worked his way through a series of minor offices until he was able to take his degree in law. He then became a judge of the Madras small causes court, and in 1878 he was raised to the bench of the high court, which office he occupied with ability and distinction for over fifteen years, sometimes acting as the chief justice. He attended by invitation of the viceroy the imperial assemblage at Delhi in 1877. In 1878 he received the honour of C.I.E. and in 1893 the K.C.I.E. was conferred on him. He died suddenly in 1895. Aiyar took his full share in the affairs of the Madras university, of which he was nominated a fellow in 1872 and a syndic in 1877, and was well acquainted with English law, literature and philosophy. He was through life a staunch Brahman, devout and amiable in character, with a taste for the ancient music of India and the study of the Vedas and other departments of Sanskrit literature.

AJACCIO, capital of Corsica, on the west coast of the island. Pop. (1926) 20,797. Ajaccio occupies a sheltered position at the foot of wooded hills on the north shore of the Gulf of Ajaccio. The harbour, to the east, is protected on the south by a peninsula which carries the citadel. To the south-west of this peninsula lies the Place Bonaparte, frequented by winter visitors attracted by the mild climate. Apart from one or two fine thoroughfares, the streets are narrow and the town has a deserted appearance. The present town of Ajaccio lies about two miles to the south of its original site, from which it was transferred by the Genoese in 1492. Occupied in 1553 by the French, it again fell to the Genoese after the treaty of Cateau Cambrésis in 1559. The town finally passed to the French in 1768. Since 1810 it has been the capital of the department of Corsica. The associations of Napoleon I. with the town are everywhere emphasized by street-names and statues. The town is the seat of a bishopric (7th century) and of a prefect. It has tribunals of first instance and of commerce and a museum. Ajaccio makes cigars and macaroni and carries on shipbuilding, sardine-fishing and coral-fishing. Its exports include timber, citrons and skins.

AJAIGARH, an Indian state in Bundelkhand, under the Central India agency. It has an area of 802sq.m., and a population in 1921 of 84,790. The chief, who is a Bundela Rajput, bears the title of sawai maharaja and has a salute of eleven guns. He resides at the town of Naushahr, at the foot of the hill-fortress of Ajaigarh, from which the state takes its name. This fort is situated on a very steep hill, more than 800ft. above the town, and contains the ruins of temples with elaborate sculptures.

AJANTA (more properly Ājunthā), a village in the dominions of the Nizam of Hyderabad in India, celebrated for its cave hermitages and halls, in a wooded and rugged ravine about 3½m. from the village. The ravine is that of the river Wāgura which falls from the east over a bluff forming several waterfalls. The caves, about 30 in number, are excavated in the south side of the precipitous bank of the ravine, and are of two kinds—dwelling-halls and meeting-halls. The former have a broad verandah, its roof supported by pillars, and giving towards the interior on to a hall averaging in size about 35ft. by 20ft. Dormitories are excavated opening on to this hall, and an image of the Buddha usually stands in a niche facing the entrance. In the larger caves pillars support the roof on all three sides, forming a sort of cloister run-

ning round the hall. The meeting-halls which back into the rock about twice as far as the dwelling-halls, were used as chapter-houses for the meetings of the Buddhist Order. The oldest caves date from 200 B.C. to A.D. 200, the next belong approximately to the 6th, and the youngest to the 7th century A.D. Most of the interior walls of the caves are covered with fresco paintings, of considerable merit, and somewhat in the early Italian style. When first discovered, in 1817, these frescoes were in a fair state of preservation, but they fell later into decay. The remains are now properly preserved, and form, with copies of those destroyed, important evidence as to pre-Hindu art in India. Ajanta was a kind of college monastery.

AJAX (I.) *the Greater* Gr. Αἴας, son of Telamon, king of Salamis. In Homer's *Iliad* he is described as of great stature and colossal frame, second only to Achilles in strength and bravery. He engaged Hector in single combat and, with the aid of Athene, rescued the body of Achilles from the hands of the Trojans. In the competition between him and Odysseus for the armour of Achilles, Agamemnon, at the instigation of Athene, awarded the prize to Odysseus. This so enraged Ajax that it caused his death (*Odyssey*, xi. 541). According to a later and more definite story, accepted by Sophocles as the basis of his drama, his disappointment drove him mad; he rushed out of his tent and fell upon the flocks of sheep in the camp under the impression that they were the Greeks; on coming to his senses he slew himself with the sword which he had received as a present from Hector. From his blood sprang a red flower (see *HYACINTHUS*) which bore on its leaves the initial letters of his name AI, also expressive of lament (Pausanias i. 35. 4.). He was the tutelary hero of the island of Salamis, where he had a temple and an image, and where a festival called *Aianteia* was celebrated in his honour (Pausanias i. 35).

II., *the Lesser*, son of Oileus, king of Locris, called the "lesser" or Locrian Ajax, to distinguish him from the son of Telamon. In spite of his small stature, he held his own amongst the other heroes before Troy; he was brave, next to Achilles in swiftness of foot, and famous for throwing the spear. But he was boastful, arrogant, and quarrelsome. Athena wrecked his ship on his homeward voyage (*Odyssey*, iv. 499), presumably for his crime (not definitely mentioned by Homer) in dragging Cassandra from the statue of the goddess, during the sack of Troy, and violating her. This led to the thousand years' penance of his people; nevertheless, he was worshipped as a national hero by the Opuntian Locrians (on whose coins he appeared), who always left a vacant place for him in their battle line.

See articles in Roscher's *Lexikon* and Pauly-Wissowa, *Realencyklopädie*; L. R. Farnell, *Hero-Cults*, pp. 293 *et seq.* and 305 *et seq.*

AJMERE or **AJMER**, a city of British India in Rajputana, which gives its name to a district and also to a petty province called Ajmere-Merwara. It is situated on the lower slopes of Taragarh Hill, in the Aravalli mountains. To the north of the city is a large artificial lake called the Ana Sagar, and farther up the valley is a new lake, the Foy Sagar, from which the water supply of the place is now derived.

The chief object of interest is the *darga*, or tomb of the famous Mohammedan saint Muin-ud-din Chishti. It is situated at the foot of the Taragarh hill, and consists of a block of white marble buildings without much pretension to architectural beauty. To this place the emperor Akbar, with his empress, performed a pilgrimage on foot from Agra in accordance with the terms of a vow he had made when praying for a son. An ancient Jain temple converted about A.D. 1200 into a mosque, is situated on the lower slope of the Taragarh hill. With the exception of that part used as a mosque, nearly the whole of the ancient temple has fallen into ruins, but the relics are not excelled in beauty of architecture and sculpture by any remains of Hindu art. Forty columns support the roof, but no two are alike, and great fertility of invention is manifested in the execution of the ornaments. The summit of Taragarh hill, overhanging Ajmere, is crowned by a fort, the lofty thick battlements of which run along its brow and enclose the tableland. The walls are 2m. in circumference, and the fort can only be approached by steep and very roughly paved planes,

commanded by the fort and the outworks, and by the hill to the west. Ajmere was founded about the year A.D. 145 by Ajaipal, a Chauhan, who established the dynasty which continued to rule the country (with many vicissitudes of fortune) while the repeated waves of Mohammedan invasion swept over India, until it eventually became an appanage of the crown of Delhi in 1193. Its internal government, however, was handed over to its ancient rulers upon the payment of a heavy tribute to the conquerors. It then remained feudatory to Delhi till 1365, when it was captured by the ruler of Mewar. Akbar took it back in 1556; and it continued in the hands of the Moguls, with occasional revolts, till 1770, when it was ceded to the Mahrattas, from which time up to 1818 the unhappy district was the scene of a continual struggle, being seized at different times by the Mewar and Marwar rajas, from whom it was so often retaken by the Mahrattas. In 1818 the latter ceded it to the British in return for a payment of 50,000 rupees.

The modern city (pop. 113,512 in 1921) is an important administrative and railway centre. It is well laid out with wide streets and handsome houses. The city does an active trade in salt which is imported in large quantities from the Sambar lake and Ramsur. Oil-making is also a profitable branch of trade. Cotton cloths are manufactured to some extent, for the dyeing of which the city has attained a high reputation. The educational institutions include the Mayo Rajkumar college, opened in 1875, for training the sons of the nobles of Rajputana, on the lines of an English public school. Seven miles from Ajmere lies the lake of Pushkar, one of the most sacred pieces of water in India, where a pilgrim fair is held every autumn, and Brahma has the only temple dedicated to him in India.

The district of Ajmere, which forms the largest part of the province of Ajmere-Merwara, has an area of 2,125 square miles. The population in 1921 was 378,960, inclusive of Ajmere city. Besides the city of Ajmere, the district contains the military station of Nasirabad, with a population of 19,651.

AJMERE-MERWARA, a division or petty province of British India, in Rajputana, consisting of the two districts of Ajmere and Merwara, separated from each other and isolated amid Indian States. The administration is in the hands of a commissioner, subordinate to the governor-general's agent for Rajputana. The capital is Ajmere city. The area is 2,599 sq.m. The Aravalli range is the distinguishing feature of the district. The range of hills which runs between Ajmere and Nasirabad marks the watershed of the continent of India. The rain which falls on one side drains into the Chambal, and so into the Bay of Bengal; that which falls on the other side, into the Luni, which discharges itself into the Runn of Cutch. The province is on the border of what may be called the arid zone; it is the debatable land between the north-eastern and south-western monsoons, and beyond the influence of either. The south-west monsoon sweeps up the Nerbudda valley from Bombay and crossing the tableland at Neemuch gives copious supplies to Malwa, Jhalawar and Kotah and the countries which lie in the course of the Chambal river; but it is only when the monsoon is in considerable force that Merwara gets a plentiful supply from it. The north-eastern monsoon sweeps up the valley of the Ganges from the Bay of Bengal and waters the northern part of Rajputana, but hardly penetrates farther west than the longitude of Ajmere. The agriculturist in Ajmere-Merwara can thus rarely rely upon two good harvests in succession. A province subject to such conditions can hardly be free from famine or scarcity for any length of time; and the pop. in 1921 (448,078) was actually lower than it had been 30 years earlier. Among Hindus, the Rajputs are land-holders, and the Jats and Gujars are cultivators. The Jains are traders and money-lenders. The aboriginal tribe of Mers are divided between Hindus and Mohammedans. The chief crops are millet, wheat, cotton and oil-seeds. There are several factories for ginning and pressing cotton, the chief trading centres being Beawar and Kekri.

AJODHYA, an ancient city of India, situated on the right bank of the Gogra, in the Fyzabad district of the United Provinces. In remote antiquity Ajodhya was one of the largest and most magnificent of Indian cities. It is said to have covered an

area of 96 sq.m., and was the capital of the kingdom of Kosala, the court of the great king Dasaratha, who was the father of Rama, the hero of the *Ramayana*. The opening passages of that epic recount the magnificence of the city, the glories of the monarch and the virtues, wealth and loyalty of his people. A period of Buddhist supremacy followed the death of the last king of the Solar dynasty. On the revival of Brahmanism, Ajodhya was restored by King Vikramaditya (c. 57 B.C.). Kosala has claims to be the birthplace of the founders of both Buddhism and Jainism. The Chinese traveller, Hsüan Tsang, in the 7th century, found 20 Buddhist temples with 3,000 monks at Ajodhya among a large Brahmanical population. The ancient city is now represented by a heap of ruins, with a few fine temples, and the modern town is only a small suburb of Fyzabad.

AKA HILLS, a tract of country on the north-east frontier of India, occupied by an independent tribe called the Akas. It lies north of the Darrang district of eastern Bengal and Assam, and is bounded on the east by the Dafia Hills and on the west by independent Bhutia tribes. The Aka country is very difficult of access, the direct road from the plains leading along the precipitous channel of the Bhareli river, which divides the Aka from the Dafia country. The Akas are a brave people, and the men are strong and well-made. They have clans graded socially, a dual organization and burial of the dead. They worship the Bhareli river annually, poison their arrows with aconite and play both varieties of nose flute. Their reputation as raiders is sufficiently shown in the division of the tribe into two clans, the Hazari-khoas or "eaters of a thousand hearths," and the Kapah-chors or "thieves that lurk in the cotton fields." In the early years of British occupation, about 1829, they gave much trouble; and in 1883 they broke out once more into their old habits. They raided into the British district of Darrang and carried off several native forest officers as hostages. An expedition was sent against them under Gen. Sale Hill with 860 troops, which was completely successful. Living among them as a labouring but not servile class is the Niggiya or Khoa tribe divided into four clans.

See Nevill, "The Akas," *Assam Census Report*, 1921, I. App. B. i.

AKALKOT, a native State of India, in the Deccan division of Bombay, ranking as one of the Satara Jagirs, in the Sholapur agency. It forms part of the Deccan table-land, and has a cool climate. Area 498 sq.m.; pop. (1921) 81,250, a decrease of 9% in the decade, balanced by a similar increase in 1901-11. The tribute is £1,000. The State is under British management.

The town of Akalkot is situated near the Great Indian Peninsula railway, which traverses the State. Pop. (1921) 9,189.

AKAN, a Gold Coast tribe inhabiting the Koforidua district of the Accra hinterland, neighbours of the Fanti and Ashanti, with whom they probably share a common origin, their language being closely related to these two idioms, and their organization being the same.

See Sarbah, *Fanti Customary Law* (1904).

AKBAR, JELLALADIN MOHAMMED (1542-1602), the greatest and wisest of the Mogul emperors of India. He succeeded to the throne in 1556, but his position was not an enviable one. He was under the regency of Bairam Khan, a despotic Turkoman noble, until in 1560 he took the government into his own hands. The first seven years of his reign were entirely occupied by warfare; he established his authority in the Punjab and in the districts of Delhi and Agra. In 1567 he assaulted Chitor and conquered Ajmere, and three years later he obtained possession of Oudh and Gwalior. In 1572 he conquered Gujarat and made the province a Mogul viceroyalty; his generals drove the Afghans from Bengal, and six years later Orissa was annexed. By 1594 Akbar had further annexed Kabul, Kashmir, Sind and Kandahar. Having now a far greater part of India under his sway than had ever owed allegiance to one ruler, he did not rest, but attacked the Deccan, seizing Berar.

Great as he was as a conqueror, Akbar is chiefly remembered for his wonderful administrative ability. In order that taxation should be on a sound basis, he instituted accurate surveys and fought extortion. He developed commerce and invented a feudal organization, whereby tributary rajas took their places by the side

of his own Mogul nobles in military matters. He examined carefully all the religious beliefs of his varied subjects, and finally adopted for himself a pure deism which, so far from militating against individual creeds, embraced them all. He gained for himself the title "Guardian of Mankind" for his toleration and wide sympathies. A munificent patron of the arts, he established schools throughout the empire where, without discrimination, Hindus, Muslims and Parsis might study together. Abu'l Fazi (*q.v.*), one of the scholars surrounding Akbar at the court, wrote a splendid record of the emperor's reign (*Akbar Nameh*).

For the general history of his reign see *INDIA, History*; see also G. B. Mallison, *Akbar*, "Rulers of India" series (1890).

AKCHA, a town and khanate of Afghan Turkistan, 42m. W. of Balkh on the road to Andkhui. It is protected by a mud wall and a citadel. Estimated population 8,000, chiefly Uzbeks. The khanate is small, but well watered and populous. The rivers which rise in the southern mountains no longer reach the Oxus, but end near Akcha in vast swamps filled in flood time with debris of hillside plants.

AKEE, the West African name of a small tree (*Blighia sapida*) of the soapberry family (Sapindaceae), native to Guinea, and also of its important food fruit. Introduced in 1778 into Jamaica, which now exports the fruit, its cultivation has spread throughout most of tropical America. The shrub-like, stiff-branched tree, sometimes 20 ft. to 30 ft. high, bears handsome red or orange-coloured fruits, about 3 in. long, in small clusters at the tips of slender branches. The fruit, which is a soft-walled capsule, splits when ripe into three sections, from apex to base, displaying round, shining, black seeds, attached to the base by large whitish or yellowish fleshy arils. When cooked the arils bear a resemblance to a fine omelette both in taste and in appearance; the Latin-American name *seso vegetal* (vegetable brain) is significant of their form.

AKEN, a town of Germany on the Elbe in the south-east of the district of Magdeburg, Prussian Saxony. Pop. (1925) 9,493. Chemicals and oils are manufactured. There is considerable transit trade on the Elbe, and petrol storage.

AKENSIDE, MARK (1721-1770), English poet and physician, was born at Newcastle-on-Tyne. He was the son of a butcher, and was slightly lame all his life from a wound he received as a child from his father's cleaver. He was sent (1739) to Edinburgh to study theology with a view to becoming a minister, but in fact studied medicine, and seems to have drifted to a mild deism. His politics, says Dr. Johnson, were characterized by an "impetuous eagerness to subvert and confound, with very little care what shall be established," and he is caricatured in the republican doctor of Smollett's *Peregrine Pickle*. He had already acquired a considerable literary reputation when he came to London, about the end of 1743, and offered his *Pleasures of the Imagination* to Dodsley for £120. Dodsley thought the price exorbitant, and only accepted the terms after submitting the ms. to Pope, who assured him that this was "no everyday writer." The three books of this poem appeared in Jan. 1744. It was translated eventually into German, French and Italian, and gained a general success.

Akenside had taken a medical degree at Leyden and then tried to establish himself in medical practice at Hampstead. His life-long friend, Jeremiah Dyson, took a house there, and did all he could to further his friend's interest in the neighbourhood; but Akenside's arrogance and pedantry frustrated these efforts, and Dyson then took a house for him in Bloomsbury square, making him independent of his profession by an allowance which enabled him to "keep a chariot," and to live "incomparably well." In 1746 he wrote his much-praised "Hymn to the Naiads," and began to contribute to Dodsley's *Museum, or Literary and Historical Register*. He was now 25 years old and began to devote himself almost exclusively to his profession. He was an acute and learned physician. In Jan. 1759 he was appointed assistant physician, and two months later principal physician to Christ's Hospital, but he was charged with harsh treatment of the poorer patients. At the accession of George III. both Dyson and Akenside changed their political opinions, and Akenside's conversion to Tory principles

was rewarded by the appointment of physician to the queen. Dyson became secretary to the Treasury, lord of the Treasury, and in 1774 privy councillor and cofferer to the household.

Akenside died on June 23, 1770, at his house in Burlington street, where the last ten years of his life had been spent. He left all his effects and his literary remains to Dyson, who issued an edition of his *Poems* in 1772. This included the revised version of the *Pleasures of Imagination* on which the author was engaged at his death. The ideas embodied in this work were largely borrowed from Addison's essays on the imagination and from Lord Shaftesbury. Professor Dowden complains that "his tone is too high-pitched; his ideas are too much in the air; they do not nourish themselves in the common heart, the common life of man." Dr. Johnson praised the blank verse of the poems, but found fault with the long and complicated periods. The odes are dignified and often musical, while the few "inscriptions" are felicitous in the extreme.

See Dyce's *Life of Akenside* prefixed to his edition of the *Poetical Works* (1835); also Johnson's *Lives of the Poets*, and C. Bucke, *Life Writings and Genius of Akenside* (1832).

AKHALTSIKH, a town in the Georgian S.S.R. It is situated in 41° 40' N. and 42° 55' E. at an altitude of 3,375 ft. on a tributary of the Kura river. The new town is on the right bank, the old on the left. Pop. (1926) about 15,000. It was the capital of Turkish Armenia from 1579 until it was captured by the Russians in 1828. There is trade in silk, honey and wax. Brown coal is found in the district. Its silver filigree work is famous. It is on the trade route to Turkey for caravans, but it has no railway communications.

AKHENATEN: see IKHNATUN.

AK-HISSAR (anc. THYATEIRA, the "town of Thya"), a town situated in a fertile plain on the Gürdük Çai (Lycus), in the Sarnkhan vilayet, 58m. N.E. of Smyrna. Pop. (1927), 47,716. Thyateira was an ancient town re-peopled with Macedonians by Seleucus about 290 B.C. It became an important station on the Roman road from Pergamum to Laodicea, and one of the "Seven Churches" of Asia (Rev. ii. 18), but was never a *metropolis* or honoured with a neocorate, though made the centre of a *conventus* by Caracalla. The modern town is connected with Smyrna by railway, and exports cotton, wool, opium, cocoons and cereals. Cotton of excellent quality is grown in the neighbourhood, and the place is celebrated for its scarlet dyes.

See W. M. Ramsay, *Letters to the Seven Churches* (1904); M. Clerc, *De rebus Thyatirensium* (1893).

AKHMIM, a town of Upper Egypt, on the right bank of the Nile, 67m. by river south of Asyut, and 4m. above Suhag, on the opposite side of the river. It has several mosques and two Coptic churches, maintains a weekly market, and manufactures cotton goods, notably the blue shirts and check shawls with silk fringes worn by the poorer classes of Egypt. Outside the walls are the scanty ruins of two ancient temples. In Abulfeda's days (13th century A.D.) a very imposing temple still stood here. Akhmim was the Egyptian Apu or Khen-min, in Coptic Shmin, known to the Greeks as Chemmis or Panopolis, capital of the 9th or Chemmite nome of Upper Egypt. Herodotus mentions the temple dedicated to "Perseus" and asserts that Chemmis was remarkable for the celebration of games in honour of that hero, after the manner of the Greeks, at which prizes were given; but it is possible that he confused Coptos (*q.v.*) with Chemmis. Strabo mentions linen-weaving as an ancient industry of Panopolis, and it is not altogether a coincidence that the cemetery of Akhmim is one of the chief sources of the beautiful textiles of Roman and Coptic age that are brought from Egypt. Monasteries abounded in this neighbourhood from a very early date. Nonnus, the Greek poet, was born at Panopolis.

AKHTAL (ahčh-tahl') (GHIVATH IBN HARITH) (c. 640-710), Arabian poet of the Omayyad period, belonged to the tribe of Taghlīb in Mesopotamia, and was, like his fellow tribesmen, a Christian, enjoying the freedom of his religion, while not taking its duty very seriously. Akhtal, Jarir and Ferazdaq form a trio celebrated among the Arabs, but as to relative superiority there is dispute. Abu 'Ubaida placed him highest of the three on

the ground that amongst his poems there were ten flawless *qasidas* ("elegies"), and ten more which were nearly so, and that this could not be said of the other two poets.

See *Diwan de Aḥṭal* *Reproduction photolithographique du manuscrit de Bagdad, avec préface et variantes* par le P. A. Salhani (Beirut, 1905); *Le Diwān d'al-Aḥṭal reproduit par la photolithographie s'après un manuscrit trouvé au Yémen, avec préface, glossaires . . .* par le Dr. Eugenio Griffini (Beirut, 1907). A full account of the poet and his times is given in H. Lammens' *Le chantre des Omiades* (Paris, 1895) (a reprint from the *Journal Asiatique* for 1894).

AKHTYRKA, a town in the Ukrainian S.S.R. It is situated in 50° 20' N. and 34° 52' E. near the Vorskla river, on the railway from Kiev to Kharkov. Its beautiful cathedral, built in 1753, was designed by Rastrelli. It is a trade centre for fruit, sugar-beet, corn, cattle and domestic woollen industries. It was founded by Poles in 1642. Pop. (1926) 30,000.

AKKA (ṬIKKI-ṬIKKI), a race of African pygmies first seen by the traveller G. A. Schweinfurth in 1870, in the Mangbettu country, north-west of Albert Nyanza. The home of the Akka is the dense forest zone of the Aruwimi district of the Congo State. They form a branch of the primitive pygmy negroid race, and appear to be divided into groups, each with its own chief. The average height of the race would seem to be somewhat under 4ft. They are of the colour of coffee slightly roasted, with hair almost the same colour, woolly and tufted; they have very projecting jaws, flat noses and protruding lips. An abdominal protuberance makes all Akka look like pot-bellied children, and the spine hollows into a curve like an S. These characteristics tend to disappear. There is a tendency to steatopygia among the women. They are nomads, hunt game in the forests with poisoned arrows, with pitfalls and springs set everywhere, and with traps. They collect ivory and honey, manufacture poison, and exchange these for cereals, tobacco and iron weapons. In dress, weapons and utensils they are as the surrounding negroes. They build round huts of branches and leaves in the forest clearings.

BIBLIOGRAPHY.—A. de Quatrefages, *The Pygmies* (1895); G. A. Schweinfurth, *Heart of Africa* (London, 1873); Dr. W. Pleyte, *Chapitres supplémentaires du Livre des Morts, traduction et commentaire* (Leiden, 1883); Sir H. H. Johnston, *Uganda Protectorate* (London, 1902).

AKKAD (the country, for the town sometimes called Akkad; see under AGADE), northern Babylonia. The alluvial part of Mesopotamia was known in ancient times as Sumer and Akkad. Akkad was the narrow strip of land where the rivers approached one another most closely, and included the cities of Opis, Kish, Babylon, Sippar, Borsippa and Cutha. For details see MESOPOTAMIA: *Ancient Geography*, and under the cities named.

AKKADIAN: see ACCADIAN.

AKKERMAN, a town in Rumania (see CETATEA ALBA).

AKMOLINSK, a province of Kazak (Kirghiz) A.S.S.R. The boundaries are, north, the Ural area; east, Semipalatinsk; south, Syr Daria; west, Aktyubin and Kustanai provinces. Area 243,990 sq.km. Pop. (1926) 287,641; urban 12,770, rural and nomad 274,871. In the north the province is dotted with salt lakes, sloping south to a plateau (1,600ft.), to the east of which is a spur formed by the dying out of the Tarbagatai range containing gold, copper and coal. The Spassky copper mines are in the province and were re-started in 1925; near them are the Karagandinask coal beds, estimated at 6,000 million tons; the two are connected by rail, but are not yet linked to the main railway (1927). When this is done, the area will probably develop into an industrial centre. The south-east is a wide, waterless desert, the Bak-pak-dala or Hunger steppe. The climate is dry and continental, the rainfall (average 8–16in.) is mostly in heavy thunderstorms, moistening the surface only. Dry, strong north-east winds, dusty in summer, prevail all the year, in winter as the Buran gale, sweeping the snow away and exposing the ground to five months of frost. At Akmolinsk city (average temperature January 1.5° F., July 70° F.; yearly rainfall gin.), south of latitude 50°, the steppe is salty soil, with sparse wormwood, blue grey grass, and plants with drought-resisting devices, hairs, pungent oils, thick leaves, etc., and animals such as suslik, hamster, jerboa and, rarely, saiga antelope. North of latitude 50° there is more

moisture and better soil; in spring it is gay with tulips, irises, etc.; and in summer with white feather grass. The southern part of this area is inhabited by Kirghiz (in the Chu valley). The nomad Kara Kirghiz rear sheep, horses, camels, cattle and goats, following the pasture. Near the northern boundary of the province, wheat and barley are successfully grown, and the population consists mainly of Russian peasants. Petropavlovsk (q.v.) is the chief administrative centre, on the Ishym river. The town of Akmolinsk, on the Ishym river, is on the caravan routes from Tashkent and Bukhara to the north.

AKOLA, a town and district of India, in Berar, otherwise known as the Hyderabad Assigned Districts. The town is on the Murna tributary of the Purna river, Akola proper being on the west bank, and Tajnapeth, containing the Government buildings and European residences, on the east bank. It had a pop. (1921) of 37,864. It is walled, and has a citadel built in the early years of the 19th century. Akola is one of the chief centres of the cotton trade in Berar, and has numerous ginning factories and cotton presses. Among the educational establishments are a Government high school, and an industrial school supported by a Protestant mission.

The District of Akola as reconstituted in 1905 has an area of 4,110sq.m., the population of this area in 1921 being 798,544. The surface of the country is generally flat, the greater part being situated in the central valley of Berar. On the north it is bounded by the Melghat hills. By the addition of Basim and Mangrul *taluks* in 1905, the district includes the eastern part of the Ajanta hills, with peaks rising to 2,000ft., and the tableland of Basim. North of the Ajanta hills the country is drained eastward by the Purna affluent of the Tapti and its tributaries. The average temperature at the town of Akola in May for the 25 years ending 1901 was 94.4° F. But even during the hot season the nights are cool. The annual rainfall averages 34in. In the Purna valley the soil is everywhere a rich black loam particularly suitable to cotton, and nearly the whole of the land is cultivated. The history of Akola is not distinguished from that of the other portions of Berar.

AKRON, a city of Ohio, U.S.A., 35m. S.-by-E. of Cleveland, on the Little Cuyahoga river; the county seat of Summit county. It is about 1,000ft. above sea-level, on one of the highest spots in the State, whence its Greek name. The surrounding country is hilly and there are 20 lakes within 12m. of the city. On its northern boundary the Big Cuyahoga river flows through a gorge of great beauty, spanned by High Level bridge. The main approach from the north and east is by the North Hill viaduct, 135ft. high and 2,800ft. in length. Akron is served by the Baltimore and Ohio, the Erie, the Pennsylvania, and the Akron, Canton and Youngstown railways. A belt line encircles the industrial section. A municipal airport is projected. The Ohio canal, abandoned by commercial traffic, supplies water to some of the industries from lakes south of the city, and serves as a pleasure route to the Portage Lake State park near by. The city covers 25.3 sq. miles. Its population in 1920 was 208,435, of whom 5,580 were negroes and 38,021 foreign born; in 1926 a local census gave the population as 209,572; in 1930 the Federal census gave 255,040.

The important period in Akron's history began about 1910. The town had been settled about 1825 and incorporated as a village in 1836; had become the county seat in 1842, and had been chartered as a city in 1865. Through the 19th century it had a normal gradual development, due at first to its position on the Ohio canal, later to the completion of the railway which is now the Erie, and still later to the manufacture of clay products and rolled oats. The pioneer rubber factory was established by Dr. B. F. Goodrich in 1869, and others came into existence with the extension of the uses of rubber for bicycle tyres, heels and soles, beltings for machinery, elastic stockings, insulated wire and many other purposes. By 1900 the population had increased to 42,728, and in 1910 it was 69,067.

Then began a phenomenal growth. Between 1910 and 1920 the population of the city tripled. The aggregate value of its manufactured products rose from \$73,158,000 in 1909 to \$558,962,000 in 1919; the average number of wage-earners in the factories

increased from 15,831 to 65,054. Postal receipts were quadrupled. All this was due chiefly to the demand for tires and other rubber products by the automobile industry. Akron's 20 rubber factories have 500 ac. floor area and produce 30,000 articles, ranging from rubber bands to balloons and dirigibles, and including a daily output of 125,000 automobile tyres. They use about half of all the crude rubber imported into the United States, or nearly 40% of all produced in the world.

The older industries (oatmeal, matches and sewer-pipes) are still important. The town produces also puffed grains for breakfast foods, chemical stoneware, porcelain insulators, toy marbles and porcelain moulds for rubber articles. During the World War more than 1,000 air-craft were built by Akron companies, and the city is a centre for the production of the lighter-than-air variety. Fishing tackle, rubber-factory equipment, steel automobile rims, sewer-pipe and well-drilling machinery are other characteristic products. Salt and sulphur are refined, and zinc oxide is produced.

The abnormal growth was arrested by the general business depression of 1920-21, but by 1923 recovery was well under way. In 1927 the value of the factory products (\$567,482,407) exceeded the high figure of 1919.

The rapid industrial development stimulated progress in other directions. Expenditures by the city for health and sanitation increased from \$53,231 in 1910 to \$444,865 in 1925; for education from \$277,454 to \$2,744,150. A municipal water system and a sewage-treatment plant were provided at a cost of \$14,750,000, and an imposing municipal building was erected. Experts surveyed the public school system (1917) and prepared a city plan (1919). A city planning commission created in 1920 secured the adoption of a zoning ordinance in 1922. A large park and municipal golf links were presented to the city in 1924, bringing the total area in its 26 parks to 475 acres. From 1920 the charitable agencies were jointly financed by a "community chest" operated by the Better Akron Federation.

The University of Akron, which is a part of the free public-school system of the city, was created in 1913, when the city council accepted, as a nucleus, the plant and endowment of Buchtel college, which had been founded in 1870 and named after its chief benefactor, John R. Buchtel (1822-92), a business man of Akron. Fellowships for research in the chemistry of india-rubber have been established by the Goodyear and the Firestone Tire and Rubber Companies. In 1926-27 the enrolment in the university was about 2,000.

Because of the dominating industries Akron's population has a striking preponderance of men (138.9 males to 100 females in 1920, a higher ratio than in any other large city); a high proportion of skilled and semi-skilled labour; relatively high wages; and a high proportion of men engaged in gainful occupations. Of child labour and illiteracy there is little. The population was not congested, even after the period of rapid growth. Small detached or semi-detached dwellings are the rule. In 1920 45% of the homes were owned by their occupants.

A "home rule" charter went into effect Jan. 1 1920. Under it Akron adopted the city-manager form of government, but after four years this was discarded and the executive duties were transferred to a mayor elected at large. The old Portage Trail, used by the Indians in carrying their canoes from the Cuyahoga river to the Tuscarawas river in the journey from Lake Erie to the Ohio, runs through the city. It is marked at each end by commemorative tablets and bronze figures of Indians. A house once occupied by John Brown, the abolitionist, still stands in the western part of the city.

AKSAKOV, SERGEI TIMOFEYEVICH (1791-1859), Russian writer, grandson of Sergei Aksakov, a country squire who founded a colony in the Bashkir steppe, was born at Ufa, Orenburg, on Sept. 20, 1791, and died in Moscow on April 30, 1859. He studied at the University of Kazan, and in 1808 entered the civil service in St. Petersburg (Leningrad). In 1815 he married and returned to the Urals to cultivate his estate. He dissipated his fortune after ten years of estate management, and found, through the influence of Shishkov, a place in the censorship at Moscow. There his house became a centre of Slavophil-

ism. In 1832 he met Gogol, in whom he recognized a genius unspoiled, as he thought, by foreign influence. His friendship with Gogol led him to write himself, and, though that friendship was clouded in later years, it is to Gogol that Aksakov owed his inspiration. Aksakov draws on the history of his pioneer grandfather, a great figure of the family autocrat in a primitive community, wonderfully depicted, with the marriage of his own father and mother, and with his own schooldays. All these books are Russian classics. They give a picture of Russian rural life before the liberation of the Serfs remarkable in itself, and beautiful because of the author's keen, sensuous appreciation of nature, but interesting from the purely literary point of view in the development of the novel. Aksakov, to quote Prince Mirsky, "came nearer than any other Russian writer, even than Tolstoy in *War and Peace*, to a modern, evolutionary, continuous presentation of human life, as distinct from the dramatic and incidental presentation customary to the older novelists."

His best known works are: *Chronicles of a Russian Family* (1856, trans. by M. C. Beverley, 1924); *Recollections* (1856), trans. by J. D. Duff under the title: *Autobiography of a Russian Schoolboy* (1917, repr. 1924); *Years of Childhood* (1858; trans. by J. D. Duff, 1916, repr. 1923). Aksakov's other important work is his *Recollections of Gogol*, which is the most important contemporary record of that great writer.

His elder son, KONSTANTIN SERGEYEVICH AKSAKOV (1817-1860), Slavophil author, was born at Moscow on April 10, 1817, and died in the Island of Zante in Greece on Dec. 19, 1860.

His younger son, IVAN SERGEYEVICH AKSAKOV (1823-1886), Russian Slavophil writer, was born at Nadezhdin in Ufa, on Sept. 26, 1823, and died at Moscow on Jan. 27, 1886. He studied law at St. Petersburg, and later entered the Moscow division of the Senate. At various periods he edited or established weekly and daily papers, the Moscow *Sbornik*, the *Den* (1861-65), the *Moskva* (1867), which was three times suppressed by the Government, and later, in 1880, the *Rus*, an organ of the Slavophil party. Between 1840 and 1860 Aksakov wrote numerous radical and political poems. His realistic poem *The Tramp* (1852), depicted the life of the Russian peasant. The height of Aksakov's activity as leader of the Panslavist movement was reached in 1876-78, when he warmly supported the cause of the liberation of the Balkan Slavs. In 1878 he was exiled from Moscow for a violent attack on the Treaty of Berlin in a speech delivered at the Slavic committee; but he was soon allowed to return, and continued to publish the *Rus* until his death.

AKSHAK, a city in northern Sumer in lat. 34° N., long. 44° E. There was a prehistoric Sumerian city on this site which lay on the Tigris at the mouth of the river Adhem (Physcus). It was the most northerly of the Sumerian cities and appears in the dynasty lists between Maer and the 4th dynasty of Kish. The site is usually identified with the Opis of Xenophon, who states that it was a large and populous city and that the Physcus was here spanned by a bridge, but Rawlinson identified Opis with another ancient site south of the Diyala, near Baghdad.

AK-SHEHR (anc. PHILOMELION), town, Konia vilayet, Asia Minor, at the edge of a fertile plain, on the north side of the Sultan Dag. Philomelion was probably a Pergamenian foundation on the Graeco-Roman highway from Ephesus to the east, and to its townsmen the Smyrniotes wrote the letter that describes the martyrdom of Polycarp. Cicero, on his way to Cilicia, dated some of his extant correspondence there; and the place was important in frontier wars between Byzantine emperors and the sultanate of Rum. It became an important Seljuk town, and late in the 14th century passed into Ottoman hands. There Bayezid Yilderim is said by Ali of Yezd to have died after his defeat at Angora. The place still enjoys much repute among Turks as the burial place of Nasr-ed-din Hodja. The town has a station on the Anatolian railway, about 60 m. from Afium Qarahisar and 100 m. from Konia. Pop. (in 1927), 46,057.

AKSU: see TURKISTAN.

AKSUM (previously AXUM), an ancient city in Tigré, Abyssinia, 14° 8' N., 38° 31' E., altitude 7,226 ft., 12 m. W. by S. of Aduwa. The old Abyssinian Book of Aksum contains the native legend of its foundation many thousands of years ago; the first

authoritative mention of it, however, is in the *Periplus Maris Erythraei* (c. A.D. 67) where it is referred to as the seat of the Axumite Kingdom, the successor of the more ancient Punt and the forerunner of the modern Abyssinia. (See ETHIOPIA.)

It contains the ancient church where, according to tradition, the *Tobot* or Ark of the Covenant, brought from Jerusalem by the son of Solomon and the Queen of Sheba, was deposited and is still supposed to rest. The church was burned when Axum was sacked by Mohammed Gran the Muslim invader of Abyssinia in about 1535 and a new one was erected by the Portuguese shortly afterwards. It is famous for the ancient inscriptions in Minaco Sabaeen, a Giz script of the 4th and 5th centuries and for its wonderful stone obelisks, many of which are still standing. They form a consecutive series from rude unhewn stones to highly finished obelisks, of which the tallest still erect is 60ft. in height, with 8ft. 7in. extreme front width; others that are fallen may have been taller. The highly finished monoliths are all representations of a many-storeyed castle, with an altar at the base of each. They appear to be connected with Semitic sun-worship and are assigned by Bent to the same period as the temple at Baalbek.

BIBLIOGRAPHY.—Classical references, Pietschmann in Pauly's *Realencyklopädie* (2nd ed.); History from inscriptions, see D. H. Müller, Appendix to J. T. Wyld, *Modern Abyssinia* (1901).

AKTUBINSK, formerly part of the Turgai region, now a province in the Autonomous Kazak (Kirghiz) S.S.R. Area 457,479sq.km. The boundaries are, on the north, Orenburg and Kustanai; west, Adaev and Uralsk; south, Adaev, the Aral sea and Syr-Daria; east, Akmolinsk. It is divided for administrative purposes into Aktubinsk, pop. 238,059 (urban 20,504); Temirsk, pop. 77,799 (urban 4,000); Turgai, pop. 94,304 (urban 1,836); Chelkarsk, pop. 90,376 (urban 6,716). South of the east to west stretch of the Ural river, the Ural mountains continue as a plateau, the southward termination of which (the Mugojar hills) is deeply dissected by the streams of the craggy south-eastern slopes, a former shore line of the Aral sea. Beneath these slopes the streams lose themselves in the saline steppes that fringe the Aral sea and extend far northeast as part of the Turgai steppe. The climatic conditions are increasingly dry (av. rainfall 4 to 8in.), and the prevailing north-east winds bring sandstorms in summer and dry snow in winter, a season otherwise of cloudless skies and bitter cold, while the summer temperature averages 85° F. The numerous lakes are surrounded by reeds, the haunt of the wild boar, with grass patches in places; the stream shores are also grassy, especially in spring, and attract geese and cranes. The steppe includes black-earth areas carrying feather grass, clays bearing wormwood, salt clays with salsolaceae vegetation and bare shifting sand hills. Wild cherry and almond grow on the hill sides. The steppe fauna includes jerboa, marmot, steppe fox and saiga antelope. Famines are frequent for lack of irrigation and scientific crop rotation, though rye, wheat, oats, barley and potatoes are grown. Nomadic herding of sheep, horses, camels and cattle is the chief occupation, and there is change of ground between the spring-and-summer grazing area of the Turgai steppe and the winter shelters in the Syr-Daria area. Cattle and hides are exported to Orenburg and camels are bred for the caravan transport between Bukhara, Khiva and Russian Turkistan. Sunflowerseed oil, flour and leather are produced for local use and salt is obtained from the lakes, while *koustar* (home) industries in felt products and carpets are widespread. The Emba river naphtha area extends into the south-west of the province and has its centre at Emba. In the north-west, near the Ulek river coal is mined. Aktubinsk, the chief town, is on the Orenburg-Tashkent railway.

AKYAB, a municipality and district in the Arakan division of Burma at the confluence of the large rivers Myu, Kaladan and Lemro. After the cession of Arakan to the British by the treaty of Yandaboo in 1826 the old capital of Myohaung was abandoned as the seat of government, and Akyab on the sea coast selected instead. Trade restrictions were removed and Akyab rapidly grew from a small fishing village into a leading port of Burma, with a

population in 1921 of 36,569 (27,693 males and 8,876 females). The population has varied but slightly since the census of 1881. Out of the total population, 13,132 (13,062 males and 70 females) are "adventitious" Mohammedan and Hindu labourers. The settled civil population comprises 12,149 Buddhists (Arakanese and Burmese, 5,891 males and 6,258 females), 4,755 Hindus (4,353 males and 402 females) and 5,709 Mohammedans (3,860 males and 1,849 females).

It contains the usual public buildings and several large rice mills. The chief export is rice. The district lies along the north-eastern shores of the Bay of Bengal, with an area of 5,136sq.m. and a population in 1921 of 576,430. (See BURMA.)

ALA, one of the side recesses which almost universally opened off the atrium (*q.v.*) of a Roman house. There were usually two alae, one on each side, placed near the corners furthest from the entrance, and like the *tablinum* or official reception hall, their entire width was open to the atrium. In physiology, any wing-like process such as one of the lateral cartilages of the nose (Lat. *ala*, a wing). In botany, one of the side petals of a papilionaceous corolla, etc.

ALABAMA, called the "Cotton State" because of its chief agricultural product, a southern state of the U.S.A., is situated between 84° 51' and 88° 31' W. and about 30° 13' and 35° N., and is bounded N. by Tennessee, E. by Georgia, S. by Florida and the Gulf of Mexico, and W. by Mississippi. Its total area is 51,998 sq. m., of which 719 are water surface.

Physical Features.—Northern Alabama is dominated by the Cumberland plateau, a diversified region varying from 400 to 1,800ft. in height and cut into blocks by the tributaries of the Tennessee river, which flows from east to west. In the north-east section of this region are precipitous mountains, while gentle rolling lowlands predominate in the west along the river. In the southern portion Little mountain, extending 80m. east and west between two valleys, rises 500ft. above them. To the south-east of the Cumberland plateau the Appalachian ("Coosa") valley region, occupying about 8,000sq.m. and running north-east and south-west forms the southern extremity of the Appalachian mountain system. Raccoon and Lookout are the most prominent flat-topped mountains in this limestone formation, being about 1,800ft. high at the Georgia border and lower to the south. South-east of the Appalachian valley region the gently undulating Piedmont plateau enters Alabama for a short distance. The remainder of the state is occupied by the coastal plain, which is crossed in the north by foot-hills and gradually

THE GREAT SEAL OF THE STATE OF ALABAMA, ADOPTED BY ACT OF THE GENERAL ASSEMBLY AND APPROVED ON DEC. 29, 1868

was formed by the drowning of the lower part of the valleys of the Alabama and the Tombigbee rivers.

Climate and Soil.—Alabama has a temperate, uniform climate. The annual mean for the state is for the winter 46° and for the summer 79°. In the summer the temperature is kept moderate by the elevation in the northern districts and by winds from the Gulf of Mexico in the southern part. In the winter, on the average, 35 days are below the freezing point, and snow falls only once or twice a year. Rainfall is evenly distributed throughout the state, the average being rather high, 52in. Heavy fogs are rare, hail-storms few and innocuous, thunder-storms numerous in summer. The prevailing winds are from the south.

slopes down to sea level in the south, with all rivers flowing south-west. Its rivers are the Tombigbee in the west, the Alabama in the central west, and in the east the Chattahoochee, which forms almost half of the Georgia boundary. The Tombigbee and the Alabama unite in the south-west; their waters then part to flow into Mobile bay as the Mobile and Tensas rivers. The valleys of the coastal plain are broad and in most cases rise in three successive terraces above the streams. The harbour of Mobile

There are four different belts of soil. In the timber belt, along the coast, the soil is sandy and poor but responds to fertilization. North of this lies the black belt ("black prairie," "cotton belt"), which is 13,000sq.m. in extent and has black soil that is rich in limestone and marl formations, without sand or loam, and is especially adapted to the production of cotton. Between the cotton belt and the Tennessee valley lies the mineral belt, the soils of which are of varied fertility. North of the mineral belt is the cereal belt in the Tennessee valley, containing red clays and dark loams. North of the valley the soils are not so fertile.

Government.—The form of government in Alabama has been altered five times. The original constitution was set up in 1819

THE STATE CAPITOL AT MONTGOMERY, ALABAMA

The capitol was the scene of important activities in the Civil War period. In its chambers was effected the organization of the Confederate States, and the president of the Confederacy took the oath of office on the front portico

and revised in 1865, 1868, and 1875; the present constitution was framed in 1901 and contains a number of notable provisions. It lengthened the term of executive and legislative officials from two to four years, made that of the judiciary six years, provided for quadrennial sessions of the legislature, and introduced the office of lieutenant-governor. The passage of local or special bills by the legislature was prohibited. A provision, intended to prevent lobbying, prohibits anyone except legislators and the representatives of the Press to be admitted to the floor of the house except by unanimous vote. No executive official may serve two consecutive terms in office, and the governor cannot be elected or appointed to the United States Senate or to any state office during his term as governor or within one year thereafter. Sheriffs whose prisoners suffer mob violence may be impeached. The constitution eliminated the negro from politics by a suffrage clause which came into effect in 1903. This restricts the right to vote to those who can read and write any article of the constitution of the United States, and have worked or been regularly engaged in some lawful employment, business or occupation, trade or calling for the greater part of the 12 months preceding the time they offer to register, unless prevented by physical disability from labour or ability to read and write, or who have paid taxes on property assessed at \$300; but those who have served in the army or navy of the United States or of the Confederate States in time of war, their lawful descendants in every degree, and persons of good character "who understand the duties and obligations of citizenship under a republican form of government," are relieved from the operation of this law provided they registered prior to Dec. 20, 1902. The second of these exceptions is known as the "grandfather clause." No man may vote in any election who has not by Feb. 1 preceding that election paid all poll-taxes due from him to the state. In 1902, nine-tenths of the negroes in the state were disqualified from voting. The constitution of 1901 (like that of 1867) and special statutes require separate schools for white and negro children. A "Jim Crow" law was enacted in 1891. Buying, selling, or offering to buy or sell a vote has for penalty disfranchisement, and since 1891 the Australian ballot system has been used (*see* ELECTORAL SYSTEMS). The governor, auditor, and attorney-general are required to prepare and present to each legislature a general revenue bill; and the secretary of state and the two last named officers form a board of pardons which makes recommendations to the governor; he, how-

ever, is not bound by this advice in the exercise of his pardoning power. The constitution of 1901 exempted a homestead of 80 acres of farm land, or of a house and lot not exceeding \$2,000 in value, from liability for any debt contracted since July 30, 1868, except for a mortgage on it to which the wife consented; personal property to the value of \$1,000 is exempted. All amendments to the state constitution must be approved by a three-fifths vote of each house of the legislature and then ratified by the people. Under the civil code of 1897 the earnings of a wife are her separate property, and it is provided that "no woman, nor any boy under the age of 12 years, shall be employed to work or labour in or about any mine in this state." By acts of 1915 and 1919 restrictions were placed upon the employment of children. No child under 14 may be employed during school hours; no child under 14 may be employed in gainful occupations except agriculture and domestic service. No child under 16 may be employed on or near dangerous machinery; except in agriculture or domestic service, no child under 16 may be employed at night or over eight hours a day or six days a week. A firm that employs a child under 16 must furnish a certificate stating what work the child is to do, a statement from the superintendent of schools to show that the child has completed the fourth grade, and a certificate showing that the child is over 14 and in good physical condition. Any person or firm violating these restrictions may be fined \$10 to \$100 for the first offence and \$100 to \$500 for each subsequent offence. Alabama, however, leads all the other states of the Union in the number of children between 10 and 13 "gainfully occupied." According to the United States census of 1920 there were 47,596 children from 10 to 13 employed in the state; of these, 45,729 were employed in agriculture, forestry, and animal husbandry.

Population.—The first census of Alabama was in 1820, when the number of inhabitants was 127,901. The number was 771,623 in 1850; 1,262,505 in 1880; 1,513,401 in 1890; 1,828,697 in 1900; 2,138,093 in 1910; and 2,348,174 in 1920. The United States cen-

GRAPH OF THE POPULATION INCREASE IN ALABAMA FROM 1820-1920

*The enumeration of 1870 was "generally deficient" in the Southern States

sus gave 2,646,248 in 1930. Alabama is noted for its large proportion of negroes (38.4% in 1920) and its small proportion of foreigners (less than 1%). In 1920, there were 1,447,032 whites, an increase of 17.8% over 1910, and 900,652 negroes, a decrease of 0.8% from 1910, due to male negro migration to northern industrial centres. The negro population is unevenly distributed; in most of the counties of the black belt the negroes constitute over 75% of the population, whereas in the northern counties they are few in number. Although the proportion of urban population in 1920 was greater than in 1910, more than three-fourths of the population was still rural (1,838,857) and over one-half

lived on farms (1,335,885). In 1925 the number of people living on farms had decreased still further to 1,166,432. In church membership, Baptists and Methodists lead. The growth of the chief cities is shown in the following table:—

	1930	1920	1910
Birmingham . . .	259,678	178,806	132,685
Mobile . . .	68,202	60,777	51,521
Montgomery . . .	66,079	43,464	38,136
Gadsden . . .	24,042	14,737	10,557
Anniston . . .	22,345	17,734	12,794
Bessemer . . .	20,721	18,674	10,864
Tuscaloosa . . .	20,659	11,996	8,407
Selma . . .	18,012	15,589	13,649

Finance and Taxation.—One-half of the income of the state is derived from general taxes, the rest from licences, a special school tax, a poll-tax, and tonnage taxes in minerals. The state has neither inheritance nor income taxes; the constitution of 1901 limits the state property tax to 0.65% upon assessed values. Both real and personal property valuations for taxing purposes are fixed by law at 60% of a reasonable cash value. The framers of the constitution of 1901, thinking to avoid a repetition of the reckless borrowing of the reconstruction period, prohibited the increase of the state debt for any other purposes than the suppression of rebellion or resistance to invasion; but in 1922 two constitutional amendments authorized the state legislature to provide bond issues of \$25,000,000 and \$10,000,000 for highway and harbour improvements.

Education.—Public education, authorized for Mobile alone in 1826 and inaugurated there in 1852, was extended to the whole state in 1854. Its support was derived from public lands given to the state by the United States in 1819 and from special taxes fixed by each township. This system was demoralized by the Civil War; the one that replaced it in 1868 failed because of the attempt to teach whites and blacks in the same schools and because of corruption in the use of school funds. The constitution of 1875 made the support of the schools dependent upon the land grant of 1819, the poll-tax, and state appropriations; it established separate schools for blacks and whites. The constitution of 1901 makes obligatory a state tax of from 30 to 65 cents on each 100 dollars' worth of property to be expended on education. The legislature of 1907 voted an increase of \$300,000 for the common school fund, granted state aid for the rural schools, and established a system of county high schools. Most of the counties have availed themselves of the privilege of levying a special school tax, granted by constitutional amendment. The expenditure for education has constantly increased until it amounted to \$14,540,233 in 1923-24, of which \$13,118,249 was used for schools for whites, and \$1,421,984 for schools for negroes. Slow but steady progress in education is signified by the decrease in illiteracy, the percentage of illiterates declining from 50 in 1880 to 34 in 1900, and to 11.4 in 1920. Of the 278,082 illiterates in 1920, the negroes numbered 216,690, the native whites 65,394, and the foreign-born whites 1,893.

The present school code of Alabama was framed in 1919 as a result of the report by the U.S. Bureau of Education at the invitation of a state educational commission. One of the most important acts provided for a state council to co-ordinate the efforts of the institutions of higher education by assigning to each a special field of activity.

Elementary education is free between the ages of 6 and 21, and compulsory between the ages of 8 and 16, except for those who have completed the elementary school course and are lawfully employed, and those who live 2½ m. or more away from a public school and are not furnished transportation. In the school

year of 1924-25 the state had in the elementary schools 857,225 pupils and 14,911 teachers.

The chief institutions for higher education include the University of Alabama, at Tuscaloosa; the Alabama polytechnic institute, at Auburn; Alabama college, at Montevallo; Athens college (Methodist, for women), at Athens; Birmingham-Southern college (Methodist), at Birmingham; Howard college (Baptist), at Birmingham; Judson college (Baptist), at Marion; Spring Hill college (Roman Catholic), at Spring Hill; St. Bernard college (Roman Catholic), at St. Bernard; Woman's college of Alabama (Methodist), at Montgomery; Talladega college (Congregationalist, for negroes), at Talladega; Tuskegee normal and industrial institute for negroes, at Tuskegee (*q.v.*); agricultural and mechanical institute for negroes, at Normal; and the state normal schools at Daphne, Florence, Jacksonville, Livingston, Troy, and, for negroes, at Montgomery.

Charities and Houses of Correction.—Alabama supports various philanthropic and penal institutions: a home for Confederate veterans, at Mountain Creek; an institution for the deaf, an academy for the blind, and a school for the negro deaf, dumb and blind, all at Talladega; a hospital for the insane, opened in 1860, at Tuscaloosa; a penitentiary, established in 1839, at Wetumpka; a state industrial school for white boys, at East Lake (Birmingham); a state industrial school for white girls, at Montevallo; a child welfare department; a reform school for negroes; and a reform school for juvenile lawbreakers. These institutions are managed by trustees who are appointed by the governor. The convict lease system was abolished by the state legislature in 1927. Able-bodied convicts are now employed by the state in highway construction—all others are put to work in a variety of industries in the state prisons at Wetumpka, Speigner, and Montgomery. In 1901, a system of peonage that had grown up in the state attracted wide attention, and a Federal grand jury at a single term of court indicted a number of men for holding persons as peons. Many similar cases were found later in other southern states, but those in Alabama, being the first discovered, attracted the most attention. The system came into existence in isolated communities through the connivance of justices of the peace with white farmers. The justices have jurisdiction over petty offences, of which negroes are usually the guilty parties, and the fine imposed would sometimes be paid by a white farmer, who would thus save the accused from imprisonment, but at the same time would require him to sign a contract to repay by his labour the sum advanced. By various devices the labourer would then be kept constantly in debt to his employer and be held in involuntary servitude for an indefinite time. The peons as a rule were negroes, but a few white ones were found; and in several instances negroes were found holding members of their own race in peonage. A law forbidding under severe penalties a labourer from hiring himself to a second employer without giving notice of a prior contract, and an employer from hiring a labourer known by him to be bound by such a contract, had aided in the development of the system, though it had been enacted for a different purpose. The Federal authorities, as soon as the existence of peonage became known, took active measures to stamp it out, and were supported by the Press and by the leading citizens of the state. Up to 1907 the state licensed the sale of liquor, and liquor licence fees were partly turned over to the public school fund; there was a dispensary system in some counties; and in 1907 one-third of the counties of the state (22 out of 67) were dry. In February of that year the Sherrod anti-shipment bill was enacted, forbidding the acceptance of liquors for shipment, transportation, or delivery to prohibition districts, and penalizing the soliciting of orders for liquor in dry districts with a punishment of \$500 fine and six months' imprisonment with hard labour. In a special session of the legislature in Nov. 1907 a law was passed forbidding the sale of liquor within the state, this prohibition becoming effective on Jan. 1, 1909.

Agriculture.—Formerly most of the people of Alabama were dependent upon agriculture for a living; but in the last 20 years, according to the department of Agriculture, farm population has

1. Birmingham, chief industrial city of the Southern States since the development of the coal mining interests of Alabama, U.S.A.

2. Aerial view of Montgomery, capital of the State of Alabama, U.S.A., showing the bend in the Alabama river

decreased from 64.7% in 1910 to 56.8% in 1920 and still further to 47.3% in 1925. By actual count the farm population decreased 169,453 from 1920 to 1925. The cause of this is to be found in the migration of farmers to cities, especially of negro farmers to northern cities. Correspondingly, the number of farms decreased from 262,901 in 1910 to 256,099 in 1920, and then to 237,562 in 1925. In 1879 the value of all crops was \$56,872,994, and in

GRAPH SHOWING THE PRODUCTION OF COTTON BETWEEN 1909 AND 1926

1919, \$304,348,638; then it fell off to \$174,779,000 in 1926. Approximately one-third of the farms are managed by their owners, one-third by cash renters, and one-third by share tenants. Cotton has regularly been the chief agricultural product, though in some years the value of the corn (maize) crop has been higher. The output of cotton increased from 7,000 bales in 1818 to nearly 1,000,000 bales in 1860, but did not again reach that figure until 1924. In the years when the boll weevil ruined the crop of the cotton belt, the other counties of the state, stimulated by the high prices, began to grow more cotton. The result was an output of 1,357,000 bales in 1925. Of the other agricultural products corn (maize), hay, peanuts, oats, wheat, potatoes, syrups, and cottonseed are the most important. The value of the fertilizer for cotton growing increased from \$9,521,000 in 1924 to \$14,587,000 in 1926.

Minerals.—The chief feature of the industrial life of Alabama since 1880 has been the exploitation of her iron and coal resources. Bituminous coal, first mined near Tuscaloosa about 1827, was produced intensively after 1881; the output grew from 946 tons in 1840 and 13,200 short tons in 1870 to 420,000 tons in 1881 and 1,568,000 tons in 1883. In 1923, according to the bureau of mines, the output reached 20,457,649 short tons, with a value of \$51,624,000, but declined in 1924 to 19,130,184 short tons with a value of \$44,756,000. Most of the coal comes from Jefferson, Walker and Bibb counties, though the coal-bearing formations cover about 40% of the northern half of the state. It is estimated that the total available coal resources of Alabama amount to 66,711,378,260 short tons, enough to last 3,335 years at the present rate of extraction. The iron ore, which is primarily red haematite, is found chiefly in the region of which Birmingham is the centre. In 1905, Alabama produced 3,782,831 tons of iron ore; in 1923 there were shipped from mines 6,922,663 long tons, valued at \$15,540,198; and in 1924, 6,557,596 long tons, valued at \$13,927,551 (as reported by the bureau of mines). In 1924, Alabama stood third among the states of the Union in the production of iron ore. Gold, silver, lead, copper, tin, graphite and bauxite are also produced. In 1924, Alabama produced minerals to the value of \$77,315,758, ranking 18th among the states, and producing 1.65% of the product of the whole Union. Coal, iron

ore, cement and clay products were the chief mineral products of the state.

Manufactures.—The growth of manufactures in Alabama has been as remarkable as the revelation of mineral wealth. In 1880, the capital invested in manufactures was \$9,668,008, little more than that in 1860; by 1890, it had increased to \$46,122,571; in 1900, it amounted to \$70,370,081; in 1909, to \$173,180,038; and in 1919 to \$455,592,733. On account of the proximity of coal, iron and limestone, the manufactures of iron and steel are the most extensive. The first blast furnace in Alabama was set up in 1818; from then until the Civil War numerous Catalan forges were in operation. In 1876, the first pig iron with coke for fuel was produced. In 1895, it was demonstrated that Alabama pig iron could be sent to Liverpool and sold cheaper than the English product, and Birmingham (Alabama) came consequently to rank next to Middlesbrough and Glasgow among the world centres of the pig iron trade. The pig iron produced in the state in 1860 was valued at \$64,590; in 1880, at \$1,405,536; in 1900, at \$13,487,769; and in 1923, at \$63,561,614. Manufacture of steel and steel products began in 1888, but was not successful until the Duplex process was used. On account of the irregular quantities of iron and phosphorus present in Alabama ores, this special process, representing a combination of the Bessemer and open-hearth processes, must be used. Recently Brazilian ores have been imported. Improvements in transportation facilities, such as railway, docks, and steamship lines, have enabled Alabama steel products to compete with those of the rest of the world in the South American market. By 1923, Alabama ranked seventh among the states in steel products, her output being worth \$75,042,823. To meet the demand for coke from the iron and steel industries, the coke output rose to the value of \$44,577,384 in 1923. The greater part of the pig-iron produced in Alabama and not used in the manufacture of steel is made into cast-iron pipe, mostly in the Birmingham district, the value of the 1923 output being \$40,142,807, nearly half the entire output of the United States. Since 1910, there has been a remarkable development of the cement industry, due to the presence of practically inexhaustible deposits of limestone in the heart of rich coal fields, side by side with extensive areas of shale and clay, in a territory served by

STEEL MILLS IN OPERATION AT BIRMINGHAM, ALABAMA

The coal formation, which underlies about 20% of the area of the State, is responsible for the development of the steel and iron mills that make Birmingham the chief industrial centre of the South

adequate hydro-electric power. In 1924, the output of cement was 5,542,687 barrels, valued at \$9,147,367.

Lumber and naval stores are produced in great quantities. In 1923, the product of sawed lumber was valued at \$52,792,121, of which yellow pine represented \$46,289,706, oak \$1,474,347, and poplar \$1,307,823. From 1890 to 1924 the number of turpentine factories increased from 7 to 131; and the output of turpentine and rosin products was valued at \$2,434,365 in 1905, and at \$2,809,815 in 1923.

The manufacture of cotton goods has also developed rapidly. As late as 1890, there were only 13 cotton mills in Alabama, one

more than the number in 1850; in 1900, there were 31, with an annual product valued at \$8,153,136, an increase of 272.2% over the product (\$2,190,771) of 1890; by 1923, there were 61 establishments, employing 20,785 people, with products valued at \$86,384,725, giving the state seventh place in the production of cotton goods.

In the 28 years from 1899 to 1927, the value of Alabama's manufactured products rose from \$72,109,929 to \$550,372,126. In 1927, Jefferson county, in which Bessemer and Birmingham are situated, produced 48% of the total for the whole state.

The use of hydro-electric power for the manufacturing establishments has recently been increased. Two great dams across the Coosa river and the U.S. Government dam at Muscle Shoals

Mobile, the only seaport in Alabama, is the terminus of the road and waterway system that transports products for shipment from the inland plantations, mines and steel mills

(*q.v.*) on the Tennessee river are already completed; others are under construction.

Transportation.—Alabama rivers are navigable for a total distance of 2,000 miles, but obstructions often prevent the formation of a continuous route. The U.S. Government has spent millions of dollars on the elimination of these impediments, as well as on the improvement of Mobile harbour. National, state and city funds have been used to improve the facilities of the port of Mobile. During the closing months of 1920, the first vessel of a fleet of government-owned and operated self-propelling barges made its way down the Mississippi river to New Orleans and into the gulf, then to Mobile and up the rivers to Birmingham and Cordova in the heart of the Warrior coal fields. A balanced tonnage, up and down stream, is steadily being developed by the trans-shipment at Mobile of manganese ore from Brazil, for use in making high-grade steel in the Birmingham district, and by the establishment of an all-water freight rate from New York and other eastern points, via Mobile, to the various river ports.

An amendment to the state constitution having authorized the use of the credit of the state for the construction of a great system of docks at Mobile, an act of the legislature at its session of 1923-24 authorized the issue of \$10,000,000 of bonds for that purpose and a commission was put in charge of the work. The commission thereupon acquired for the state approximately 400 acres of land, with a water frontage of two miles on the northern outskirts of the city.

As the streams in the mineral region are not navigable, the railways are the carriers of its products. Here all the large systems of the southern states find an entrance—the Mobile and Ohio, the Southern (Queen and Crescent route), the Louisville and Nashville, and the San Francisco system affording communication with the Mississippi and the west, and the Southern, the Seaboard air line, the Atlantic coast line, and the Central of Georgia forming connections with northern and Atlantic states. The total mileage of railway in the state is 5,281.

HISTORY

The first Europeans to enter the limits of the present state of Alabama were Spaniards, who claimed this region as a part of

Florida. The first fully authenticated visit was that of Hernando de Soto, who journeyed along the Coosa, Alabama, and Tombigbee rivers in 1539-40. The English, too, claimed the region north of the Gulf of Mexico, and the territory of modern Alabama was included in the province of Carolina by the charters of 1663 and 1665. English traders from Carolina were frequenting the valley of the Alabama river as early as 1687. Fort Condé, the germ of the present city of Mobile, and the first permanent white settlement in Alabama, was founded by the French in 1711. Later, on account of intrigues between English traders and the Indians, the French as a means of defence established several military posts. The grant of Georgia to Gen. J. E. Oglethorpe and his associates in 1732 included a portion of what is now northern Alabama, and in 1739 Oglethorpe himself visited the Creek Indians west of the Chattahoochee river and made a treaty with them. The treaty of Paris, in 1763, terminated the French occupation, and England came into undisputed possession of the region between the Chattahoochee and the Mississippi. The portion of Alabama below the 31st parallel then became a part of West Florida, and the portion north of this line a part of the "Illinois country," set apart, by royal proclamation, for the use of the Indians. In 1767 the province of West Florida was extended northward to 32° 28' N., and a few years later, during the War of Independence, this region fell into the hands of Spain. By the treaty of Versailles, on Sept. 3, 1783, England ceded West Florida to Spain; but by the treaty of Paris, signed the same day, she ceded to the United States all of this province north of 31°, and thus laid the foundation for a long controversy. By the treaty of Madrid, in 1795, Spain ceded to the United States her claims to the lands east of the Mississippi between 31° and 32° 28'; and three years later (1798) this district was organized by Congress as the Mississippi territory. A strip of land 12 or 14 m. wide near the present northern boundary of Alabama and Mississippi was claimed by South Carolina; but in 1787 she ceded this claim to the general Government. Georgia claimed all the lands between the 31st and 35th parallels from its present western boundary to the Mississippi river, a claim not surrendered until 1802; two years later the boundaries of the Mississippi territory were extended so as to include all of the Georgia cession. In 1812 Congress annexed to the Mississippi territory the Mobile district of West Florida, claiming that it was included in the Louisiana purchase; and in the following year Gen. J. Wilkinson occupied this district with a military force, the Spanish commandant offering no resistance. The whole area of the present state of Alabama then for the first time became subject to the jurisdiction of the United States. In 1817 the Mississippi territory was divided; the western portion became the state of Mississippi, and the eastern the territory of Alabama, with St. Stephens, on the Tombigbee river, as the temporary seat of government. In 1819 Alabama was admitted to the Union as a state.

Early Difficulties: Finance.—One of the first problems of the new commonwealth was that of finance. Since the amount of money in circulation was insufficient to meet the demands of the increasing population, a system of state banks was instituted. State bonds were issued and public lands sold to secure capital. The notes of the banks, loaned on security, became a medium of exchange. Prospects of an income from the banks led the legislature of 1836 to abolish all taxation for state purposes. This was hardly done, however, before the panic of 1837 wiped out a large portion of the banks' assets; next came revelations of careless and corrupt management, and in 1843 the banks were placed in liquidation. After disposing of all their available assets, the state assumed the remaining liabilities, for which it had pledged itself.

The Indian Problem.—The Indian problem was important. With the encroachment of the white settlers upon their hunting-grounds the Creek Indians grew restless, and the great Shawnee chief Tecumseh, who visited them in 1811, fomented their discontent. When the outbreak of the second war with Great Britain in 1812 gave the Creeks assurance of British aid they rose in arms, massacred several hundred settlers who had taken refuge in Fort Mims, near the junction of the Alabama and Tombigbee rivers, and soon no white family in the Creek country was safe outside

a palisade. The Chickasaw and Choctaw Indians, however, remained the faithful allies of the whites, and volunteers from Georgia, South Carolina and Tennessee, and later United States troops under Gen. Andrew Jackson, broke forever the power of the Creek confederacy. By the treaty of Fort Jackson (Aug. 9, 1814) the Creeks ceded their claims to about one-half of the present state; and cessions by the Cherokees, Chickasaws and Choctaws in 1816 left the Indians only about one-fourth of Alabama. In 1832 the national Government provided for the removal of the Creeks; but before the contract was effected, the state legislature formed the Indian lands into counties, and settlers flocked in. A disagreement ensued between Alabama and the United States authorities; although it was amicably settled, it engendered a feeling that the policy of the national Government might not be in harmony with the interests of the state—a feeling which, intensified by the slavery agitation, did much to cause secession in 1861.

Political History.—The political history of Alabama may be divided into three periods—that prior to 1860, from 1860 to 1876, and from 1876 onwards.

The first is the only period of altogether healthy political life. Until 1832 the democratic was the only party in the state, but the question of nullification caused a division that year into the (Jackson) democratic party and the States' rights (Calhoun democratic) party; about the same time, the whig party was formed chiefly in counties where slaves were most numerous and the free-men most aristocratic. For some time the whigs were nearly as numerous as the democrats, but they never controlled the state Government. The States' Rights men were in a minority; nevertheless, under their active and persistent leader, W. L. Yancey (1814–1863), they prevailed upon the democrats in 1848 to adopt their most radical views.

The Alabama Platform.—During the agitation over the introduction of slavery into the territory acquired from Mexico, Yancey induced the democratic state convention of 1848 to adopt what is known as the "Alabama platform," which declared that neither Congress nor the government of a territory had the right to interfere with slavery in a territory, that those who held opposite views were not democrats, and that the democrats of Alabama would not support a candidate for the presidency if he did not agree with them on these questions. This platform was endorsed by conventions in Florida and Virginia and by the legislatures of Georgia and Alabama. Old party lines were broken by the compromise of 1850. The States' rights party, joined by many democrats, founded the southern rights party, which demanded the repeal of the compromise, advocated resistance to future encroachments, and prepared for secession, while the whigs, joined by the remaining democrats, formed the party known as the "unionists," which unwillingly accepted the compromise and denied the constitutional right of secession. The unionists were successful in the elections of 1851 and 1852, but the feeling of uncertainty engendered in the south by the passage of the Kansas-Nebraska bill and the course of the slavery agitation after 1852 led the state democratic convention of 1856 to revive the Alabama platform; and when the Alabama platform failed to secure the formal approval of the democratic national convention at Charleston, South Carolina, in 1860, the Alabama delegates, followed by those of the other cotton states, withdrew. Upon the election of Abraham Lincoln, Governor Andrew B. Moore, in obedience to previous instructions of the legislature, called a state convention on Jan. 7, 1861. After long debate it adopted on Jan. 11 an ordinance of secession, and Alabama became one of the Confederate states of America, whose government was organized at Montgomery Feb. 4, 1861. Yet many prominent men opposed secession, and in northern Alabama, where there were very few slaves, an attempt was made to organize a neutral state, Nickajack; but with President Lincoln's call to arms all opposition to secession ended.

The Civil War.—In the early part of the Civil War, Alabama was not the scene of military operations, yet the state contributed about 120,000 men to the Confederate service, practically all her white population capable of bearing arms; 39 of these

attained the rank of general. In 1863 the Federal forces secured a foothold in northern Alabama in spite of the opposition of Gen. N. B. Forrest, one of the ablest Confederate cavalry leaders. In 1864 the defences of Mobile were taken by a Federal fleet, but the city held out until April 1865; in the same month Selma fell.

Reorganization After the Civil War.—According to the presidential plan of reorganization, a provisional governor for Alabama was appointed in June 1865; a state convention met in September and declared the ordinance of secession null and void and slavery abolished; a legislature and a governor were elected in November; the legislature was at once recognized by the national Government, and the inauguration of the governor-elect was permitted after the legislature had, in December, ratified the 13th amendment. But the passage, by the legislature, of vagrancy and apprenticeship laws designed to control the negroes flocking from the plantations to the cities, and its rejection of the 14th amendment, so intensified the congressional hostility to the presidential plan that the Alabama senators and representatives were denied their seats in Congress. In 1867 the congressional plan of reconstruction was completed and Alabama placed under military government. Negroes were now enrolled as voters and large numbers of white citizens disfranchised. A black man's party, composed of negroes and political adventurers known as "carpet-baggers," was formed, which co-operated with the republican party. A constitutional convention, controlled by this element, met in Nov. 1867 and framed a constitution which conferred suffrage on negroes and disfranchised a large class of whites. As the whites stayed away from the polls, thus preventing the required majority of legal voters, Congress enacted that a majority of the votes cast should be sufficient, and thus the constitution went into effect, the state was admitted to the Union in June 1868, and a new governor and legislature elected.

The next two years are notable for legislature extravagance and corruption. The state endorsed railway bonds at the rate of \$12,000 and \$16,000 a mile until the state debt had increased from \$8,000,000 to \$17,000,000, and similar corruption characterized local government. The native white people united, formed a conservative party, and elected a governor and a majority of the lower house of the legislature in 1870; but, as the new administration was largely a failure, in 1872 there was a reaction in favour of the radicals, as the republicans were locally known. Affairs went from bad to worse. In 1874, however, the power of the radicals was finally broken, the conservative democrats electing all state officials. A commission appointed to examine the

state debt found it to be \$25,503,000; by compromise it was reduced to \$15,000,000. A new constitution was adopted in 1875, which omitted the guaranty of the previous constitution that no one should be denied suffrage on account of race, colour or previous condition of servitude, and forbade the state to engage in internal improvements or to give its credit to private enterprise.

The Effects of Industrial Development.

Since 1874, the democratic party has controlled the state administration, the republicans failing to make nominations for office in 1878 and 1880, and endorsing the ticket of the greenback party in 1882. The development of mining and manufacturing was accompanied by economic distress among the farming classes, which found expression in the Jeffersonian democratic party, organized in 1892. The regular democratic ticket was elected and the new party merged with the populist party. In 1894 the republicans united with the populists, elected three congressional representatives, and secured control of many of the counties, but failed to carry the state and continued their opposition with less success

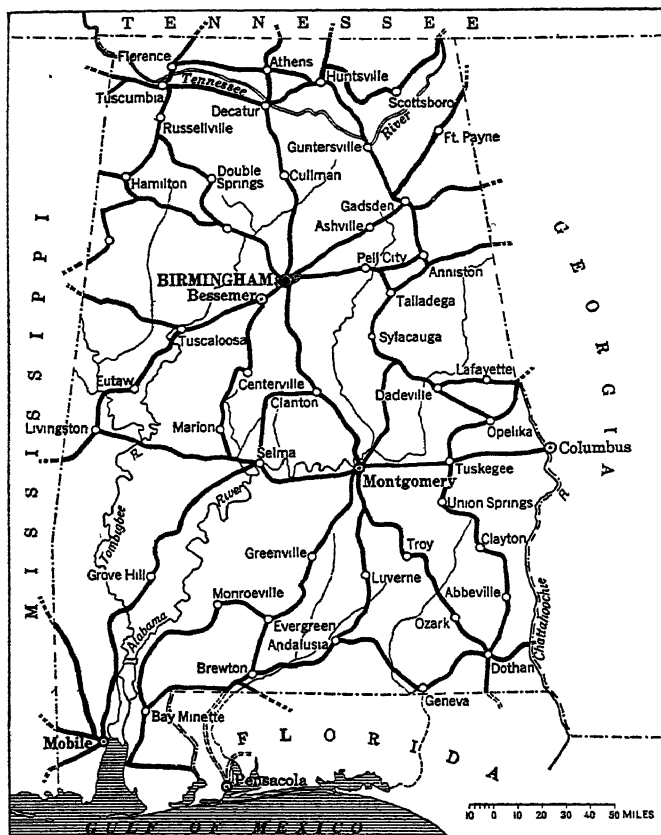

CHART SHOWING THE INCREASE IN ELECTRIC POWER GENERATED IN ALABAMA FROM 1907-1922

in the next campaigns. Partisanship became intense and charges of corruption of the negro electorate were made. Consequently, after division on the subject among the democrats themselves, as well as opposition from republicans and populists, a new constitution with restrictions on suffrage was adopted in 1901. The new restrictions resulted in the virtual elimination of the negro vote and therefore in a reduction of the republican vote. The

THE MAIN ROUTES AND PRINCIPAL MOTOR HIGHWAYS OF ALABAMA

republican party, which had polled 54,737 votes in the presidential election of 1896 and 55,634 votes in the election of 1900, polled only 22,472 votes in the election of 1904. Its vote remained at about that level until 1920, when the effects of economic changes began to appear in elections. In the presidential election of that year the republican vote was 74,690, or 31.9% of the vote cast—more than enough to secure the privilege of a primary for the nomination of candidates in the next election, at the expense of the state Government. The gains of the republican party were registered chiefly in the growing industrial districts, such as Chilton, DeKalb, St. Clair and Winston counties, in which the party polled majorities, and in Blount, Clay, Cullman, Jefferson, Marshall, Shelby and Walker counties, in which it polled strong minorities. Although its vote fell off to 45,005 in 1924, the striking increase in the republican vote from 1904 to 1924 and the appearance of a socialist vote are considered by many the normal result of industrial development and by some as a sign of the future break-up of the "solid south."

Two important amendments were added to the constitution of 1901: one provided for local option by counties and school districts as to increased taxation for public schools; the other authorized the issue of state bonds to the amount of \$25,000,000 for the construction of a complete system of highways, thus securing for the state the national appropriations in aid of that policy, and in 1927 an additional \$25,000,000 was authorized, for the continuance of the work. At its regular session in 1919 the legislature refused to ratify the 19th amendment to the constitution of the United States, providing for woman suffrage; but when the requisite number of states had made it a part of the constitution, a special session was called (1920) which promptly passed an

act providing for the registration of women voters and for otherwise carrying into effect the provisions of the amendment. In 1921 a proposed amendment to the state constitution to provide additional qualifications for registering and voting was rejected by the people.

BIBLIOGRAPHY.—For an elaborate bibliography of Alabama, see T. M. Owen, *Annual Report of the American Historical Association* for 1897 (1898). Information regarding the resources, climate, population and industries of Alabama may be found in the reports of the United States Census; the publications of the United States Department of Agriculture and the United States Geological Survey; the bulletins of the Alabama Agricultural Experiment Station (published at Auburn, from 1888); the bulletins and reports of the Alabama Geological Survey (published at Tuscaloosa and Montgomery); and the following works: *Alabama Handbook: Agricultural and Industrial Resources and Opportunities* (Montgomery, 1919); R. M. Harper, *Resources of Southern Alabama* (1920). The history of the state may be found in J. A. Pickett, *A History of Alabama* (Charleston, 1851); W. R. Smith, *Debates in the Secession Convention of Alabama* (Montgomery, 1861); W. Brower, *Alabama* (Montgomery, 1872); W. Garrett, *Reminiscences of Public Men in Alabama* (Atlanta, 1872); P. J. Hamilton, *Colonial Mobile* (1897); *Publications of the Alabama Historical Society* (Montgomery); J. C. DeBose, *Alabama History* (Richmond, 1908); T. M. Owen, *History of Alabama and Dictionary of Alabama Biography* (1921), the first two volumes devoted to an exhaustive topical treatment of the history of the state and the last two to biography. See also W. L. Fleming, *Civil War and Reconstruction in Alabama* (1905); T. P. Abernethy, *The Formative Period in Alabama, 1815-1828* (Montgomery, 1922). *The biennial Alabama Official and Statistical Register* (Montgomery), published by the state department of archives and history, gives the names of all officials, the election statistics, etc. For government see H. L. McBain and J. W. Hill, *How We are Governed in Alabama and the Nation* (1914).

"ALABAMA" ARBITRATION. The facts of this case are as follows: In 1861 the Southern States of North America seceded and set up a separate government. Hostilities began with the capture of Fort Sumter by the Confederates on April 13, 1861. On the 19th President Lincoln declared a blockade of the southern ports. On May 14 the British government issued a proclamation of neutrality, by which the Confederates were recognized as belligerents. This example was followed shortly afterwards by France and other States. In June 1862 the vessel, the "Alabama," originally known as "No. 290," was being built by Messrs. Laird at Birkenhead. She was then nearly completed and was obviously intended for a man-of-war. On June 23 Mr. C. F. Adams forwarded to Earl Russell a letter from the United States consul at Liverpool giving certain particulars as to her character. This letter was laid before the law officers, who advised that, if these particulars were correct, the vessel ought to be detained. On July 21 sworn evidence, which was supplemented on July 23, was obtained and laid before the commissioners of customs (who were the proper authorities to enforce the provisions of the Foreign Enlistment Act of 1819), but they declined to move. On July 23, the same evidence was laid before the law officers, who advised that there was sufficient ground for detention. By some accident, the papers were not returned till July 29. Instructions were then issued to seize the vessel, but she had already sailed on the evening of the 28th. Although she remained for two days off the coast of Anglesey, there was no serious attempt at pursuit. She afterwards made her way to the Azores, where she received her armament, which was brought from Liverpool in two British ships. Captain Semmes there took command of her under a commission from the Confederate Government. After a most destructive career she was sunk off Cherbourg by the "Kearsarge" on June 19, 1864.

On these facts the United States Government alleged against Great Britain two grievances: first the recognition of the Southern States as belligerents and a general manifestation of unfriendliness in other ways; second, the breach of neutrality in allowing the "Alabama," the "Florida," the "Shenandoah" and other Confederate vessels to be built and equipped on British territory. Correspondence ensued extending over several years and in 1871 a commission was appointed to determine the mode in which the questions at issue might be settled. The British commissioners suggested that the "Alabama" should be submitted to arbitration. The American commissioners refused "unless the principles which should govern the arbitrators in the considera-

tion of the facts could be first agreed." Eventually it was agreed that the three following rules should apply: A neutral government is bound—(1) to use due diligence to prevent the fitting out, arming or equipping within its jurisdiction of any vessel, which it has reasonable ground to believe is intended to cruise or to carry on war against a power with which it is at peace, and also to use like diligence to prevent the departure from its jurisdiction of any vessel intended to cruise or carry on war as above, such vessel having been specially adapted, in whole or in part, within such jurisdiction, to warlike use; (2) not to permit or suffer either belligerent to make use of its ports or waters as the base of naval operations against the other, or for the purpose of the renewal, or augmentation of military supplies or arms or the recruitment of men; (3) to exercise due diligence in its own ports and waters and as to all persons within its jurisdiction to prevent any violation of the foregoing obligation and duties. These rules were embodied in the treaty of Washington (1871), which provided that the "Alabama" claims should be referred to a tribunal composed of five arbitrators, one to be named by each of the contracting parties and the remainder by three neutral powers. Art. 6 provided that the arbitrators should be governed by the three rules quoted above, and by such principles of international law not inconsistent therewith as the arbitrators should determine to be applicable to the case. By the same article the parties agreed to observe these rules as between themselves in future, and to bring them to the knowledge of other maritime powers. Art. 7 gave power to the arbitrators to award a sum in gross if Great Britain were adjudged in the wrong.

The treaty was, on the whole, welcomed in England. The United States appointed Mr. C. F. Adams as arbitrator and Mr. J. C. Bancroft Davis as agent. The British government appointed Sir Alexander Cockburn as arbitrator and Lord Tenterden as agent. The arbitrators appointed by the three neutral powers were Count Sclopis (Italy), M. Staempfli (Switzerland), Baron d'Itajuba (Brazil). The first meeting of the tribunal took place on Dec. 15, 1871, in Geneva. As soon as the cases had been formally presented, the tribunal adjourned till the following June. There followed immediately a controversy which threatened the collapse of the arbitration. The United States claimed damages not only for the property destroyed by the Confederate cruisers, but for such "indirect losses" as the transference of the American marine to the British flag, the enhanced payments of insurance, the expenses of pursuit and the prolongation of the war. They also revived the charges of "insincere neutrality" and "veiled hostility" which had figured in the diplomatic correspondence, and had been repudiated by Great Britain, and dwelt at length upon the premature recognition of belligerency, the unfriendly utterances of British politicians and the material assistance afforded to the Confederates by British traders. These claims for indirect losses, etc., caused great excitement in England. That they were within the treaty was disputed, and it was argued that, if they were, the treaty should be amended or denounced. In Oct. 1872 Lord Granville notified to General Schenck, the United States minister, that the British government did not consider that the indirect losses were within the submission, and in April the British counter-case was filed without prejudice to this contention. On June 15 the tribunal reassembled and the American argument was filed. To save the situation Mr. Adams persuaded his colleagues to make a spontaneous declaration that by the principles of international law the indirect claims ought to be excluded from their consideration. The discussion then turned mainly on the question of the measure of "due diligence." The United States contended that it must be a diligence commensurate with the emergency or with the magnitude of the results of negligence. The British government maintained that while the measure of care which a government is bound to use in such cases must be dependent more or less upon circumstances, it would be unreasonable to require that it should exceed that which the governments of civilized States were accustomed to employ in matters concerning their own security or that of their citizens.

The tribunal adopted the view suggested by the United States.

It found that Great Britain was legally responsible for all the depredations of the "Alabama" and "Florida" and for those committed by the "Shenandoah" after she left Melbourne. In the case of the "Alabama" the court was unanimous; in the case of the "Florida" Sir A. Cockburn alone, in that of the "Shenandoah" he and Baron d'Itajuba, dissented from the majority. In the cases of the other vessels the judgment was in favour of Great Britain. The tribunal decided to award a sum in gross, and (Sir A. Cockburn again dissenting) fixed the damages at \$15,500,000 in gold. On Sept. 14 the award was formally published, and signed by all the arbitrators except Sir A. Cockburn, who filed a lengthy statement of his reasons.

The first of the Washington Rules, with the substitution of the words "the means at its disposal" for the words "due diligence," was adopted by Art. 8 of the Hague Convention XIII., 1907.

See L. A. Atherley-Jones and H. H. L. Bellot, *Commerce in War* (1907). (H. H. L. B.)

ALABAMA CITY, a city of Etowah county, Alabama, U.S.A., 60m. N.E. of Birmingham; 2½m. N.W. of Gadsden. It is served by the Southern, the Louisville and Nashville, and the Nashville, Chattanooga and St. Louis railways. The population was 5,432 in 1920, and was 8,544 in 1930 by the Federal census. It has large cotton mills and steel factories. Coal and iron are mined in the vicinity.

ALABAMA RIVER, a river of Alabama, U.S.A., formed by the Tallapoosa and Coosa rivers, which unite about 6m. above Montgomery. It flows west as far as Selma, then south-west until, about 45m. from Mobile, it unites with the Tombigbee to form the Mobile and Tensas rivers, which discharge into Mobile bay. The course of the Alabama is tortuous; its width varies from 600 to 900ft., its depth from 3 to 7ft.; its length by the United States Survey is 312m.; by steamboat measurement, 420m. The river crosses the richest agricultural and timber districts of the State, and railways connect it with the mineral regions of north central Alabama. The principal tributary of the Alabama is the Cahaba (about 200m. long), which enters it about 10m. below Selma. Of the rivers which form the Alabama, the Coosa crosses the mineral region of Alabama, and is navigable for light-draft boats from Rome, Georgia (where it is formed by the junction of the Oostenaula and Etowah rivers), to about 117m. above Wetumpka (about 192m. below Rome and 26m. below Greensport), and from Wetumpka to its junction with the Tallapoosa; the channel of the river has been considerably improved by the Federal government. The navigation of the Tallapoosa river (which has its source in Paulding county, Ga., and is 250m. long) is prevented by shoals and a 60ft. fall at Tallassee, a few miles north of its junction with the Coosa. The Alabama, which is navigable throughout the year, is an important carrier of cotton, cotton seed, fertilizer, cereals, lumber and naval stores.

ALABASTER or ARBLASTIER, WILLIAM (1567–1640), English Latin poet and scholar, was born at Hadleigh, Suffolk, and was educated at Westminster school and Trinity college, Cambridge. Alabaster served with the expedition of Robert Devereux, earl of Essex, to Cadiz in 1596, and embraced the Roman Catholic faith while he was in Spain. He was imprisoned in the Tower for his religious opinions in 1598 and 1599. His mystical writings brought him into conflict with the Inquisition, and he was imprisoned in Rome for a short time. He escaped, returned to England, abjured Catholicism and received a prebend in St. Paul's Cathedral, which he held until his death in April 1640.

Alabaster's Latin tragedy, *Roxana*, written while he was at Cambridge, is modelled on *La Dalida* of Luigi Groto, and was first published in 1632. Samuel Johnson praised it as the only Latin verse worthy of note written in England before Milton's *Elegies*. One book of an epic poem in praise of Elizabeth, entitled *Elisaeis, apotheosis poetica*, is preserved at Emmanuel college, Cambridge. It was admired by Edmund Spenser. "Who lives that can match that heroic song?" he says in "*Colin Clout's come home againe*." Other works by Alabaster are mystical in character and owe much to his study of the Kabbala. They include *Apparatus in revelationem Jesu Christi* (Antwerp, 1607), *Ecce*

Sponsus venit (1633), *Lexicon Pentaglotton* (1637) and mystical commentaries on Revelations and the Pentateuch.

See T. Fuller, *Worthies of England* (ii. 343); Pierre Bayle, *Dictionnaire, Historical and Critical* (1734); J. P. Collier, *Bibl. and Crit. Account of the Rarest Books in the English Language* (vol. i. 1865); also the *Athenaeum* (Dec. 26, 1903), where Mr. Bertram Dobell describes a ms. in his possession containing 43 sonnets by Alabaster.

ALABASTER, a name applied to two different mineral substances. The alabaster of the ancients is mostly a granular aggregate of crystals of calcium carbonate—*i.e.*, it is really a marble (*q.v.*). The alabaster of modern times is a granular form of the mineral gypsum (*q.v.*). It is usually white, pink or yellowish in colour, often with darker streaks and patches, and is very soft (hardness 1.5 to 2) so that it can be scratched by the finger nail. It can be readily distinguished from marble by the fact that it does not effervesce with acid. Alabaster is found in beds interstratified with red sandstones and marls deposited in the beds of salt lakes during an arid period: in England, chiefly in the Keuper marls of the midlands, especially at Chellaston in Derbyshire, Fauld in Staffordshire, and near Newark, Nottinghamshire, also in the neighbourhood of Carlisle, near Watchet in Somerset and Penarth in Glamorgan, all in the Trias.

On the Continent the centre of the alabaster trade is Florence, where it is found in Miocene and Pliocene strata, and is extensively used for statuary work and carving of ornamental objects. The best kind is pure white and translucent, but by careful heating in nearly boiling water it can be made nearly opaque, resembling marble. This appears to be due to partial dehydration.

(R. H. RA.)

ALABASTROS or **ALABASTOS**, a Greek vase, shaped like an urn. The most common type of the alabastros stands on a base that balances, in appearance, its rather wide mouth. (See POTTERIES AND PORCELAINS: *Greek Pottery*.)

ALACALUF, an Indian tribe, almost extinct, living in the west Patagonian channels, chiefly in the vicinity of Ración sound. Formerly they were much more numerous, and their canoes might be seen southward from the Gulf of Peñas to Brecknock peninsula in Tierra del Fuego, including the Straits of Magellan. Their culture in general closely resembles that of the other canoe-using tribe of Tierra del Fuego, the Yahgan (*q.v.*). The use of planked canoes by the Alacaluf has suggested the possibility of culture transference from Polynesia, but the Alacaluf planked canoe is demonstrably a local development.

See J. M. Cooper, "Analytical and Critical Bibliography . . . of Tierra del Fuego," in *Bureau of American Ethnology Bulletin* 63 (1917).

ALACOQUE or **AL COQ**, **MARGUERITE MARIE** (1647–1690), French nun and founder of the devotion to the Sacred Heart of Jesus, was born at Lauthcourt on July 22, 1647, and died on Oct. 17, 1690. Having been cured of paralysis, as she believed by the intercession of the Blessed Virgin, in 1671 she entered the Visitation convent at Paray-le-Monial and in the following year made her final vows. After a long period of severe austerities she testified that Christ had revealed to her His heart burning with love for man, and bade her establish the Holy Hour, communion on the first Friday of the month and the feast of the Sacred Heart to be observed on the Friday after the octave of Corpus Christi. The devotion to the Sacred Heart spread rapidly throughout Christendom, and Marguerite Marie was pronounced venerable in 1824, blessed in 1864, and finally on May 13, 1920, was canonized.

Her writings and autobiography are contained in *Vie et Oeuvres par les Contemporaines*, 2 vols. (Paris, 1901), her autobiography being published again at Paray-le-Monial in 1918. See also E. Bougaud, *Life of St. Margaret Mary Alacoque* (New York, 1920).

ALAGOAS, a maritime state of Brazil, bounded north and west by the State of Pernambuco, south and west by the State of Sergipe, and east by the Atlantic. It has an area of 22,584 square miles. A dry, semi-barren plateau, fit for grazing only, extends across the western part of the State, breaking down into long fertile valleys and wooded ridges towards the coast, giving the country a mountainous character. The coastal plain is filled with lakes (*lagoas*), in some cases formed by the blocking up of river outlets

by beach sands. The valleys and slopes are highly fertile and produce sugar, cotton, tobacco, Indian corn, rice, mandioca and fruits. Hides and skins, mangabeira rubber, cabinet woods, castor beans and rum are also exported. Cattle-raising was formerly a prominent industry, but it has greatly declined. Manufactures have been developed to a limited extent only, though protective tariff laws have been adopted for their encouragement. The climate is hot and humid, and fevers are prevalent in the hot season. The capital, Maceio, is the chief commercial city of the State, and its port (Jaragua) has a large foreign and coastwise trade. The principal towns are Alagoas, formerly the capital, picturesquely situated on Lake Manguaba, 15m. south-west of Maceio, and Penedo, a small port on the lower São Francisco, 26m. above the river's mouth. Before 1817 Alagoas formed part of the capitania of Pernambuco, but in that year the district was rewarded with a separate government for refusing to join a revolution, and in 1823 became a province of the empire. The advent of the republic in 1889 changed the province into a State.

ALAIN DE LILLE (Alanus de Insulis) (c. 1128–1202), French theologian and Latinist, lived at Montpellier, and finally retired to the Abbey of Cîteaux, where he remained until his death. His varied learning won for him the title of *Doctor universalis*. He was famed in his day for two of his Latin poems, *De planctu naturae*, a satire on human vices, and *Anticlaudianus*, a long verse treatise on the arts and on morals. Alain shared in the reaction against scholasticism, and laid stress on the share of faith in the apprehension of religious truth. He must be classed with the so-called Summists. But his *De arte seu de articulis catholicae fidei*, which was a "summa" of Christian theology, brings the principles of mathematical science to bear on Christian dogma. He also wrote a treatise *contra haereticos*.

The works of Alain de Lille have been published by Migne, *Patrologia latina*, vol. ccx. A critical edition of the *Anticlaudianus* and of the *De planctu naturae* is given by Th. Wright in vol. ii. of the *Anglo-Latin Satirical Poets and Epigrammatists of the Twelfth Century* (London, 1872). See Hauréau, *Mémoire sur la vie et quelques oeuvres d'Alain de Lille* (Paris, 1885); M. Baumgartner, *Die Philosophie des Alanus de Insulis* (Münster, 1896).

ALAIS: see **ALES**.

ALAJUELA, one of the four plateau cities containing most of the inhabitants of Costa Rica, Central America; the population in 1925 was 31,692. Alajuela is situated 14m. W. of San José on a branch line of the Costa Rica railway and is also accessible by highway. It lies on the slope of Poas volcano and is one of the chief centres of the coffee industry of Costa Rica. It is also the centre of the sugar trade of Costa Rica, this product coming from the adjoining country in the lower altitudes. A number of villages, ranging in population from 1,000 to 4,000, are tributary to Alajuela.

ALAMANNI or **ALLEMANNI**, a German people first mentioned by Dio Cassius. They dwelt in the basin of the Maine, to the south of the Chatti (*q.v.*). They were a conglomeration of various tribes. The Hermunduri formed the preponderating element, and there were among the others the Iuthungi, Bucinobantes and Lentienses. From the 4th century A.D. onwards we hear also of the Suebi (*q.v.*) or Suabi. The Hermunduri belonged to the Suebi, but reinforcements from new Suebic tribes now moved westward. In later times the names Alamanni and Suebi seem to be synonymous. They were continually engaged in conflicts with the Romans, the most famous encounter being that at Strassburg, in which they were defeated by Julian (A.D. 357). Early in the 5th century the Alamanni crossed the Rhine and conquered and settled Alsace and a large part of Switzerland. In A.D. 495 they were conquered by Clovis, from which time they formed part of the Frankish dominions. The Alamanic and Swabian dialects survive in Swiss dialects, and in parts of South Germany, particularly Baden and Württemberg and also parts of Alsace.

See Dio Cassius lxxvii. et seq.; Ammianus Marcellinus, *passim*; Gregory of Tours, *Historia Francorum*, book ii.; O. Bremer in H. Paul, *Grundriss der germanischen Philologie* (2nd ed., Strasbourg, 1900), vol. iii. pp. 930 et seq.

ALAMANNI or **ALEMANNI, LUIGI** (1495-1556), Italian statesman and poet, was born at Florence. Luigi joined with others in an unsuccessful conspiracy against Giulio de' Medici, afterwards Pope Clement VII. He was obliged to take refuge in Venice, and, on the accession of Clement, to flee to France. When Florence shook off the papal yoke in 1527, Alamanni returned, and took a prominent part in the management of the affairs of the republic. On the restoration of the Medici in 1530 he had again to take refuge in France, where he enjoyed the favour both of Francis I. and Henry II. He died at Amboise on April 18, 1556. His best work, *La Coltivazione* (Paris, 1546), is a didactic poem, written in imitation of Virgil's *Georgics*. His *Opere Toscane* (Lyons, 1532) consists of satirical pieces written in blank verse. An unfinished poem, *Avarchide*, in imitation of the *Iliad*, was the work of his old age and has little merit. It has been said by some that Alamanni was the first to use blank verse in Italian poetry, but the distinction belongs rather to his contemporary Giangiorgio Trissino. He also wrote a poetical romance, *Girone il Cortese* (Paris, 1548); a tragedy, *Antigone*; a comedy, *Flora*, and other poems. His works were published, with a biography, by P. Raffaelli, as *Versi e prose di Luigi Alamanni* (Florence, 1859).

BIBLIOGRAPHY.—See G. Naro, *Luigi Alamanni e la coltivazione* (Syracuse, 1897), and C. Corso, *Un decennio di patriottismo di Luigi Alamanni* (Palermo, 1898).

ALAMBAGH, the name of a large park or walled enclosure, containing the ruins of a country house of the old Oudh court, as well as a beautiful garden, situated about 4m. from Lucknow, near the Cawnpore road, in the United Provinces of India. It was converted into a fort by the mutineers in 1857, and after its capture by the British was of importance in connection with the military operations around Lucknow. Sir Henry Havelock was buried in the garden.

ALAMEDA, a residential city of Alameda county, California, U.S.A., on an artificial island on the continental side of San Francisco bay, opposite to and about 6m. from San Francisco, and directly south of Oakland, from which it is separated by an estuary spanned by three bridges. South of the city, but within its boundaries, is Bay Farm island, which is practically the city's vegetable garden. Alameda is served by the Southern Pacific railway, and by electric trains or ferries to all the cities around the bay, and there is a traffic tube to Oakland under the canal. An industrial belt line, constructed and owned by the city, is operated jointly by the transcontinental railways which serve the East Bay district (see ALBERT LEA). Population was 28,806 in 1920; and was 35,033 in 1930 by the Federal census. Alameda has 14 miles of waterfront, including long stretches of sandy beach used for recreation, besides the large tracts suitable for commercial and industrial purposes. It has 60 miles of paved streets, all lighted by electricity. It has a municipal light and power plant; a \$1,250,000 high school; a municipal golf course; a community hotel; a city-planning commission; and an annual dahlia festival. The industries include large borax works and shipyards; a pottery and a lumber mill; and plants which make pencils, boxes, candy, engines and deep-well pumps. The fleet of a large salmon-packing association has its winter headquarters here. There are already large docks and warehouses, and the city has undertaken extensive developments on its western waterfront (estimated cost \$10,000,000). There was a settlement here before the end of the Mexican period. The town was incorporated in 1854 and in 1885 it was chartered as a city. In 1870 it had a population of 1,557; in 1880, of 5,708. It operates under a freehold charter, and has had the city-manager form of government since 1917.

ALAMO, THE, an historic building in San Antonio, Texas, noted as the scene of an heroic defence in the war between Texas and Mexico. This building is the chapel of the Mission San Antonio de Valero, founded in 1718 by Franciscans, and commonly called the "Alamo Mission" from the grove of cottonwood (*alamo*) in which it stood. It originally consisted of the chapel, a convent yard about 100ft. square, a convent and hospital building, and a plaza about 2½ac. in extent, the whole being sur-

rounded by a strong wall. Upon the disappearance of the Indians from the vicinity the mission was abandoned, and after 1793 it was sometimes used as a fort. In the war for Texan independence Cols. William B. Travis, James Bowie and Davy Crockett, with 180 men, were attacked here by 4,000 Mexicans commanded by Santa Anna. After a siege lasting 13 days, Feb. 23-March 6, 1836, during which some 500 of the attacking force were killed, a breach was made in the walls. In a final assault the Mexicans overpowered and slaughtered the garrison in a hand-to-hand struggle in the chapel, the five survivors being subsequently killed in cold blood by order of Santa Anna. "Remember the Alamo" became the war-cry of the Texans, who, under Sam Houston, at San Jacinto, on April 21, 1836, defeated and captured Santa Anna. In 1883 the Alamo building was bought by the State and preserved as a public monument, and in 1913 the city of San Antonio began its restoration.

See A. M. Williams, *Sam Houston and the War of Independence in Texas* (Boston, 1893); Zavola, *Story of the Siege and Fall of the Alamo* (San Antonio, 1911).

ÅLAND ISLANDS, an archipelago at the entrance to the Gulf of Bothnia, about 25m. from the coast of Sweden, and 15m. from that of Finland. Area 551sq.m., with a population of 27,180 in 1925. The group which forms the Finnish department of Åland (Åhvenanmaa), consists of nearly 300 islands, of which about 80 are inhabited, the remainder being desolate rocks. These islands form a continuation of a dangerous granite reef extending along the south coast of Finland. They formerly belonged to Sweden, and in the neighbourhood the first victory of the Russian fleet over the Swedes was gained by Peter the Great in 1714. They were ceded to Russia in 1809, and remained Russian until 1917, when Finland was proclaimed an independent and sovereign State. The population centres chiefly in the island of Åland, upon which is situated the small town of Mariehamn. The inhabitants, hardy seamen and fishermen, are mostly of Swedish descent. The surface of the islands is generally sandy, the soil thin and the climate keen; yet Scotch fir, spruce and birch are grown; and rye, barley, flax and vegetables are produced. Great numbers of cattle are reared; and cheese, butter and hides, as well as salted meat and fish, are exported. There are several excellent harbours (notably that of Ytterläs), which were of great importance to Russia from the fact that they are frozen up for a much briefer period than those on the coast of Finland.

History.—When, by an article of the Treaty of Fredrikshavn (Friedrichshamn), Sept. 5-17, 1809, the islands were ceded to Russia, together with the territories forming the grand-duchy of Finland on the mainland, the Swedes were unable to secure a provision that the islands, occupying a position of great strategic importance in relation to the entrance to Stockholm and to the Gulf of Bothnia, should not be fortified. The question was a vital one for Great Britain's trade as well. In 1854, accordingly, during the Crimean War, an Anglo-French force destroyed the fortress of Bomarsund. By the "Åland Convention," between Great Britain, France and Russia on March 30, 1856, it was stipulated that "the Åland islands shall not be fortified, and that no military or naval establishments shall be maintained or created on them." By the 33rd article of the Treaty of Paris (1856) this convention, annexed to the final act, was given "the same force and validity as if it formed part thereof." In 1906 it was asserted that Russia, under pretext of stopping the smuggling of arms into Finland, was massing considerable forces at the islands. The question of the Åland islands created discussion in 1907 and 1908 in connection with new North sea agreements, and Russia considered the 1856 convention rather humiliating. But it was plainly shown by other powers that they did not propose to regard it as open to question, and the point was not officially raised.

Under the tsardom the islands were united with Finland until the latter country declared her independence in 1917. In Dec. 1917, the Åland islanders claimed the right of self-determination on their own account, and unofficial plebiscites showed a vote in favour of reunion with Sweden. Finland granted the islands autonomy on May 7, 1920, but refused to contemplate their secession. In June the leaders of the secession movement were

Mexico, returned to Spain and occupied a small post under the Council of the Indies. His plays were published in 1628 and 1634; the most famous of these is *La Verdad sospechosa*, which was adapted by Corneille as the *Menteur*. Alarcon was pre-occupied with ethical aims, and his gift of dramatic presentation was as brilliant as his dialogue was natural and vivacious. It has been alleged that his foreign origin is noticeable in his plays, but in *El Tejedor de Segovia* he had produced a masterpiece of national art, national sentiment and national expression.

ALARCON, PEDRO ANTONIO (1833-1891), Spanish writer, was born at Guadix March 10 1833. He had a considerable reputation as a journalist and poet when his play, *El Hijo pródigo*, was hissed off the stage in 1857. The failure exasperated Alarcon so much that he enlisted under O'Donnell as a volunteer in the Moroccan campaign. The expedition provided the material for the brilliant *Diario de un testigo de la guerra de Africa* (1859), a masterpiece in its way as a description of campaigning life. On his return from Morocco, Alarcon did great service to the liberal cause as editor of *La Política*. But in the years 1868-74 he ruined his political reputation by a series of rapid changes of front. His literary reputation steadily increased, however. *El sombrero de tres picos* (1874), a clever resetting of an old Spanish tale, lives for its malicious wit and minute observation. His other works include *Cuentos amorios* (1881); *Historietas nacionales* (1881); *El Escandalo* (1875); *El Capitan Veneno* (1881). Alarcon died July 20, 1891.

ALARD, JEAN DELPHIN (1815-1888), famous French violinist and teacher, was professor at the Paris Conservatoire from 1843 to 1875. Sarasate was one of his pupils.

ALARIC (c. 370-410), Gothic conqueror, the first Teutonic leader who stood as a conqueror in the city of Rome, was probably born about 370 on an island named Peucè (the fir) at the mouth of the Danube. He was of noble descent, his father being a scion of the family of the Balthei or Bold-men, next in dignity among Gothic warriors to the Amals. He was a Goth and belonged to the western branch of that nation (sometimes called the Visigoths) who at the time of his birth were quartered in the region now known as Bulgaria, having taken refuge on the southern shore of the Danube from the pursuit of their enemies the Huns.

In the year 394 he served as a general of *foederati* (Gothic irregulars) under the Emperor Theodosius in the campaign in which he crushed the usurper Eugenius. As the battle which terminated this campaign, the battle of the Frigidus, was fought near the passes of the Julian Alps, Alaric probably learnt at this time the weakness of the natural defences of Italy on her north-eastern frontier.

In the shifting of offices which took place at the beginning of the reigns of Arcadius and Honorius, the sons of Theodosius, Alaric apparently hoped that he would receive one of the great war ministries of the empire, and thus instead of being a mere commander of irregulars would have under his orders a large part of the imperial legions. This, however, was denied him, and he remained an officer of *foederati*. His disappointed ambition prompted him to take the step for which his countrymen were longing, for they too were grumbling at the withdrawal of the "presents," in other words the veiled ransom-money, which for many years they had been accustomed to receive. They raised him on a shield and acclaimed him as a king; leader and followers both resolved (says Jordanes, the Gothic historian) "rather to seek new kingdoms by their own labour, than to slumber in peaceful subjection to the rule of others."

Alaric struck first at the eastern empire. He marched to the neighbourhood of Constantinople, but finding himself unable to undertake the siege of the city, he retraced his steps westward and marched southward through Thessaly and the unguarded pass of Thermopylae into Greece. Alaric's invasion of Greece lasted two years (395-96); he ravaged Attica but spared Athens, which at once capitulated to the conqueror, and penetrated into Peloponnesus, capturing its most famous cities, Corinth, Argos and Sparta, selling many of their inhabitants into slavery. Here, however, his victorious career ended. Stilicho, who had come a second time to the assistance of Arcadius, succeeded in shutting up the Goths in

the mountains of Pholoe on the borders of Elis and Arcadia. Alaric escaped with difficulty, and not without some suspicion of connivance on the part of Stilicho. He crossed the Corinthian gulf and marched with the plunder of Greece northwards to Epirus.

Next came an astounding transformation. For some mysterious reason, probably connected with the increasing estrangement between the two sections of the empire, the ministers of Arcadius conferred upon Alaric the government of part of the important prefecture of Illyricum. Here, ruling the Danubian provinces, he was on the confines of the two empires, and, in the words of the poet Claudian, he "sold his alternate oaths to either throne," and made the imperial arsenals prepare the weapons with which to arm his Gothic followers for the next campaign. It was probably in the year 400 that Alaric made his first invasion of Italy, co-operating with another Gothic chieftain named Radagaisus. After spreading desolation through north Italy, and striking terror into the citizens of Rome, Alaric was met by Stilicho at Pollentia (a Roman municipality in what is now Piedmont). The battle (April 6, 402, Easter day) was a victory, though a costly one, for Rome and effectually barred the further progress of the barbarians. Alaric was an Arian Christian who trusted to the sanctity of Easter for immunity from attack, and the enemies of Stilicho reproached him for having gained his victory by taking an unfair advantage of the great Christian festival. The wife of Alaric is said to have been taken prisoner after this battle; and there is some reason to suppose that he was hampered in his movements by the presence with his forces of large numbers of women and children, having given to his invasion of Italy the character of a national migration. After another defeat before Verona, Alaric quitted Italy, probably in 403.

He had not indeed reached Rome, but his invasion of Italy had produced important results. It had caused the imperial residence to be transferred from Milan to Ravenna, it had necessitated the withdrawal of the 20th legion from Britain, and it had probably facilitated the great invasion of Vandals, Suevi, and Alani into Gaul, by which that province and Spain were lost to the empire. We next hear of Alaric as the friend and ally of his late opponent Stilicho. The estrangement between the eastern and western courts had in 407 become so bitter as to threaten civil war, and Stilicho was actually proposing to use the arms of Alaric in order to enforce the claims of Honorius to the prefecture of Illyricum. The death of Arcadius in May 408 caused milder counsels to prevail in the western cabinet, but Alaric, who had actually entered Epirus, demanded that if he were thus suddenly bidden to desist from war, he should be paid handsomely for what in modern language would be called the expenses of mobilization. The sum which he named was a large one. 4,000 pounds of gold (about £160,000 sterling), but under strong pressure from Stilicho the Roman senate consented to promise its payment.

Three months later Stilicho himself and the chief ministers of his party were treacherously slain in pursuance of an order extracted from the timid and jealous Honorius; and in the disturbances which followed the wives and children of the barbarian *foederati* throughout Italy were slain. The natural consequence was that these men to the number of 30,000 flocked to the camp of Alaric, clamouring to be led against their cowardly enemies. He accordingly crossed the Julian Alps, and in Sept. 408 stood before the walls of Rome (now with no capable general like Stilicho to defend her) and began a strict blockade.

No blood was shed this time; hunger was the weapon on which Alaric relied. When the ambassadors of the senate in treating for peace tried to terrify him with their hints of what the despairing citizens might accomplish, he gave with a laugh his celebrated answer, "The thicker the hay, the easier mowed!" After much bargaining, the famine-stricken citizens agreed to pay a ransom of more than a quarter of a million sterling, besides precious garments of silk and leather and three thousand pounds of pepper. Thus ended Alaric's first siege of Rome. At this time, and indeed throughout his career, the one dominant idea of Alaric was not to pull down the fabric of the empire but to secure for himself, by negotiation with its rulers, a regular and recognized position within its borders. His demands were certainly large—the concession of

a block of territory 200 m. long by 150 wide between the Danube and the Gulf of Venice (to be held probably on some terms of nominal dependence on the empire), and the title of commander-in-chief of the imperial army. As all attempts to conduct a satisfactory negotiation with this emperor failed, Alaric, after instituting a second siege and blockade of Rome in 409, came to terms with the senate, and with their consent set up a rival emperor and invested the prefect of the city, a Greek named Attalus, with the diadem and the purple robe. But Attalus rejected the advice of Alaric and lost in consequence the province of Africa, the granary of Rome, which was defended by the partisans of Honorius. The weapon of famine, formerly in the hand of Alaric, was thus turned against him, and loud in consequence were the murmurs of the Roman populace. Honorius was also greatly strengthened by the arrival of six legions sent from Constantinople to his assistance by his nephew Theodosius II. Alaric therefore cashiered his puppet emperor Attalus after 11 months of ineffectual rule, and once more tried to reopen negotiations with Honorius. These negotiations would probably have succeeded but for the malign influence of another Goth, Sarus, the hereditary enemy of Alaric and his house. When Alaric found himself once more outwitted, he marched southward and began in deadly earnest his third siege of Rome. No defence apparently was possible; there are hints, not well substantiated, of treachery; there is greater probability of surprise. However this may be (for our information at this point of the story is miserably meagre) on Aug. 24 410, Alaric and his Goths burst in by the Salarian Gate on the north-east of the city. The Goths showed themselves not absolutely ruthless conquerors, and there is no reason to attribute any extensive destruction of the buildings of the city to Alaric and his army. Contemporary ecclesiastics recorded with wonder many instances of their clemency: the Christian churches saved from ravage; protection granted to vast multitudes both of pagans and Christians who took refuge therein; vessels of gold and silver, which were found in a private dwelling, spared because they "belonged to St. Peter"; at least one case in which a beautiful Roman matron appealed, not in vain, to the better feelings of the Gothic soldier who had assailed her.

Alaric then marched southwards into Calabria. He desired to invade Africa, which on account of its corn crops was now the key of the position; but his ships were dashed to pieces by a storm in which many of his soldiers perished. He died soon after, probably of fever, and his body was buried under the river-bed of the Busento, the stream being temporarily turned aside from its course while the grave was dug wherein the Gothic chief and some of his most precious spoils were interred. When the work was finished the river was turned back into its usual channel, and the captives by whose hands the labour had been accomplished were put to death that none might learn their secret. He was succeeded in the command of the Gothic army by his brother-in-law, Ataulphus.

Our chief authorities for the career of Alaric are the historian Orosius and the poet Claudian, both strictly contemporary; Zosimus, a somewhat prejudiced heathen historian, who lived probably about half a century after the death of Alaric; and Jordanes, a Goth who wrote the history of his nation in the year 551, basing his work on the earlier history of Cassiodorus (now lost), which was written c. 520.

(T. H.; X.)

ALARIC II. (d. 507), eighth king of the Goths in Spain, succeeded his father Euric, or Evaric, on Dec. 28, 484. His dominions not only included the whole of Spain except its north-western corner, but also Aquitaine and the greater part of Provence. In religion Alaric was an Arian, but he greatly mitigated the persecuting policy of his father, Euric, towards the Catholics and authorized them to hold, in 506, the council of Agde. He appointed a commission to prepare an abstract of the Roman laws and imperial decrees, which should form the authoritative code for his Roman subjects. This is generally known as the *Breviarium Alaricianum*, or *Breviary of Alaric* (q.v.). Alaric endeavoured strictly to maintain the treaty which his father had concluded with the Franks, but Clovis found a pretext for war in the Arianism of Alaric. The two armies met in 507 at the Campus Vogladensis, near Poitiers, where the Goths were defeated, and their king, who took to flight, was overtaken and slain, it is said, by Clovis himself. This battle ended the rule of the Visigoths in Gaul.

ALA-SHEHR (anc. PHILADELPHIA), Aidin vilayet, Asia Minor, in the Kuzu Chai valley (*Cogamus*), at the foot of the Boz Dagħ (Mt. Tmolus) 83 m. east of Smyrna (105 by railway). Pop. (1927) 32,801. Philadelphia was founded by Attalus II. of Pergamum about 150 B.C., became one of the "Seven Churches" of Asia, and was called "Little Athens" on account of its festivals and temples. It was subject to frequent earthquakes. Philadelphia was an independent neutral city, under the Latin Knights of Rhodes, when taken in 1390 by Sultan Bayezid I. and an auxiliary Christian force under the emperor, Manuel II., after a long resistance, when all other cities of Asia Minor had surrendered. Twelve years later it was captured by Timur, who built a wall with the corpses of his prisoners. A fragment of the ghastly structure is in the library of Lincoln cathedral. The town is connected by railway with Afium Qarahisar and Smyrna. It is ill-built, but, as it stands above the wide fertile Hermus plain, the distant view is imposing. There are small industries and a fair trade. A mineral spring yields a heavily charged water, "Eau de Vals," in great request in Smyrna.

See W. M. Ramsay, *Letters to the Seven Churches* (1904).

ALAS, LEOPOLDO (1852-1901), Spanish novelist and critic, was born at Zamora. His reputation rests on his psychological novel, *La Regenta* (1884-85), whose scene is laid in Oviedo. The ruthless analysis of its characters gives it a place among the best novels of the period.

ALASKA, formerly called Russian America, is a Territory of the United States of America, occupying the extreme north-western part of North America and including the adjacent islands. The name is a corruption of a native word possibly meaning "mainland" or "peninsula." The Territory of Alaska comprises, first, all that part of the continent west of the 141st meridian; secondly, the eastern Diomed Island in Bering Strait, and all islands in Bering Sea and the Aleutian chain lying east of a line drawn from the Diomedes to pass midway between Copper Island, off Kamchatka, and Attu Island of the Aleutians; thirdly, a narrow strip of coast and adjacent islands north of a line drawn from Cape Muzon, in latitude 54° 40' N., up Portland canal to its head, and thence, following the summit of the mountains situated parallel to the coast to the 141st meridian, provided that when the line runs more than ten marine leagues from the ocean the limit shall be formed by a line parallel to the windings of the coast and which shall never exceed the distance of ten marine leagues therefrom. Alaska is bounded on the north by the Arctic ocean, on the west by the Arctic ocean, Bering Sea and Bering Strait, on the south and south-west by the Gulf of Alaska and the Pacific ocean, and on the east by British Columbia and Yukon territory. The total area of Alaska is 590,884 sq. m., an area equal to nearly one-fifth that of continental United States or more than twice the size of Texas, the largest State of the Union.

A RAVEN TOTEM POLE
Totem poles are erected by the Alaskan Indians to the animal from which they think their tribe has descended

Principal Physical Features.—As indicated by the above boundaries, Alaska is of straggling, irregular shape, extending in longitude from about 130° W. to 193° W. or 167° E., as specified in the articles of cession and through more than 20° of latitude, 51° to 71° 25' N. The southern limit lies far out in the Pacific as part of the Aleutian island chain, only 2° north of the boundary between the western half of the United States and Canada. Alaska consists of a compact central mass and two straggling appendages running from its south-western and south-eastern corners. These three parts will be referred to hereafter respectively, as continental Alaska, Aleutian Alaska, and the "Panhandle."

The general ocean coast-line is about 4,750 m. and including the islands, bays, inlets and rivers to the head of tide water, is about

FISHING AND MINING IN ALASKA

Salmon fishing ranks first among Alaskan industries to-day. Another interest that has attracted much capital to that part of the world is mining, developed rapidly during the last 25 years but leaving much territory still to be exploited, particularly in the coal districts. It is interesting to note that, whereas the United States purchase price of the Territory of Alaska in 1867 was \$7,200,000, the estimated total output of the fisheries and mines alone for the period 1867-1927 exceeded \$120,000,000

26,000m. in length. The entire southern coast is very precipitous, much indented by deep fiords, with only slight stretches of beach or plain. Its elevation gradually decreases as one travels west toward the Aleutians. A great submarine platform extends throughout a large part of Bering Sea. The western and northern coasts are regular in outline with long straight beaches; and shallows are common in the seas that wash them.

Of the vast number of islands within the boundaries of Alaska and constituting part of its territory, only a few of the more important can be mentioned in the scope of this article. At the south-eastern extremity and lying close inland, is the Alexander Archipelago (*q.v.*) consisting of some 1,100 islands, large and small. South-west of the Alaska Peninsula there are two groups. (1) Kodiak—the largest island, of the same name, is 40m. by 100m., and may be considered a continuation of the Kenai Peninsula. The group's western continuation consists of the Semidi, Shumagin and Sannak clusters. (2) The Aleutian islands (*q.v.*), sweeping 1,200m. or more west-south-west from the end of Alaska peninsula; west of the mainland in Bering Sea, the Pribilof islands, about 500m. south of Cape Prince of Wales, the small Hall and St. Matthew Islands; to the north toward Bering Strait, the large St. Lawrence Island, with Nunivak near the coast to the south-east. Of the smaller islands, within Bering Sea, only the Pribilofs (home of the fur seal during breeding season) are of special interest or value.

Alaska has mountains, plateaux and lowlands on a grand scale. "In a broad way, the larger features of topography correspond with those of the western States. There is a Pacific mountain system, a central plateau region, a Rocky mountain system, and a Great plains region. These four divisions are well marked, and show the close geographic relation of this area to the southern part of the continent." The orographic features of the Pacific mountain system trend parallel to the coast-line of the Gulf of Alaska. The Pacific mountain system includes four ranges. The coast range of the Panhandle attains a width of 100m., but has no well-defined crest line. The range is characterized by the uniformity of summit levels between 5,000 and 6,000 feet. Continuing the coast range, with which it is closely associated—the Chilkat river lies between them—is the St. Elias Range (a term now used to include not only the mountains between Cross Sound and Mt. St. Elias but the Chugach, Wrangell and Nutzotin mountains), lying in the south-east of the main peninsula or continental Alaska. Among its principal peaks are: Mt. Crillon, Mt. Fairweather and Mt. Vancouver, all above 15,000ft. and Mt. Wrangell, 17,500ft. (an active volcano); in the Nutzotin mountains, Mt. St. Elias, 18,024ft., and in Canadian territory, Mt. Logan, 19,539 feet. The Aleutian range, of which crest the Aleutian islands are remnants, fills out the system near the coast. In the Aleutian range, near the base of the Alaska peninsula, there occurred in the early days of June 1912, one of the great volcanic eruptions of historic times. The top of Katmai, a mountain showing no evidence theretofore of volcanic action, was entirely blown off, and about the same time, there came into existence in the valley to the north-west, a vast number of tiny volcanic vents or fumaroles and since known as the valley of the "Ten Thousand Smokes." The mountain and valley have since been set apart by proclamation of the president (Sept. 24, 1918) as the "Katmai National Monument." The Alaska range, which lies south of the Yukon drainage system, connects with the Nutzotin and Skolai branches of the St. Elias Range. It is splendidly marked by many snowy peaks, including Mt. Foraker (17,000ft.) and Mt. McKinley (20,300ft.), the loftiest peak in North America. North of the Yukon are the Baird Mountains and the Endicott Range, an eastward extension of the Rocky mountains. Between the Pacific mountains and the last mentioned ranges lies the vast central plateau region or Yukon plateau. Finally, between the Endicott Range and the Arctic ocean is the Arctic slope region, a sloping plain corresponding somewhat to the interior plains of the United States.

The glaciers of the Panhandle and throughout the rest of the Pacific region are most remarkable—unusual, alike for their number and size. Thousands of Alpine glaciers from 1 to 15m.

long fill the upper valleys and canyons of the mountains. Other glaciers are of the Piedmont type. The two most notable glaciers are the Malaspina, largest in the Territory, extending for 50m. along the seaward base of Mt. Elias; and the Muir, at the head of the icy straits. The Muir was much visited by tourists prior to the earthquake in 1899, which so shattered the glacier and increased the discharge of ice that steamers no longer find it safe to approach near the face. The condition of the glaciers of Alaska,

generally speaking, appears at this time to be one of recession; many of them now have terminal moraines many miles back.

Chief among the streams of Alaska is the Yukon, more than 2,000m. in length, which practically bisects the main peninsula. The principal feeders of this great river have their sources far away to the south-east in the coastal mountains along the boundary between Alaska, British Columbia and the Canadian Yukon territory. It flows in a general north-westerly direction for about one half its length, passing through a small section of

TWO SQUARES SHOWING THE RELATIVE AMOUNT OF SPACE AVAILABLE PER PERSON IN ALASKA (107 SQ. M.) AND IN CONTINENTAL UNITED STATES (18 ACRES)

British Columbia and through territory of the "Canadian Yukon" till it reaches the 141st meridian. Here it enters American territory and, continuing to the north-westward, passes within the Arctic Circle for a short distance in the vicinity of Ft. Yukon. It then turns south-westerly, gathering volume from many tributaries, the principal of which are the Tanana and the Koyukuk, and finally empties its flood into Bering Sea through many mouths and over a vast bar, in longitude (approx.) 164° W. and latitude 63° N. The ocean port for the river, where merchandise is transferred by lighterage from ocean vessels to river boats, is a bay on St. Michael island, lying about 60m. to the north-east of the Northern or Apoon mouth. River boats, drawing from three and a half to four feet can enter the Apoon mouth and proceed without difficulty, in ordinary stages of water, practically the whole length of the river to White Horse, connecting there with the White pass and Yukon railway to Skagway. The period of navigation on the Yukon is from four to four and a half months. The second largest river in Alaska is the Kuskokwim, with its sources in the mountains of the Alaska range south of the Yukon drainage basin, and emptying into the Bering Sea about 150m. south of the mouth of the Yukon. It is navigable for about 600 miles. Out of the Alaska and Nutzotin mountains two great rivers flow southward: the Copper, practically unnavigable except for small boats, because of its turbulence and the discharge of glaciers into its waters; and the Susitna, also practically unnavigable. Both of these rivers have their sources in lofty mountain masses, and are swift and powerful streams carrying with them much silt.

The Panhandle is remarkably picturesque. The maze of islands of the Alexander Archipelago, hundreds in number, are remnants of a submerged mountain system; the islands rise 3,000 to 5,000ft. above the sea, with luxuriantly wooded tops and bold, sheer sides scarred with marks of glacial action. Through the inner channels, sheltered from the Pacific by the island rampart, runs the "inland passage," the tourist route northward from Seattle, Wash. The inter-insular straits are carried up into the mainland shore as fiords heading in rivers and glaciers. Most remarkable are the inlets known as Portland canal and Lynn canal (continuing Chatham Strait). The first is very deep, with precipitous shores and bordering mountains 5,000 to 6,000ft. high; the second is a noble fiord 100m. long and on an average 6m. wide, with magnificent Alpine scenery.

Continental Alaska in the interior is essentially a vast plateau. "The traveller between the main drainage areas of the interior is struck by the uniform elevation. Rounded hills, level meads, and persistent flat-topped ridges, composed of rocks of varying

structure, rise to about the same level and give the impression that they are the remnants of a former continuous surface. In height it varies from about 5,000ft. close to the bases of the mountain systems to less than 3,000ft. in the vicinity of the main lines of drainage and slopes gradually toward the north."

Geology.—The outstanding features of Alaska are its mountain ranges, most of which consist of closely folded and contorted beds of sedimentary rock and underlying igneous masses, by intrusion of which the sedimentary beds were uplifted. A notable mountain chain is the Alaska range, which is nearly 600m. long and 50 to 80m. wide. This range, which was elevated to its present height late in Tertiary time, marks an old line of movement that has repeatedly been the site of folding and mountain building. In this range is the Mt. McKinley National Park, a reservation that contains 2,600sq.m. and includes the highest peak in North America, Mt. McKinley, which stands 20,300ft. above sea-level. Volcanic products, which were poured out at intervals during an immensely long time, form a part of some ranges and make up most of the mass of many peaks. Among these volcanic peaks are the Wrangell mountains and many of the mountains on Alaska peninsula and in the Aleutian chain of islands. On the other hand, Mt. McKinley and Mt. St. Elias consist of masses of intruded granitic rock surrounded by sedimentary beds. The high relief of the larger mountain masses is due to their relatively recent elevation, the forces of erosion not yet having had time greatly to reduce their height.

The general outline of the mountain ranges in Alaska is a continuation of that seen in the region to the south, in Canada, but the course of the ranges in Alaska swings around from north-west to south-west, toward Asia, and the geologic history of the coastal ranges in both continents is doubtless similar. Far to the north lies Brooks range, from the northern base of which runs a series of gently folded beds that extend to the Arctic ocean.

The details of the geological structure and of the petrology of Alaska are extremely complex, and the attempt to trace the geological history of the region is very difficult. The geological record indicates a long series of periods of uplift and depression, of erosion and deposition, of folding and faulting and metamorphism of the beds deposited, and of intermittent volcanism that produced great areas of lava and ashes, which, like all other deposits, were shifted here and there and at some places greatly altered.

The oldest sedimentary deposits are certain pre-Cambrian rocks that lie in a broad belt in the upper Yukon valley, especially in the region between the Yukon and the Tanana, where they include what is called the Birch Creek schist, the bed rock in that region. The conditions and events in early Cambrian time are unknown, but in late Cambrian and in parts of Ordovician time large areas in Alaska appear to have been submerged, for most of the beds formed during those periods are marine deposits. Evidences of emergence, however, are found at some places. In early Devonian time there was a period of elevation, deformation, and subsidence over large areas. Toward the end of the Carboniferous period, in late Pennsylvanian or early Permian time, marine deposition prevailed, perhaps intermittently, until beds of limestone that measured in the aggregate thousands of feet in thickness were laid down over parts of Alaska. The Palaeozoic beds include at many places accumulations of volcanic material, but the greatest eruptions in Palaeozoic time appear to have occurred intermittently near its end, during the Pennsylvanian and Permian epochs. Most of the products of these eruptions lie south of the Alaska range. In late Permian and early and middle Triassic time Alaska was a land surface undergoing erosion. In late Triassic time depression again brought the sea over a large part of Alaska. This submergence was followed by widely extended uplift, which included probably all of Alaska. In early Jurassic time the Pacific and Arctic coasts were submerged and along them were deposited beds of sandstone, shale and limestone. Middle Jurassic deposits cover a somewhat wider area along the Pacific coast. In Jurassic time there was a persistent shore line near the site of the Alaska range.

In early Cretaceous (lower Cretaceous) time renewed submergence brought the sea over much of Alaska, including parts of

the Yukon valley, most of which had been above the sea since the end of Palaeozoic time. A large part of northern Alaska, which had been land since the end of the Triassic period, was also submerged. The deposits of this time include a basal conglomerate and overlying shale and limestone. An uplift and a change in places of sedimentation followed, in later Cretaceous (upper Cretaceous) time, during which the larger topographic features of present Alaska were doubtless outlined. Marine deposits were laid down along the Arctic and Pacific coasts and in the lower and broader parts of the Yukon and probably other valleys. Terrestrial deposits were formed in embayments that stood on the sites of the larger river valleys. The submergence of the Yukon valley gradually increased and as gradually slackened, and swamps were formed in which plants grew and coal beds were laid down. The Cretaceous deposits in the Kuskokwim valley appears to be very similar to those in the lower Yukon valley. While sedimentation was in progress in the Yukon valley the rest of Alaska may have been land. During later Cretaceous time the sea invaded the sites of the Matanuska and Chitina valleys and parts of the southern coastal region. The deposits of this time in Alaska peninsula include marine shale, coal-bearing shale, conglomerate sandstone and shale, probably of mixed marine and terrestrial origin. The end of Cretaceous time on Alaska peninsula appears to have been marked by a period of mountain growth. The Cretaceous beds are greatly folded everywhere and many of them are cut by intrusive rocks and intrusive veins. Deposits of tuff laid down in early Tertiary (Eocene) time show that the diastrophic movements which began late in Cretaceous time culminated in volcanic eruptions. Among the earliest post-Cretaceous deposits are the Tertiary coal-bearing beds. Two groups of coal beds that lie near the Alaska range are reached by the Alaska Railroad, one in the valley of Matanuska river, in lat. $61^{\circ} 45'$, the other along and east of the Nenana river, about lat. 64° . Most of the coal mined is used on the railroad. Beds of lignitic coal are exposed at many places around Cook Inlet and in the lower part of the valley of the Susitna river. The coal-bearing beds, which have been at some places greatly tilted and folded, generally consist of poorly consolidated sand, clay and gravel, and at some places contain abundant remains of plants. Many of the Tertiary rocks, however, consist of hard conglomerate and shale, and include basaltic lava and other volcanic material, as well as intrusive dikes and sills.

By early Quaternary time the great mountain-building movements in the south of the Alaska range had apparently ceased and the larger topographic features of this region, including the Kenai-Chugatch range, the Talkeetna Mountains and the Yukon-Tanana upland, had assumed nearly their present form, although the details of the drainage may have been different, for the climate was milder than it is now. A colder age followed, in which enormous glaciers were formed in the mountains. The Quaternary beds, which include glacial deposits, are widespread. In the Alaska range and in the region south of it such deposits constitute a large part of the unconsolidated surface material. The glaciers abraded the rocks of the highlands and carried down into the lowlands immense quantities of gravel, sand, silt and till, modifying the forms of the higher valleys and leaving thick deposits over large areas. The bluffs along Copper river, for example, consist of glacial deposits more than 500ft. thick; and moraines, outwash gravel and thick delta fans made up of glacial material cover large areas. The glaciers now appear to be receding, but the deposition of outwash from glaciers is still in active progress at many places, and the great glaciers in the Alaska range and the Wrangell mountains, and especially the glaciers of Kenai Peninsula, Prince William Sound and the coast farther south, are conspicuous features. The higher parts of the Alaska range are the gathering grounds for some of the largest valley glaciers. Five or more of these great tongues of ice are from 2 to 4m. wide and 30 to 50m. long. The present surface form of the mountains of this range has been produced in large part by the erosive action of these glaciers and of their much larger predecessors.

Great changes in the climate of north-western North America are indicated by the fossil plants. The flora of Alaska was at times evidently that of a temperate or a warmer region.

The uplifts in Alaska apparently established land connection between North America and Asia at several periods. Across this body of land in Tertiary time horses of early types passed to Asia from the central plains of North America, which appear to have been the first habitat of the horse. Early elephants, or elephant-like creatures, on the other hand, found their way from Asia to America, where their remains have been discovered at many places.

Climate.—Alaska is one of the “ends of the earth” and as such presents many interesting extremes, none more than in its cli-

GRAPH CONTRASTING THE CLIMATIC CONDITIONS OF ALASKA
The curves show the monthly mean temperatures at Ketchikan, on the south-east coast, Nome, on Bering Sea, and Rampart, in the interior on the Yukon river. The columns show the normal annual precipitation at these three places

matic features. Enclosed on the north and west by Arctic waters, and from the Alaska peninsula down the long coast to the south-eastward by north Pacific waters, with their tempering currents drifting eastward encompassing the islands of the Aleutian group and those farther south, there results a great variation in temperature and precipitation. The climate of the Aleutians is oceanic, with moderate and fairly uniform temperatures, much rain and almost constant fogs. The summers are cooler than along the coast to the east and southward, and the winters milder, with much less snow, never going as low as zero. Clouds laden with moisture from the warm Pacific currents, being swept in upon the mountains and the many glaciers by the prevailing winds, produce a heavy precipitation of rain in summer and snow in winter. Crossing the coast range to the interior, one encounters an entirely different climate. Here the precipitation is comparatively light, both of rain and snow, except upon the high mountain ranges. Low temperatures occur in winter—occasionally as low as -75° or -80° F—with short, hot summers. In this part of Alaska, the ground is permanently frozen to great depth in most of the valleys, but on the drier hillside slopes, it frequently happens that but little frost is found. The tempering influence of the ocean currents practically disappears north of the line of the Pribilof islands, or about the middle of Bering Sea, and the regions to the northward and eastward of this are for the most part barren, windswept and inhospitable. Arctic conditions prevail, especially beyond Bering Strait. Point Barrow, farthest north (71° plus), is ice-locked for about ten months of the year.

Fauna and Flora.—The fauna of Alaska is very rich and surprisingly varied. The lists of insects, birds and mammals are especially noteworthy. Of these three classes, and of other than purely zoological interest, are mosquitoes, which swarm in summer in the interior in vast numbers; sea fowl, which are remarkably abundant near the Aleutians; moose, and especially caribou, which in the past were very numerous in the interior and of extreme economic importance to the natives. The destruction of the wild caribou threatened to expose the Indians to wholesale starvation, hence the effort which the United States Government made to stock the country with domestic reindeer from Siberia. It is, however, the fish and fur-bearing animals of its rivers and

surrounding seas that are economically most distinctive of and important to Alaska. The fishing grounds extend along the coast from the extreme south-east past the Aleutians into Bristol Bay.

Herring, cod and salmon abound in almost incredible numbers. Of marine mammals, whales are hunted far to the north in Bering Sea and the Arctic ocean, but are much less common than formerly as are also the walrus, the sea-otter and the fur seal. There are half a dozen species of hair seals and sea-lions. The number of fur-bearing land animals is equally large. Sable, ermine, wolverines, minks, land-otters, beavers and musk-rats have always been important items in the fur trade. There are black, grizzly and polar bears, and also two exclusively Alaskan species, the Kodiak and the glacier bear. The grey wolf is common; it is the basal stock of the Alaskan sledge-dog. The red fox is widely distributed, and the white or Arctic fox is very common along the eastern coast of Bering Sea. A blue fox, once wild, is now domesticated on Kodiak and the Aleutians, and on the southern continental coast, and a black fox, very rare, occurs in south-eastern Alaska. The silver fox is very rare.

The Alaskan flora is less varied than the fauna. The forests of the coastal region eastward from Cook Inlet, and particularly in south-eastern Alaska, are of fair variety and of great richness and value. The balsam fir and in the south the red cedar occur in scant quantities; more widely distributed, but growing only under marked local conditions, is the yellow or Alaska cedar, a very hard and durable wood of fine grain and pleasant odour. Far the most abundant are coast and Alpine hemlocks and the tideland or Sitka spruce. The spruce is not confined to this part of Alaska, but is the characteristic and universal tree. The separation of the coast and interior flora is almost complete; only along the mountain passes and river valleys, and rarely there, is there any change of species. Timber, however, is fairly abundant along the entire course of the Yukon above Anvik (about 400m. from the mouth), along the great tributaries of the Yukon and along every stream in central Alaska. The woods of the interior consist almost entirely of spruce. On the Yukon flats it grows in a vast forest impenetrably dense. The timber line, which in the Panhandle and along the southern coast of the continental mass runs from 1,800 to 2,400ft., frequently rises in the interior plateau even to 4,000 feet. Next in importance after spruce, in the interior, is birch and then balsam poplar. Thickets of alders and willows in wet places and new-made land, aspens and large cottonwoods west of the characteristic spruce area (as on Seward Peninsula), are also common. Toward the Arctic Circle, the timber becomes, of course, sparse, low, gnarled and distorted. The willows in the Arctic drainage basin shrink to shrubs scarcely knee-high. Grasses grow luxuriantly in the river bottom and wherever the tundra moss is destroyed to give them footing. Most distinctive is the ubiquitous carpeting of mosses, varying in colours from the pure white and cream of the reindeer moss to the deep green and brown of the peat moss, all conspicuously spangled in the brief summer with bright flowers of the higher orders, heavy blossoms on stunted stalks.

Sedges available for forage grow in the tundra. In August berries are fairly abundant over the interior; one of them, the salmon or cloud berry, preserved in seal oil for the winter, is an important food of the natives. The western timber limit is on Kodiak island. The Aleutian islands are almost destitute of trees, but are covered with a luxuriant growth of herbage. Climatic differences cannot account for the treeless condition of the country west of this point, and the true explanation lies probably in the fact that in winter, when the seeds of the coastal forests ripen and are released, the prevalent winds west of Kodiak are damp and blow from the south and south-west, while the spread of the seeds requires dry winds blowing from the north and north-west. Such favourable conditions occur only rarely.

Population.—The population in 1867, at the time of the cession from Russia, was estimated at 30,000, of which two-thirds were Eskimos and other natives. The population at the various decennial censuses was as follows: 33,426 in 1880; 32,052 in 1890; 63,592 in 1900, of whom approximately 48% were whites, 46% natives and 6% Japanese and Chinese; 64,356 in 1910; and

55,036 in 1920, a decrease of 14.5% since 1910. The whites numbered 29,000, the Indians and Eskimos 25,000. The population in 1930 was 59,278 by Federal census. The white population of Alaska steadily increased until 1915, when it exceeded 40,000. Subsequent losses were due to: (1) enrolment in military service of about 3,500 men, few of whom returned; (2) high wages in the United States; and (3) the decrease in the gold-mining industry. The upward curve in population was not restored until 1924. In that year the number of people arriving in the Territory exceeded the number departing by 577. In addition to the permanent residents of Alaska, between 25,000 and 30,000 men annually visit the Territory to find employment in fishing and mining. The permanent or stabilized white population is found mostly in towns or larger mining and industrial camps. Of the 18 incorporated towns, two had dwindled in population (1920) to small villages of less than 100 inhabitants. The population (1920) of the other 16 averaged slightly more than 1,000, and, with the exception of Sitka (*q.v.*) the whites were in preponderance. Juneau, the capital and an important mining centre, was the largest town, with a population (1930) of 4,043. These towns are centres of business and social activities, as well as of Government agencies, covering considerable tributary areas, and scattered over a vast frontier region. They have, therefore, a dignity and importance in excess of that usually attached to towns of similar size in more populous regions. All have electric lights, telephones and other modern conveniences, and, with one or two exceptions, have modern water supply systems.

The natives of Alaska have been considered to fall under four ethnologic races: the Eskimo or Innuut—of these the Aleuts are an offshoot; the Haidas or Kaigani, found principally on Prince of Wales island and thereabouts; the Thlinkits, rather widely distributed in the Panhandle; and the Tinnehs or Athapascans, the stock race of the great interior country. Later studies by ethnologists have resulted in classifying all these except the Eskimos as remote offshoots of the North American Indian stock. The natives have adopted many customs of white civilization, their children attend Government schools, and on the Aleutians, in coastal Alaska, and in scattered regions in the interior acknowledge Christianity under the forms of the Orthodox Greek or other churches.

Government.—The District of Alaska was terminated and the Territory of Alaska created by an Act of Congress in 1912. The Organic Act under which Alaska became a Territory serves as its Constitution. The legislative authority was vested in a bicameral body, the upper chamber or senate, consisting of two senators from each of the four judicial divisions serving four years. Sixteen representatives form the lower chamber, or house of representatives, four elected for two years from each judicial division. This equal representation gives the less populated areas of the interior an unjust preponderance in the legislature and has not always worked for the best interest of the Territory as a whole. Under the Constitutional Act, Congress expressly retained the right of repealing all laws enacted by the Alaska legislature. Furthermore, the Territory was denied the right to enact laws relating to the excise, to game, fish, fur-bearing animals or to the existing Federal licence tax. Acts of the legislature are subject to veto by the governor as well as by Congress, but a measure may be passed over the governor's veto by a two-thirds vote of the members elected to each house. The executive and administrative authority is vested in a governor and a Territorial secretary, each appointed by the President for a term of four years; an attorney general elected by the voters of Alaska, for a term of four years; a Territorial treasurer, appointed by the governor with the consent of the Territorial senate, for four years; a commissioner of educa-

POPULATION OF ALASKA, TOTAL AND WHITE, AS ENUMERATED AT EACH CENSUS, 1880 TO 1920

tion appointed by the board of education for two years; and a commissioner of health appointed by the governor for two years. Each of the four judicial divisions has a judge, an attorney and a U.S. marshal, all appointed by the President for four years. The judges hold both the U.S. and Territorial courts. Each judicial division has a number of U.S. commissioners who are ex-officio justices of the peace, probate judges, coroner and recorders. Each town is permitted to have a municipal court. By an Act of Congress approved on June 6, 1900, towns were allowed to become incorporated municipalities. Up to 1927, 18 municipalities had been formed under this Act. Alaska is still hampered by divided control. The various departments and bureaux of the National Government and the Territorial Government often have overlapping duties and conflicting interests.

Finances.—The governmental expenses of Alaska are met in part by the Territorial Government and in part by the Federal Government. The chief sources of Territorial revenue are: a tax on the salmon fishing industry, a fur tax, professional and occupation licences, corporation fees, an insurance premium tax, 25% of the receipts of the National forests, an inheritance tax and a railway income tax. Of the disbursements about 46% were for education, the remainder being expended for roads, trails and air-ports, for charitable purposes and for official salaries and expenses. The total receipts for the biennium ending Dec. 31, 1926 were \$2,791,545. The disbursements for the same period were \$2,444,650.

There were 13 Territorial and four National banks operating in Alaska on Dec. 31, 1926. The combined resources of the 17 banks were \$13,018,634. The deposits subject to check were \$6,907,380 and time certificates and savings were \$4,315,073.

Education and Charities.—By an amendment passed to the Organic Act in 1917, Alaska became responsible for the education of its white population. The Alaska division of the national bureau of education is required to provide for the education of the natives, to train them in industry and to furnish them medical relief. The enrolment in the Territorial schools for the session 1925-26 was 4,352 pupils and 211 teachers. Of the total enrolment 581 were in high schools and 3,771 in elementary schools. The school term in incorporated towns ranged from nine to ten months and for rural districts from seven to nine months. During the fiscal year 1925 there were 3,912 natives enrolled in the schools supported by the Federal Government and 325 enrolled in three mission schools. The average length of term in the Government supported schools was 137 days. The only institution of higher education is the "land grant" Agricultural College and

School of Mines opened at Fairbanks in 1922. Its enrolment for the session 1925-26 was 94 men and 70 women.

The burden of charitable relief falls on both the Territorial and Federal Governments. The Territorial Government during the biennium 1924-26 expended \$308,400 or about 15% of the total revenue for the support of eleemosynary institutions, the care of the indigent, of children and the relief of the destitute. The insane of Alaska are cared for at Federal expense in a private institution.

Fisheries.—The product of the fisheries is about equal to the sum-total of all other Alaskan products. The total value of fish

marketed between 1867 and 1926 was about \$688,000,000. In 1925, according to the governor's report, the capital invested in Alaskan fisheries was \$67,077,495 and the value of the product was \$40,038,745. Salmon represents about four-fifths of the product. During the World War the salmon catch assumed such proportions that there was grave danger to the industry, but in 1924 Congress authorized the secretary of commerce to impose suitable

FISHING WITH SALMON PURSE SEINES IN SOUTH-EASTERN ALASKA

The purse seine, largely employed by salmon fishermen on river or sea shoals, is one of the modern methods that has aided the growth of Alaska's extensive fishing industry

restrictions. Since 1924 certain districts have been closed and others restricted in the interest of preserving the supply. The halibut fisheries were also being rapidly depleted, but in 1924 Congress ratified a treaty with Canada and Great Britain for the preservation of the halibut fishing of the northern Pacific; the value of the Alaskan catch in 1924 was \$1,619,443. Extensive cod-fishing banks from 22 to 90 fathoms deep are found in Bering sea and east of the Alaska peninsula. The number of cod on the Alaska banks is enormous, but as yet they have been but little

ALASKA'S OUTPUT OF CANNED SALMON FROM 1907 TO 1926

The output in 1926, 6,652,882 cases, was even higher than in 1918 and was nearly eight times as much as the output of the States of Washington, Oregon and California

exploited. Herring are also abundant and their catch has increased rapidly within recent years. Herring are used for bait, in the production of oil and fertilizer, and a limited quantity of the young fish are packed as "sardines." Whale fishing, once a very important industry, has practically ceased.

Agriculture and Live Stock.—In 1924 the best developed farming area was in the neighbourhood of Fairbanks, where hardy varieties of wheat were matured and a small flour-mill operated. There is an abundance of good grazing land in the interior, but the period of winter feeding is about eight months. The Matanuska valley has proved particularly adapted for breeding dairy cattle. The domesticated reindeer herds in 1924 were 350,000, valued at \$8,750,000. In 1927 the herd had grown to 675,000.

It is estimated that Alaska contains 120,000,000 ac. suitable for grazing of reindeer and capable of supporting 4,000,000 deer. This industry promises to be a very profitable one for the future of Alaska.

Furs.—Between 1867 and 1925 Alaska produced furs to the value of about \$107,000,000, of which about 55% represented sealskins taken on the Pribilof islands. Up to 1910 the Government leased the seal-catching privileges on these islands to private corporations, which killed 2,320,028 seals and paid the Government \$9,474,000 in royalties. The land killing of seal was re-

FUR SEALS UNDER GOVERNMENT PROTECTION ON PRIBILOF ISLANDS

Guarded by the United States Federal Government from unlicensed hunters since 1910, the fur seal has been increasing in number yearly, and is no longer in danger of extermination

stricted, but pelagic sealing, which was becoming very destructive, could not be controlled by the American Government; a treaty was therefore signed in 1911 between the United States, Great Britain, Russia and Japan, abolishing it and providing that the United States was to pay to both Great Britain and Japan 15% of the value of the catch made on the islands. Since 1910 killing has been prohibited on the Pribilof islands, except by U. S. agents. Thanks to these provisions the seal herd increased from 215,000 in 1912 to 723,050 in 1925. In that year 19,860 sealskins were taken from the herd. The annual production of fur, other than seal, was valued at approximately \$2,000,000 in 1925. Most

THE ORIGINAL STOCK OF 1280 REINDEER BROUGHT INTO ALASKA FROM SIBERIA IN 1892-1902 INCREASED TO ABOUT 500,000 HEAD IN 1926, OF WHICH 235,000 WERE OWNED BY THE NATIVES

of this was due to the rapid increase of fox-farming, about 400 fur farms being in operation. Two companies were engaged in sheep-grazing in the Aleutian islands.

Minerals.—As early as 1861 gold discoveries were made on the Stikine river; repeated discoveries, culminating in the Cassiar district "boom," were made in British Columbia from 1857 to 1874; colourings along the Yukon were reported in 1866-67 and systematic prospecting of the upper river began about 1873. Juneau was founded in 1880; the same year the opposition of the

Indians, which prevented the crossing of the mountain passes to the interior, was withdrawn, and after 1880 repeated and scattered discoveries were made on the Lewes, Pelly, Stewart and other streams of the Upper Yukon country in Canada. As early as 1883-85 there was a considerable mining excitement due to these discoveries, and a much greater one in 1887 after the discovery of coarse gold on Forty Mile Creek in American territory; but these were as nothing to the picturesque and feverish rush that

BY COURTESY OF THE CANADIAN PACIFIC RAILWAY
LOVETT'S GULCH ON BONANZA CREEK IN THE KLONDIKE, YUKON, A
SPOT FAMOUS IN THE HISTORY OF THE GOLD RUSH OF 1898

followed the location of the first Klondike claim in Canadian territory in Aug. 1896.

The total value of the mineral output of the Territory from 1880 through 1927, was \$586,000,000. Of this \$365,700,000 was for gold, \$196,172,878 for copper and \$11,183,588 for silver. Alaska also produces coal, lead, tin, platinum, palladium, antimony, tungsten, natural gas, petroleum, marble, gypsum, graphite, barite and sulphur. Copper mining, begun in 1901, was in 1927 the chief mineral industry. For a decade copper has annually exceeded in value the output of all other minerals. Copper ores are widely distributed, but most of the deposits are as yet inaccessible. The output has been largely that of the Kennecott mines in the Chitina district. Coal, both bituminous and anthracite, occurs in the Bering River, and the Matanuska fields, which lie within reach of the Government railway. The Territory, also, contains an abundant supply of sub-bituminous and lignite coals, which are very widely distributed. The production up to 1925 was about 670,000 tons. The transportation problem for districts distant from the railway is still a drawback to the industry.

Important oil seepages have been found at five places on the Pacific seaboard, and at two places in the Naval Petroleum Reserve No. 4 on the North Arctic coast. The withdrawal of all oil lands from entry in 1911 stopped development until 1919, when an oil-leasing law was passed and operations begun in several localities; up to 1925 the production of petroleum had been confined to the Katalla field. About 12,700,000 oz. of silver and 7,000 tons of lead have been produced. Almost all the tin output of North America comes from Alaska, chiefly from the New district in the Seward Peninsula; over 1,000 tons had been mined between 1900 (when operations began) and 1925. The mining of platinum and related minerals began in 1916, and about 1,600 oz. had been produced by 1925. Quicksilver mining has been carried on in a small way for many years. In south-eastern Alaska extensive deposits of high-grade marble have been quarried on a large scale.

Timber Production.—The commercial timber of Alaska is contained in the two great national forests, the Tongass in south-eastern Alaska and the Chugach on Prince William Sound. They had, in 1925, a total area of 21,334,274 ac., and were estimated to contain 84,760,000,000 board ft., of saw timber, of which 74% was western hemlock and 20% Sitka spruce. The remainder was largely western red cedar and Alaskan cedar. Saw-mills are developing rapidly, the lumber cut of the national forests in 1925 being 57,500,000 board ft., or an increase of 500,000 board ft. over the 1924 production. The total cut since 1909 was estimated

at 639,500,000 board ft., but this production is still far under the natural increase. In 1925 a pulp-wood industry was being developed under the encouragement of the forest service.

Communication and Transportation.—Transportation facilities have greatly improved since 1900. All the important centres of population have regular mails, cable, telegraph or wireless communication, with the United States, and steamer connection the year around with all coast towns except Nome. Aeroplane service also is being rapidly developed. In 1900 there were only 22 m. of railway in Alaska but by 1910 there were 390 m. in operation. This mileage included 20 m. of the White Pass railway (narrow gauge) which ran inland from Skagway across the international boundary to White Horse in the Canadian Yukon (110 m.). While primarily serving Canadian territory, this line gives access, during the open season of navigation, to the settlements on the lower Yukon. The Copper river and North-western railway, extending from Cordova on the coast to the Chitina copper belt (196 m.), was completed in 1910. In 1912 Congress authorized a special commission to report upon the Alaskan railway situation. This commission recommended the construction of two lines: one from Cordova to Fairbanks, the other from Seward to the navigable waters of the Kuskokwim. The estimated cost, \$35,000,000 was appropriated by Congress in 1914, but in the following year the Administration announced the selection of a railway route from Seward to Fairbanks, a far more expensive undertaking. Construction on the Alaska Railroad was begun in 1915 and finished in June 1923, at a total initial cost of \$56,000,000. Appropriations since that date bring the total cost up to near \$70,000,000. This system, with its branch lines to Matanuska and Chickaloon coal-fields, has a total length of 540 miles. The governor of Alaska, in his annual report for 1926, stated that excellent progress had been made in the construction and maintenance of roads and trails by the Alaska road commission and the bureau of public roads working in co-operation with the Territory. In 1925 the legislature authorized the territorial road board to divert from the 1925 road appropriation sums necessary for the construction of aviation fields. By July 1, 1926, 23 such fields had been constructed and there were two aviation companies operating from Fairbanks.

In 1924 minerals, furs, fish, etc., were exported to the value of \$61,015,062, and the value of imports was \$32,580,057. During that year 2,802 vessels entered Alaskan ports and 2,675 vessels were cleared. Coastal Alaska was served by three regular passenger and freight steamship lines which during 1924 operated 12 steamers. A boat service was furnished on the Tanana and Yukon rivers by the Alaska Railroad.

Exploration and Early History.—In the early explorations of the north-west coast of America, Spain was first in the field, but there is little evidence to prove that any Spanish navigator sailed as far north as Alaska. Later, and during the period of active Russian exploration, a number of expeditions were sent north from Mexico and at one time Spain claimed the sole right to navigate the waters of the northern Pacific and issued a prohibition against other nations trading in those waters. Many Spanish names of places along the coast remain to-day to attest the extent of these explorations. Spain does not appear to have pressed her claims, however, and gradually ceased her efforts in this direction. This may have been due to disputes on her hands in other parts of the world or to the wide extent at that time of the Spanish claims in the western hemisphere or possibly, in part, to the fact that the climatic conditions of this northern region did not appeal strongly to a people whose life and activities had been spent in warmer climes. To the Russian, on the other hand, these regions were as home. During the latter half of the 17th century, the Russians had been pushing their explorations across Siberia and along the eastern and northern shores of Asia. In 1728 Vitus Bering passed through the strait named after him and Girondeff sighted the American coast in 1731. Bering's second expedition, in company with Chirikov, sailed from the Siberian coast in 1741. The mainland of America was located and numerous islands visited. This expedition is commonly accepted as fixing the date of the discovery of Alaska. Bering's ship was

wrecked in early November on what is now called Bering Island. The crew made such provision as was possible against the cold of the approaching winter, but the privations and hardships were very great. "It was under such circumstances that Vitus Bering died—on this cold, forbidding isle, under the sky of an Arctic winter, December 8, 1741." During the 30 or 35 years following, the Russians were active in exploring the coast and islands and in establishing a trade with the natives.

About the time the American colonies were making their struggle for separation from the mother country, England was beginning her part of the exploration of this north-west coast. Three names stand high in the record of these explorations: Cook, Vancouver and Mackenzie. Cook's expedition sailed from England in July, 1776. In the personnel of his expedition were men from the American colonies, and Vancouver, then a midshipman, was of the party. The work begun by Cook was continued by Vancouver during the years 1791 to 1794. Dall expressed the view generally held concerning Vancouver's work in the statement that: "The explorations which he carried out have not been excelled by any other navigator and were faithfully and thoroughly performed." The Hudson's Bay Company was meanwhile advancing its trade and extending its influence westward from the interior of Canada. In 1793 Alexander Mackenzie crossed the continent by land to the Gulf of Georgia, returning by the same route. This expedition, although little known, may well be compared with that of Lewis and Clark, in respect both of the difficulties encountered and of its value to his company and Government.

The excesses committed by private traders and companies, who robbed, massacred and hideously abused the native Indians, caused the Russian Government in 1799 to confine the trade and regulation of its American possessions to a semi-official corporation called the Russian-American Company for a term of 20 years, afterwards twice renewed for similar periods. Alexander Baranof, chief resident director of the American companies (1790-1819), and one of the administrators of the new company, became famous through the success he achieved as governor. He founded Sitka (*q.v.*) in 1804 after the massacre by the natives of the inhabitants of an earlier settlement (1799) at an adjacent point. The headquarters of the company were at Kodiak until 1805, and thereafter at Sitka. In 1821 Russia attempted by *ukase* to exclude navigators from Bering Sea and the Pacific coast of her possessions. This led to immediate protest from the United States and Great Britain. The outcome was a treaty with the United States in 1824 and one with Great Britain in 1825, by which the excessive demands of Russia were relinquished and the boundaries of the Russian possessions were established. In the convention with Great Britain, it was agreed that Russia should have the narrow strip of coast north of 54° 40' and the peninsula and islands westward of the 141st meridian.

The last charter of the Russian-American Company expired on Dec. 31, 1861, and Prince Maksutov, an imperial governor, was appointed to administer the affairs of the territory. Authority was granted to an American company in 1864 to make explorations for a proposed Russo-American company's telegraph line overland from the Amur river in Siberia to Bering Strait, and through Alaska to British Columbia. Work was begun on this scheme in 1865 and continued for nearly three years, when the success of the Atlantic cable rendered the construction of the line unnecessary and it was given up, but not until important explorations had been made. Much of this information was made public in 1870 by W. H. Dall in his book *Alaska and its Resources*.

The first official overtures by the United States for the purchase of Russian America were made by Senator Gwin of California

(1859) during the presidency of James Buchanan. This movement, however, was checked temporarily by the Civil War, which soon followed. The fishing interests of north-western United States were next to manifest an interest in the territory to the northward. In 1866 a memorial was adopted by the legislature of the Washington Territory, "in reference to the cod and other fisheries," and delivered to President Johnson. By a treaty signed on March 30, 1867, the purchase was consummated for the sum of \$7,200,000, and on Oct. 18, 1867, the formal transfer of the territory was made at Sitka.

Later History.—Since its acquisition by the United States, the history of Alaska has been mainly that of the evolution of its administrative system and the varying fortunes of its gold-fields, fisheries and sealing industries. Alaska was an unorganized Territory from 1867 until May 1884. From 1867-77 the Government was in the hands of the Department of War, although the customs were from the beginning collected by the Treasury, with which the control rested from 1877 until the passage of the so-called Organic Act of May 17, 1884. This Act extended over Alaska the laws of the State of Oregon so far as they should be applicable, created a judicial district and a land district, put in force the mining laws of the United States, and in general gave the administrative system the organization it retained up to the reforms of 1899 and 1900. The history of government and political agitation then centred in the demand for general land legislation and for an adequate civil and criminal law, in protest against the enforcement of a liquor prohibition Act, and in agitation for an efficiently centralized administration. After partial and inadequate legislation from 1891 to 1898, the regular system of land surveys was made applicable to Alaska in 1899, and a generous homestead law was provided in 1903. The liberal land policy was completely reversed as a result of the conservation movement inaugurated under President Roosevelt. The original aim of the movement was to prevent waste of natural resources, but this gradually veered to a protest against corporate control of lands and resources. An important result of the conservation movement was the increase of reservations in Alaska, some 40,000sq.m. being set aside for various purposes, exclusive of mineral and forest withdrawals. For many years, however, the conservation issue remained unsettled and industry languished; with an abundant supply of fuel close at hand, Alaska was forced to import petroleum and coal at great cost; her pulp wood was rotting in the forests; her water-power was undeveloped. Only gold and copper mining and salmon fishing increased. Finally during the Wilson Administration, a leasing policy for coal and oil lands and water-power was established by law. It was also during this period that the Government began the Alaska railway which was completed in 1923. The shortage of print paper after the war had a liberalizing influence on the regulations regarding the sale of timber from the national forests and the contracts governing pulp mills.

The struggle of Alaska to attain representation at Washington resulted in 1906 in the authorization of an elected delegate to Congress. At each biennial election which followed, home rule was the only important issue, until in 1912 an Act was passed granting a limited Territorial government. The first Territorial legislature was convened at Juneau on March 3, 1913, and the first law passed gave the franchise to women. Since that date the most important legislation has related to mining, hours of labour, workmen's compensation, banking and education.

The agitation over prohibition dated from 1868; the Act of that year organizing a customs district forbade the importation and sale of fire-arms, ammunition and distilled spirits; the Organic Act of 1884 extended this prohibition to all intoxicating liquors. Smuggling flourished; juries steadily refused to convict offenders and treasury officials regularly collected revenue from saloons existing in defiance of law. In 1900 the sale of liquors was authorized under what was known as the high license law. In 1916 the legislature authorized a plebiscite on the prohibition of the sale, transportation and manufacture of all alcoholic beverages. The vote was in the affirmative by 7,958 to 4,431; as the legislature had no power to change the excise law, a petition

CARVED WOODEN SPOON
USED BY THE INDIANS OF ALASKA

was submitted to Congress which passed a dry law for Alaska in 1917.

Two events of international interest growing out of Alaska were the Fur Seal Arbitration of 1893 (see *BERING SEA ARBITRATION*), and the Alaskan-Canadian boundary dispute, previously mentioned, settled by an international tribunal of British and American jurists in London in 1903. The boundary dispute involved the interpretation of the words in the treaties of 1825 and 1867 defining the boundary of the Russian (later American) possessions, and also the determining ownership of the Portland canal and the question whether the coastal girdle should cross or pass around the heads of the fiords of the coast. The award of the tribunal made in Oct. 1903 was arrived at by the favour-

able vote of the three commissioners of the United States and of Lord Alverstone, whose action was bitterly resented by the two Canadian commissioners; it sustained in the main the claims of the United States.

Very little was known about the interior of Alaska previous to 1896, when the gold discoveries in the Klondike stimulated public interest regarding it. Since 1895, however, the exploration of the United States geological survey and the Department of War, as well as those of individuals, have established the main features of its physiography and a rather accurate knowledge of its resources. The highest peak of Mt. McKinley (20,300ft.) was conquered in 1912 by Hudson Stuck and Harry P. Karstens. Alaska was chosen as the objective of the Amundsen polar expedition on the journey from Spitsbergen over the North Pole in 1926. The Wilkins expedition selected Point Barrow as a base for its aeroplane explorations during 1926, 1927 and 1928; and it was from this point that Wilkins and Eielson made their successful aeroplane flight across the Arctic region to Spitsbergen in April 1928. These exploits demonstrated that transportation over air routes, even during the winter months, is possible.

S. Blount, *North of Fifty-three; an Alaskan Journey* (1924); and E. Roseman, *Black Sunlight; a Log of the Arctic* (1926).

(G. McL. Wo.; W. P. R.)

ALASTOR, in early Greek mythology, the spirit of revenge, that prompts the members of a family to commit fresh crimes to obtain satisfaction. Further acts of vengeance transmit the curse from generation to generation. The word is also used for a man's evil genius which drives him to sin; a man so driven is sometimes called *Alastor*. The epithet is applied to the Furies (Erinyes) as the deities of revenge, and to Zeus when he is invoked as the "Avenger."

ALA-TAU (variegated mountains) is the name given to the following ranges in Asiatic Russia: (1) Terskei, (2) Kunghei and (3) Trans-ili, all three linking the Tian Shan and the Alexander range. (1) Lies south, and (2) and (3) north of and parallel to Lake Issyk-Kul. Average height 6,000-7,000ft. (Mt. Talgar 15,000ft.). Snow-line 11,000-11,700ft. (4) Also called Talastau, west by south from the Alexander range. (5) Dzungarian Alatau, a range bordering the Dzungarian gate, north of the Tian-shan, average height 6,250ft., max. 11,000ft. (6) Kuznetsk-Alatau, between the upper Ob and the upper Yenisei, west of the Abakan mountains. Average height 6,000-7,000ft. For No. 6 see KUZNETSK.

ALATYR, a town in Chuvash, A.S.S.R. Pop. (1926) 22,374. It is situated in latitude 54° 53' N. and longitude 46° 30' E., at the junction of the Alaty and Sura rivers. It has a grain elevator and an extensive grain trade, also flour mills and starch factories.

ALAUNA, ALAUNUS, the Celtic names of two rivers, etc., in Roman Britain. Hence the modern Allan Water, river Alyn, etc.

ALAVA, DON MIGUEL RICARDO DE (1770-1843), Spanish general and statesman, was a member of the assembly at Bayonne in 1808 which accepted Joseph Bonaparte as king of Spain, but shortly afterwards joined the national independent party which was fighting in alliance with the English.

He was Spanish commissary at Wellington's headquarters, and before the end of the campaign had risen to the rank of brigadier-general. In 1815 he was ambassador at The Hague, and was present at the battle of Waterloo. He had served at Trafalgar on the flagship of his uncle, Admiral Alava, and was said to be the only man to have been present at both Trafalgar and Waterloo. He was a deputy to the Cortes in 1820, and in 1822 fought in the militia to support the authority of the Cortes against the rebels.

Alava took part in the negotiations for the restoration of Ferdinand, but was soon driven into exile. Returning to Spain after Ferdinand's death, he supported Maria Christina against Don Carlos, and was again sent abroad as ambassador, first to London (1834) and then to Paris (1835). He refused to take the oath to the Constitution of 1837, and died in exile at Barèges, France, in 1843.

Alava's name is repeatedly mentioned in the Duke of Wellington's correspondence.

ÁLAVA, one of the Basque Provinces of northern Spain. Pop. (1920) 98,668; area, 1,176sq.m.; density per sq.m., 83.9. The township of Treviño (190sq.m.) in S. Álava belongs to the province of Burgos. Álava (Basque *araiar*, country set among mountains) is in the west and north-west of a district of mountain and valley, drained by the rivers Boyas and Nervión. The centre of the province is the large, fertile plain of Vitoria which continues to the west the structural trough separating the Sierra de Aralar, on the north, from the Sierra de Andia, on the south. The

Montes de Vitoria separate this plain from the lower plain of Treviño, a dried-up lake basin running east from the Ebro at Miranda and bounded on the south by the Sierras de Toloño and de Cantabria. South of these sierras lies the lowest of the three plains of the province, the Alavese Rioja, with a water-frontage on the Ebro between Haro and Logroño.

Formerly a lordship, governed by an elective *señor*, Álava was incorporated in Castile in 1332 at the request of the electoral corporation of clergy and nobility, who celebrated with Alfonso XI. of Castile the Convention of Arriaga defining administrative relations between the lordship and Castile. The modern province is in many respects transitional between the Basque country and Castile. Castilian is the ordinary language except in the north.

Rainfall is fairly regular, except in the Alavese Rioja. About 27% of the soil of the province is cultivated, producing wheat (64% of the cereal area, 1924), barley, oats and sugar-beet; maize is grown on the Bizcayan and Guipuzcoan border only. Agricultural methods are, for Spain, progressive, owing to the educative effect of sugar-beet cultivation, and artificial fertilizers and modern ploughs are in general use. The wine of the province is renowned, especially that of the Alavese Rioja; attacks of phylloxera have diminished the area devoted to viticulture, but more than 11,000 acres (1924) have been replanted with American stocks. Forests of chestnut, oak and beech, controlled by the provincial authority, and rough pastures occupy 46% of the province. Livestock in 1925 included 32,042 horned cattle, 90,075 sheep, 32,891 goats and 31,136 swine. Goats and sheep are exported to Barcelona, cattle to the market of Bilbao. Irrigation is not in use except for horticulture, but the streams are harnessed to supply electric power and light. Salt and asphalt are worked; lignite, important in the war-time shortage of coal, is no longer profitable. Steel, pig-iron and puddled iron are produced (total value, 1923, 2,867,289 pesetas); and there are manufactures of beds, furniture, railway carriages, matches, paper, sweets and woollen and cotton goods. Bread-stuffs, colonial products and machinery are largely imported. In Álava the rate of illiteracy is only 16.24%; there are secondary schools at Vitoria, the capital (pop. 1920, 34,785), which is the only town of more than 3,500 inhabitants, and good normal schools for teachers of both sexes. (See BASQUES and BASQUE PROVINCES.)

BIBLIOGRAPHY.—M. Risco, in vol. 33 of *Hispania Sagrada* by H. Florez and others (1754–1879); A. A. Salazar, *Catálogo de las obras referentes a las provincias de Álava y Navarra* (1887, bibl.).

ALB, a liturgical vestment of the Catholic Church. It is a sack-like tunic of white linen (Lat. *alba*, white) with narrow sleeves, and a hole for the head to pass through, and when secured round the waist by the girdle (*cingulum*) just clears the ground. Albs were originally plain, but about the 10th century the custom arose of ornamenting the borders and the cuffs of the sleeves with strips of embroidery, and this became common in the 12th century. These at first encircled the whole border; but soon it became customary to substitute for them square patches of embroidery or precious fabrics. These "parures," "apparels" or "orphreys" (Lat. *paruræ*, *grammata*, *aurifrisia*, etc.) were usually four in number, one being sewn on the back and another on the front of the vestment just above the lower hem, and one on each cuff. A fifth was occasionally added just below the neck opening. In the 16th century the parures began to go out of use, and broad bands of lace soon afterwards replaced them, as in a magnificent specimen preserved at South Kensington. Appareled albs are now only in regular use at Milan (Ambrosian Rite), and, partially in certain churches in Spain; but attempts have been made, especially in England, to revive their use.

The alb is worn by bishops, priests, deacons and subdeacons under the other eucharistic vestments at mass and at functions connected with it. It is sometimes also worn by clerics in minor orders, whose proper vestment is, however, the surplice—itself a modification of the alb. (See SURPLICE.) The alb is supposed to symbolize purity, and the priest, when putting it on, prays: "Make me white, O Lord," etc. In the middle ages the parures were taken to symbolize the wounds of Christ; and at Toledo the singers of the Passion on Good Friday still wear appareled albs.

In England at the Reformation the alb went out of use with the other "Mass vestments," but was reintroduced in the ritual revival of the 19th century. It is now worn in many churches not only by the clergy but by acolytes and servers at the Communion. Where the ritual is a revival of pre-Reformation uses, these albs are frequently appareled. (For the question of its legality see VESTMENTS.)

Both the alb and its name are derived from the *tunica alba*, the white tunic, which formed part of the ordinary dress of Roman citizens under the empire. The date of its definite adoption as a liturgical vestment is uncertain; at Rome—where until the 13th century it was known as the *linea* or *camisia* (cf. the modern Italian *camice* for alb)—it seems to have been thus used as early as the 5th century. But as late as the 9th and 10th centuries the *alba* is still an everyday as well as a liturgical garment, and we find bishops and synods forbidding priests to sing mass in the *alba* worn by them in ordinary life. (See Braun, p. 62.) In mediaeval inventories are sometimes found *albe*, described as red, blue or black; it is clear, however, from the descriptions of these vestments that in some cases they were actually tunics, the confusion of terms arising from the similarity of shape (see DALMATIC); in other cases the colour applied to the parures, not to the albs as a whole. Silk albs appear in the inventories, but only very exceptionally.

The equivalent of the alb in the Eastern Churches is the sticharion (σχιχάριον) of the Orthodox Church (Armenian, *shaphik*; Syrian, *Kutina*, Coptic, *stoicharion* or *tuniah*). It is worn girdled by bishops and priests in all rites, by subdeacons in the Greek and Coptic rites; ungirdled, by deacons and lectors in all the rites. It is usually white for bishops and priests; for the other orders all colours, except black, may be used. Its material may be linen, wool, cotton or silk; but silk only is the rule for deacons. In the Armenian and Coptic rites the vestment is often elaborately embroidered; in the other rites the only ornament is a cross high at the back, save for bishops of the Orthodox Church, whose sticharia have two vertical red stripes (πόταμοι, "rivers"). As in the West, the vestment is specially associated with the Eucharist. The whole subject is exhaustively treated by Father Joseph Braun in *Die liturgische Gewandung* (Freiburg im Breisgau, 1907). (See also bibliography to the article VESTMENTS.)

ALBA, town and episcopal see, province of Cuneo, Piedmont, Italy, 42m. S.E. of Turin by rail. Pop. (1921) 8,904 (town), 14,213 (commune). The fine cathedral, with Gothic façade, was rebuilt in 1486. *Alba Pompeia* was probably founded by Pompeius Strabo (consul 89 B.C.) when he constructed the road from Aquae Statiellae (Acqui) to Augusta Taurinorum (Turin). The emperor Pertinax was born here. It became an episcopal see dependent on Milan in the 4th century. It is the centre of a wine-growing district.

ALBACETE, inland province, south-east Spain, formed in 1833 out of the northern half of Murcia. Pop. (1920), 291,833; area, 5,471 sq.m.; density per sq.m. 50.8. A somewhat featureless province; except for the Sierra de Alcaraz in the west, Albacete continues south-east of the monotonous arid steppe land of La Mancha. Lying in the south-eastern corner of the central plateau, where the border of the plateau is less clearly marked by mountains than elsewhere, the province is crossed by the main routes from Madrid both to the Valencian plain and to the south-east. The drainage is almost entirely to the Mediterranean by the rivers Júcar and Segura, but the rainfall is low and the province contributes little to the volume of these rivers except from the western sierras. In these sierras the snow lies for several months; elsewhere the climate is mild and healthy. About 55% of the province is cultivated land, of which cereals—wheat, barley, oats, rye and maize in order of importance occupy nearly half. Albacete is a stock-raising province, but the acreage devoted to wheat shows a steady rise, with much breaking-up of natural pastures and a corresponding decline in live stock. Of these, sheep, belonging to the large Manchigan breed with its all-round production, are now the most important (1924, 369,627); sheep and wool are exported to Barcelona and Valencia, and cheeses to all parts of Spain. The vine has suffered much from repeated attacks of

phylloxera, and replacement with local stocks has been unsuccessful; olives are cultivated; the peaches of the Cabriel and Júcar valleys supply canning factories in Valencia. Saffron and esparto (wild) are exported, and employ much labour. There are important pine forests. Manufactures are almost confined to the spinning of hemp and the making of coarse cloth, porcelain, earthenware and cutlery. Brandy is distilled, and there is some trade in wood. Albacete, the capital (pop. 1920, 31,960), and the other important towns, Almansa and Hellin, are described separately. The railroad from Madrid to Albacete passes south-west to Chinchilla, where it bifurcates, one line going to Murcia and the other to Alicante. A large part of the province is accessible only by road. In respect of elementary education, Albacete is one of the seven most backward provinces, with 65.89% of the population returned as illiterate.

ALBACETE, capital of a Spanish province is in a fertile plain where the Balazote unites with the canal of María Cristina, which flows into the Júcar, 16m. to the north. Pop. (1920) 31,960. Albacete comprises the picturesque old upper and lower town mostly erected after the city became a provincial capital in 1833. Chiefly a market-town for saffron and other agricultural produce and for live-stock, it also manufactures matches. Albacete formerly had an extensive trade in cutlery, from which it was named the Sheffield of Spain, and its daggers are still held in high repute by Spaniards.

ALBACORE, a large West Indian fish allied to the tunny (q.v.). The name is also applied to an allied species in the Pacific.

ALBA FUCENS (mod. *Albe*), an ancient Italian town on a lofty site (3,347ft.) at the foot of Monte Velino, 4m. N. of Avezzano. Originally a town of the Aequi, on the frontier of the Marsi, it was occupied by a Roman colony and its fortifications (c. 300 B.C.) persist. It lay on a hill just to the north of the Via Valeria, which was probably prolonged beyond Tibur at this very period. Later it became a regular place of detention for important State prisoners, such as Syphax of Numidia, Perseus of Macedonia, Bituitus, king of the Arverni. Its strong position made it important in the civil wars. The external walls, a circuit of about 2m., are of polygonal masonry; carefully jointed, with faces smoothed. The gates as a rule come at the end of a long, straight stretch of wall, and are placed so as to expose the right side of an attacking force. On the north there is, for a length of about 150yds., a triple line of defences of later date, possibly added by the Roman colonists, inasmuch as both the city wall proper and the double wall thrown out in front of it are partly constructed of concrete and faced with finer polygonal masonry.

BIBLIOGRAPHY.—C. Promis, *L'Antichità di Alba Fucense* (1836); R. Gardner in *Papers of the British School at Rome* X. (1927).

ALBA IULIA, a town of Transylvania, Rumania (Ger. *Karlsburg*, Hung. *Gyula-Fehérvár*), situated on the Mureş, 73m. S. of Cluj by rail. Pop. (1924) 13,400. Alba Iulia, which consists of an upper town or citadel, and a lower town, is the seat of a Roman Catholic bishop and has a fine cathedral in 11th century Romanesque, rebuilt in 1443 by John Hunyady in Gothic style. It contains among other tombs that of John Hunyady. Near the cathedral are the episcopal palace and the Batthyaneum, founded by Bishop Count Batthyány in 1794, containing a valuable library with many incunabula and old manuscripts, amongst which is one of the *Nibelungenlied*, an observatory, a collection of antiquities and of minerals. The citadel was built in 1716–35 by the emperor Charles VI. Alba Iulia occupies the site of the Roman colony *Apulum*, and many Roman relics are in the museum. The bishopric was founded in the 11th century by King Ladislaus I. (1078–95). In the 16th century the town became the residence of the independent Transylvanian princes. From this period dates the castle and also the buildings of the university, founded by Gabriel Bethlen and now used as barracks. Alba Iulia with Cluj was the traditional centre of the Rumanian national movement in Transylvania; it was here that Michael the Brave proclaimed himself prince of Transylvania, Wallachia and Moldavia; here the union of Transylvania with Rumania was proclaimed in 1918 and King Ferdinand of Rumania was crowned in 1922. A peasant

congress assembled at Alba Iulia in the spring of 1928, to protest against the Brătianu policies, but was without result.

AL-BALADHURI (Ahmad ibn Yahya) (d. 892), native of Baghdad; one of the earliest Arab historians and the best authority for the period of the formation of the Arab empire. His chief work, *Futūḥ al-Buldān*, gives an account of the conquest of Arabia, Syria, Mesopotamia, Armenia, Egypt and north Africa, Spain, the Mediterranean islands, Nubia, Persia, and Media. It has been translated into English by P. K. Hitti under the title *The Origins of the Islamic State* in the *Studies in History, Economics and Public Law* series of Columbia university (1916). A second work, *Ansāb al-Ashraf* (Lineage of Nobles), was edited by Flügel (Leipzig 1835).

ALBA LONGA, an ancient city in Latium, on the western edge of the Albanus Lacus, about 12m. S.E. of Rome. Ascanius is the traditional founder and said to be the oldest of Latin cities, destroyed by its daughter city of Rome, under Tullus Hostilius, to which passed the hegemony of the Latin league. It has by many topographers been placed between the Albanus Mons and the Albanus Lacus, according to the indications of Dionysius, at the monastery of Palazzolo; but the position is quite unsuitable and does not answer to Livy's description, *ab situ porrectae in dorso urbis Alba longa appellata* (it was called Alba¹ Longa because it stretched along a narrow ridge); and its site is probably on the west side of the lake, where the modern Castel Gandolfo stands. Confirmation of this may be found in Cicero's description (*Pro Milone*, 85) of the destruction of the shrines and sacred groves of Alba by the construction of Clodius's villa, in the local application of the adjective *Albanus*, and in the position of Castel Gandolfo itself. Only the necropolis remains are preserved; the earliest tombs are Villanovan (about 1100 B.C.). Later ones are 7th and 6th centuries B.C. None was found, as has been alleged, buried by a subsequent eruption of the Alban volcano. The name *Albanum*, from about 150 B.C. till the time of Constantine, meant a villa in the Alban territory. The emperors formed a single estate out of a considerable part of this district, including apparently the whole of the lake, and Domitian was especially fond of it. The imperial villa occupied the site of the present Villa Barberini at Castel Gandolfo, and considerable remains still exist. To the south a camp, with baths, an amphitheatre, a large water reservoir, etc., was constructed for the Second Parthian legion, as his body-guard, by Septimius Severus. The camp was given up in the time of Constantine, when the *Civitas Albanensis* arose.

The lapis Albanus is a green grey volcanic stone with black and white grains in it (hence the modern name, peperino), much used for building material in Rome and its neighbourhood.

For detailed accounts see T. Ashby, *Jour. Phil.* xxvii. 37 (1901); G. Lugli, *Bull. Comm.* (1917–20) and *Ausonia*, ix. 211; x. 210. MacIver, *Villanovans and Early Etruscans* (Oxford, 1924); *Italy in the Iron Age* (Oxford, 1927).

ALBAN, SAINT, the first martyr of Britain, is said to have been born at Verulamium (St. Albans, Hertfordshire) and to have served for seven years in Rome in the army. On his return to Britain he is said by Gildas to have been put to death as a Christian during the persecution of Diocletian (c. 286–303), according to Bede, at St. Albans. As there is no certainty that the persecution of Diocletian extended to Britain it is possible that his martyrdom should be ascribed to that under Decius (250–251) or that of Valerian (259–260). A church was built on the place of his martyrdom, c. 793. A monastery was subsequently added, and around it the present town of St. Albans gradually grew up. Pope Adrian IV., who was born in the neighbourhood, conferred on the abbot of St. Alban's precedence over his fellow abbots, a right hitherto attached to the abbey of Glastonbury. St. Alban is commemorated in Catholic martyrology on June 22 and in the Church of England on June 17.

See U. Chevalier, *Répertoire des sources historiques* (1905), i. 95; D. Hardy, *Descriptive Catalogue* (1862), I. i. 3–34, ii. 688.

ALBANI, DAME EMMA, née LAJEUNESSE (1852–1930), celebrated Canadian singer, who was born in Chambly, Quebec,

¹Whether Alba means "white" is very doubtful: it is more probably derived from the root Alp.

on Nov. 1, 1852. She made her first public appearance in Montreal, at the age of seven, and after studying at Milan with Lamperti (on whose advice she adopted for stage purposes the name of Albani, after that of an extinct Italian family) she made her début at Messina in Bellini's *La Sonnambula*, achieving an immediate success, which was repeated when two years later, on April 2, 1872, she made her first appearance at Covent Garden in the same opera. Thenceforward for a long period she enjoyed the widest fame and popularity, being not less esteemed as a woman than admired for her art. She married in 1878 Ernest Gye, who died in 1925, and in the same year she was accorded the D.B.E. She died in London on April 3, 1930.

See her *Forty Years of Song* (1911).

ALBANI or ALBANO, FRANCESCO (1578-1660), Italian painter, was born at Bologna. His first master was Denis Calvert, with whom Guido Reni was at the same time a pupil. He was soon left by Calvert entirely to the care of Guido whom he followed to the school of the Caracci. Albani opened an academy in Rome, where he resided for many years. Here he painted, after the designs of Annibal Caracci, the whole of the frescoes in the chapel of San Diego in the church of San Giacomo degli Spagnuoli. His best frescoes are those on mythological subjects, of which there is a large number in the Verospi, now Torlonia Palace. A number of his works are at Bologna, and others at Florence, the Louvre, Dresden and Leningrad.

ALBANIA, an independent kingdom lying on the west coast of the Balkan peninsula, between Greece and Yugoslavia, with an area of 27,538 square kilometres and a population of 1,003,068, formed out of the earlier Turkish provinces of Scutari and Yanina, with parts of the vilayets of Kosovo and Monastir. Though the Albanian kingdom may be said to date only from the year 1920, when a national assembly was convoked, and the national boundaries were not demarcated till 1925, the state displays a certain individuality, distinguishing it from its two larger neighbours.

The Albanian lands lie athwart the mountain chain of the Dinaric Alps, but, as contrasted with Dalmatia to the north and Greece to the south, these here stand back from the sea, from which they are separated by a marshy and malarious lowland, crossed by several important rivers. The actual coast is generally low, and the shore waters are rendered turbid by the silt carried down by the rivers, thus contrasting markedly with the clear blue tint off the limestone country further north. Equally marked is the general absence of the coastal settlements so characteristic of most parts of the Mediterranean. Southwards, in the region near the port of Valona, the coastal lowland disappears, and limestone hills again approach the water's edge. In this, the region anciently called Epirus, the Greek mode of life becomes visible, though Greek penetration was always limited. The Albanians have been in the past and still are mainly mountain folk, occupying the hilly interior rather than the coastal lowland. The continuity of the mountain belt gives them a certain cultural unity, while at the same time the fact that it is broken up into a series of small natural regions, more or less isolated from each other, has made the growth of a national spirit a slow process. The country has thus three essential features which go far to explain the history and characteristics of its people: because of the littoral plains it marks a definite break in the otherwise mountainous west coast of the peninsula; its elevated hinterland forms a natural refuge between the seaway to the west and the north-to-south land routes of the interior of the peninsula; within the mountain belt lie valleys and basins of considerable productivity, capable of supporting fairly dense populations. The aloofness both of the land as a whole, and of its centres of settlement, has led to Albania being one of the least known parts of Europe, and within the post-war kingdom the primitive and the ultra-modern jostle one another. Thus there is a regular aeroplane service between the capital Tirana and the town of Koritsa, but over most of the country there are no roads, and the simple wooden plough, which scarcely does more than scratch the ground, is of archaic type. The language of the country is practically unknown beyond its own borders.

Structure and Relief.—Starting from this simple conception of Albania as consisting of a marginal lowland, crossed by powerful perennial streams, and a complex mountainous hinterland enclosing small fertile basins, the details of the picture may be filled in. To the north the Albanian Alps, built largely of massive limestones, form the outstanding feature. They have a general west-to-east direction, roughly parallel to the course of the Lower Drin, below the junction of the two streams of the Black and White Drin. The Black Drin is the effluent of Lake Okhrida, and flows northwards, draining a large part of eastern Albania, while the White Drin enters the country from Yugoslavia, flowing in a southerly direction. Below the confluence the river swings round at a sharp angle to cut through wild mountainous country, in a series of inaccessible gorges, on its way to the Adriatic. It receives a number of swift tributaries from the Albanian Alps, these also flowing in deep, steep-sided gorges, for the southern slopes of the mountains are remarkably abrupt and rocky. The result is that the actual valley of the Lower Drin is not, as one might suppose, a line of access to the interior, the only practicable route from the coast to the confluence of the two headstreams running well south of the river in the hilly Merdita region. No bridge crosses the Drin in its gorge section, and as it is too deep to be forded, the inhabitants usually cross it by swimming, supported by inflated skins. The fact is interesting as suggesting what is meant by difficulties of communication in Albania.

The Albanian Alps rise to heights of 6,500-8,500ft. above sea-level, and to the north-west, where limestones predominate, they are practically a continuation of the high karst of Montenegro. To the north-east, however, other rocks, particularly Palaeozoic schists, appear and the scenery is of a different type. The steep lower slopes are thickly wooded, for the region has one of the highest mean annual rainfalls in Europe. At the higher levels, however, where considerable plateau tracts occur, there are wide summer pastures. Though in the strict sense there is no permanent snow, patches linger throughout the summer, and a very slight change in the climate would give the chain a snowcap. It was heavily glaciated during the Ice Age, and the effects of ice erosion have been to accentuate its inaccessibility and high relief. Except on their margins the mountains are virtually devoid of permanent habitations, and thus at first sight they would appear to form an admirable boundary zone. But, as has been noted by travellers, parts of the higher levels swarm with herdsmen and their flocks during the summer season, and these mountain pastures are an economic necessity to the inhabitants of the lower grounds. Great difficulties have consequently arisen in demarcating frontiers, for the line of the water-parting, so often chosen as a basis, may separate a group from its pastures and thus inflict great hardship. In limestone regions, also, the water-parting may be very difficult to trace.

Westwards the Albanian Alps cease abruptly some 30m. from the Adriatic coast, giving place to quite a different type of country. Though much of it lies below 600ft., it is not a uniform plain, and there is a considerable belt of hills between Lake Scutari and the sea. The structure is, however, perfectly clear and simple. Low limestone hills indicate that the coastal chains of Dalmatia are continued here, but two separate facts introduce a new note. The first is that depression has taken place on a much greater scale than further north, and the second is that very extensive silting has occurred, so that the sunken hill-ridges are largely submerged beneath a mantle of recent deposits. Lake Scutari itself represents an area of depression in which the filling has been incomplete. The Drin, on emerging from its gorge, swollen by the water from the Albanian Alps, has great difficulty in finding its way through the maze of its own deposits and those of its tributary the Kiri. Up to the year 1858 it turned southward past Alessio (Lesh) and discharged its waters by a swampy, wooded delta just south of the port called by the Italians San Giovanni de Medua, and by the Albanians Shën Gjijn. In that year, during a period of high flood, it broke through to the Boyana, the effluent of Lake Scutari, and most of its water now follows this course, the older one carrying but a small part. This caused a rise in the level of Lake Scutari, with a flooding of parts of its margins,

and also obstructed the channel of the Boyana, formerly navigable, by the silt thus poured into it. As in all such changes of river course, deserted channels and pools were left to become breeding places of mosquitoes, and thus form foci of malaria.

South of this frontier zone of coastal lowland and inland mountain belt the conditions are much more complicated, both as regards geological structure and relief. The mere fact that the Drin, after a lengthy course as the Black Drin in the interior, should cut its way through the mountains in a gorge more than 3,000ft. deep, and over 30m. long, is sufficient to suggest that there have been earth movements on a considerable scale here. So far as geographical effects are concerned, however, the matter may be simply put. The course of the Lower Drin marks a change in the direction of the mountain folds, associated with changes in their characters. The outer or coastal folds have sunk, and at the same time rocks from the west have been thrust over them. The inner folds have been elevated, and as a result their surface rocks, including tertiary sandstones and Cretaceous limestones, have been for the most part worn off, exposing the deeper beds, mainly serpentines, below. These serpentines give rise to rounded land-forms, far less repellent than massive limestones, even though the elevation is considerable, a number of crests rising above 6,500ft. with a maximum of nearly 9,000ft. The region has also been cut up by river action so that it is by no means uniformly high, but encloses small plains whose floors in some cases sink to only some 650ft. above sea-level.

South of the Semeni the low ridges rise to greater heights and the limestones reappear beneath the sandstones. Still further south, beyond the River Viossa, the elevation increases to over 6,000ft., the limestones are fully developed, the sandstone covering disappears from the crests, though it remains in the intervening furrows, and the lowland gives place to the mountainous Epirus region, continued beyond the frontier into Greece. The vegetation undergoes a corresponding change, woods tend to disappear, and the summits are clothed with scanty herbage, again forming summer pasturages. This type of country is continued southward into Greece, and frontier lines are difficult to draw, for the whole tract is the natural home of wandering shepherds. No notable difference of elevation separates this littoral Epirus area from the mountain zone of interior Albania, but it is still possible to distinguish between the two because of the great simplicity of structure of the western folds.

From the western shores of Lake Okhrida towards the Lower Drin there extends northwards a mountain belt consisting of a series of blocks separated by mountain passes. This forms a central backbone repelling settlement to its margins. It is highest to the south where also it forms a single chain, and becomes lower towards the north where it tends to consist of rows of hills rather than of a single ridge. Finally it merges into the complex hilly country of the Merdita, south of the Lower Drin, where settlement becomes possible on the flanks of the hills as well as in the intervening valleys. Except in the extreme south, most of this central hill belt is heavily wooded, especially with beech. Above the tree limit occur the usual high pastures.

At either side of this chain lie long furrows, each consisting of a succession of basins and gorges, and forming one of the most characteristic features of the country. The eastern furrow is traversed by the Black Drin, and is bounded by another mountain belt on its eastern side. It might be supposed, therefore, that this mountain belt would form the eastern frontier of Albania with Yugoslavia. But this is only the case to a limited extent, for south of the town of Dibra, on the Black Drin, the Yugoslav frontier is pushed westwards, and includes that town, a part of the river and the greater part of Lake Okhrida. This is but another illustration of the difficulty of drawing satisfactory frontiers in the Balkan peninsula. The difficulty here depends on the peculiar topography which is itself a result of recent earth movements. It is a characteristic feature of Macedonia that large depressed basins occur which, even when they are strung along the same river system, are separated physically from one another by mountain sills, cut through by the river in gorges. Because of these sills it happens frequently that basins belonging

to separate river systems are in closer touch with one another than those linked by a single river. The Black Drin shows very markedly this feature of successive basins and gorges, the basins being largest to the south, and smaller towards the north. The largest is that which is mainly submerged beneath the waters of Lake Okhrida. It is a general rule in Albania that, as compared with Macedonia, the basins are small, and thus only moderately productive, and not capable of supporting a dense population. At the same time the intervening gorges tend to be longer and more forbidding, and the possibility of linking effectively successive series of basins by transverse routes is much less notable. These differences have had a cumulative effect on the inhabitants of the two areas, and the present frontier, which assigns the greater part of the larger southern basins to Yugoslavia, the power which holds the adjacent section of Macedonia here, and the smaller, more northerly ones to Albania, is drawn mainly on an ethnic basis, racial distribution here being a reflection of the topography.

Some of the basins on the course of the Black Drin may be noted. The largest, as just stated, is occupied by Lake Okhrida, of which only the south-western corner falls in Albania. Here lies the settlement of Pogradec. Still further south there lies a large basin containing the town of Koritsa, but this is best considered with the western furrow rather than with that of the Black Drin. On emerging from the lake that river passes through a heavily wooded gorge to emerge at the basin of Dibra. Though most of this basin lies in Yugoslavia, its Albanian side is also capable of settlement. A low ridge separates this basin from that of Pehskëpi, further north, and the alternation of basin and sill is continued to and even beyond the confluence of the Black and White Drin. In each basin there tends to be a market centre, but the point of importance is that the floor of the whole basin is capable of yielding cereals, especially maize and wheat, so that each forms a centre of settlement, more or less isolated from its neighbours, and necessarily self-sufficing.

To the west of the central mountain belt lies the second furrow, differing in several respects from that of the Drin. Though bounded on the west by the hill belt which forms the inner margin of the coastal lowland, it lacks the continuity given to its easterly counterpart by the Black Drin. A belt of highland forming the water-parting between the Upper Mati and a right-bank tributary of the Shkumbi divides it into a northern and a southern section, drained respectively by the Upper Mati and the Upper Shkumbi. North and south of this wooded and impassable highland passes permit communication with the Black Drin furrow, downstream from Dibra on the one hand, and in the Lake Okhrida area on the other. The latter line is particularly important as it was followed by the Roman Via Egnatia which passed from Durazzo to Elbasan, placed where the Shkumbi emerges from the hill country, and then by way of the basin traversed by that river to the shores of Lake Okhrida, which was rounded to the north. The existence of this route shows that the Shkumbi furrow is much less isolated than parts of the Drin furrow.

The headstream of the Shkumbi approaches very closely the valley of the Devoli, one of the two feeders of the River Semeni. The Devoli drains the basin of Koritsa, to the south of Lake Okhrida, and may be said to mark the region of convergence of the two furrows, the eastern and the western. Koritsa is a fairly important route centre, being connected southwards through Albanian Epirus with Yannina in Greek Epirus, eastward with Kastoria in Greek Macedonia, and also by the Devoli valley with the coastal lowland as with Durazzo via Elbasan and with Valona. To the south-west of the Koritsa basin lies the smaller one of Kolonja, traversed by the Osum river, the other feeder of the Semeni.

Climate and Natural Vegetation.—The climate of Albania may be briefly dismissed. The coastal lowland, together with the littoral part of the Epirus region, has the typical Mediterranean climate, with summer drought accentuated by high summer temperatures. But this type has a limited distribution. Even in the Epirus region the elevation brings changes, diminishing the heat of summer and slightly increasing its rainfall. The southern part of inner Albania, at least in the basins, shows the modified

Mediterranean or Macedonian type. The summers are hot, apparently even hotter than in the lowland, but winter frosts occur.

The natural vegetation reflects these climatic conditions. Near the coast the characteristic Mediterranean scrub or *maquis* occurs, though this has been largely cleared. It had always a somewhat limited distribution, and the most widely distributed plant association in the south is oak wood, or rather oak scrub-forest. The oaks are of the evergreen, drought-resisting type, and in addition to their value as sources of fuel are important in the low grounds as furnishing in their leaves and shoots supplementary winter fodder. Even cattle and horses eat oak leaves in Albania. To the north, with the heavier rainfall, the oak woods give place to luxuriant mixed forest, with beech as a predominant element, mingled with pines and firs.

People.—The inhabitants are mainly Albanians, with a certain admixture of Vlachs, especially in the Epirus region, and of a very few Serbs and Bulgars. But not all the Albanians live within the confines of the country. A number estimated at 87,000 live in southern Italy and Sicily, whither their forefathers fled from the Turks in the 15th and 16th centuries. Some 50,000 are found in the United States, many emigrants leaving Epirus, a region of poverty. As in other parts of the peninsula, emigration is often temporary, the travellers returning when they have amassed a certain amount of money. In addition roughly a million of Albanians live in Greek Epirus, Macedonia, and Kosovo, outside the frontier.

The Albanians have retained their original language, and, though dialects occur, the differences are said not to be so marked as to make mutual comprehension impossible. They are divided into Ghegs to the north of the Shkumbi line and Tosks to the south, the latter being apparently the more advanced. Some 69% of the total are Muslims, this being an effect of Turkish rule; monogamy is, however, the rule, and the status of women is higher than in most Muslim countries. About 10%, mostly living in the north, are Roman Catholics, while 20%, mostly in the south, belong to the Albanian orthodox church. Religious differences count for nothing as such, but affect political and social relations.

From the psychological standpoint the Albanians, about whose characteristics much has been written, may be said broadly to show the features common to isolated mountain folk. As is frequently the case with such stocks their virtues are apt to be more highly estimated by strangers than by those with whom they come in daily contact. Theft and cold-blooded murder are not crimes, either in the estimation of the individual or of his fellows, but a breach of the plighted word or a violation of the duties of hospitality cuts a man off from his family group, and adultery is uncommon. The blood-feud or vendetta, almost inevitable in a country of such loose organization, has been in the past a scourge, and there are said to be still, at least among the Ghegs, groups which hold that the death, even the accidental death, of a kinsman can only be wiped off by the murder of the guilty person or one of his relatives. Associated with this is the strength of the *bessa* or pledge, which protects its holder absolutely. All women are protected by the *bessa*, and so also is any man accompanied by a woman. Boys under 16 years of age, ecclesiastics, and generally all those incapable of bearing arms, are also protected, while certain places, or routes, some occupations, such as irrigation works, and certain periods, confer similar rights.

Occupations.—The Albanians are almost entirely dependent on the land, carrying on a characteristic combination of pastoral

and agricultural occupations. Sheep form the major part of the flocks, and yield cheese, which forms an important part of the diet, and is exported on a considerable scale, as well as wool and skins. Goats are also reared, but the cattle are of poor breeds, yielding little milk. Oxen, with buffaloes in the swampy plains, are the plough animals. Religion excludes the thrifty pig, save among the Christian tribes, and meat of any kind is a luxury. Even the ewe's-milk cheese is too valuable to be used extensively, and the Albanians are mainly vegetarians, depending on maize bread with vegetables and whey. Horses, donkeys and mules are reared for riding and as pack animals.

It is calculated that only 7-9% of the surface is arable, but of this total only a small part, particularly in the north, is actually utilized. In the lower grounds all the characteristic Mediterranean fruit-trees, including olive, orange, lemon, fig, etc., can be grown, but the Albanian shows little aptitude for the more delicate operations of arboriculture. The vine is grown on a fairly large scale, especially in the south of interior Albania, and wine is made, but of a quality only fit for local use. Brandy is distilled from a variety of fruits, including mulberries, and alcoholism is said to be one of the curses of the country. Despite the presence of the mulberry, silkworm-rearing is only carried on a small scale. Rice is produced in the swampy parts of the lowland, and tobacco is fairly widespread, and forms an article of export.

Towns.—Tirana, the capital, is the largest town with 30,806 inhabitants, and is growing rapidly. It lies in a wide and fertile plain below a mountain chain. It was chosen as the capital as being central, capable of expansion, and sufficiently far from the frontier or the sea to be entirely secure from any sudden seizure or from bombardment. Koritsa, which is the third largest town in the country, is situated in a well-cultivated and prosperous area.

See Bourcart, *L'Albanie et les Albanais* (1921); Louis, *Albanien* (1927, bibl.); J. and C. Gordon, *Two Vagabonds in Albania* (1927). (M. I. N.)

Defence.—The liability of all Albanians for military service begins at the age of 17 and ends at the age of 50. All youths, on attaining the age of 17 must join local militia units; and at the age of 19 they are liable for 18 months regular military service. Thereafter, they are reservists. Conscripts are called up once a year only (in April); and the maximum (or normal) strength of the army is about 11,450 officers and men. There is a *gendarmerie* of 3,131 officers and men, a Frontier Guard of four Battalions, and a coastguard service flotilla of six motor launches. The strength of the Militia is about 18,000. There is no air force.

See also the League of Nations *Armaments Year-Book*, 1928. (X.)

SOCIAL AND ECONOMIC CONDITIONS

According to whether they live north or south of the River Shkumbi, the Albanians are called Ghegs and Tosks, the latter having attained a more advanced state of civilization. The social organization of Albania, with its clans and tribes, recalls that of feudal Europe. The cohesion of the Albanian family is very remarkable.

Albania is divided into nine prefectures, called after the principal centres of population:—Argyrokastron, Berat, Dibra, Durazzo, Elbasan, Koritsa (Korça), Kosovo, Scutari (Shkodra), Valona. In 1923, 562,010 of the population were Muslims; 169,000 Orthodox Greek; and 85,600 Catholic. The Muslims, who represent 69% of the population, are in the majority in all prefectures, except in that of Argyrokastron, where the majority is Orthodox, and in that of Scutari, where Catholicism is predominant. Orthodox Christians are numerous in the regions of Koritsa, Berat and Valona, while the prefectures of Dibra, Durazzo, Elbasan and Kosovo are almost entirely Muslim.

The principal towns, in order of importance, are: Tirana, 30,806 inhabitants; Scutari, 29,209; Koritsa, 22,787; Elbasan, 13,796; Argyrokastron, 10,836; Berat, 10,403; Valona, 9,100; Durazzo, 8,739; Kavaja, 8,308.

COSTUME, THE DISTINGUISHING
FEATURE OF WHICH IS THE WHITE
PLAITED PETTICOAT

Religion.—The Albanians are extremely tolerant in religious matters. In 1923, the Muslim Congress at Tirana broke with the Caliphate, and proclaimed the religious autonomy of Albanian Muslims. After the Congress of Berat in 1922, the Albanian Orthodox Church constituted itself an independent Church, with the consent of the Patriarch of Constantinople. This Church has four metropolitans, at Durazzo, Berat, Argyrokastron and Koritsa. At Scutari the Catholics have an apostolic delegate and an archbishop. The country is divided into five Catholic bishoprics.

Education.—Under the Turkish domination, which prohibited teaching in the Albanian language, the Albanians remained in ignorance. The new State has succeeded in creating public instruction of all degrees. There are now in Albania 440 primary schools; 14 continuation schools; a teacher's training college at Elbasan; a school of agriculture at Lushna; a technical school at Tirana; an Albanian college at Scutari; and a French college at Koritsa.

Finance.—Albania is economically a backward country, and the State revenues, about 23,000,000 gold francs in 1927, are hardly sufficient to meet the cost of administration and the still rudimentary organization of public services. Its economical development was only possible with the aid of foreign capital. The Albanian Government met this need by entrusting in March 1925 to an Italian financial group the foundation of the National Bank of Albania and of the Corporation for the Economic Development of Albania.

Production.—Albania is a primitive country. Almost the whole population is engaged in agriculture and cattle-raising. Each household attempts to produce all the necessities of life for its own purposes, including flax, wool and leather, for clothing.

Albania is a mountainous country, a great part of its area being over 3,000 ft. above sea-level, the north and south offering vast districts unfit for cultivation. But the central region, the littoral, the shores of the great lakes, together with many wide valleys and high plateaus in the mountain districts, can be cultivated. The coast region is indeed very fertile, but it is for the greater part uncultivated, and indeed uninhabited, on account of the marsh-fever arising from the undrained marshes. In northern and central Albania, only about one-tenth of the arable land is under crops. In the northern mountains, land is held in common by families, the pastures being the collective property of the tribes. In the centre are found the large estates of the Albanian beys. The State moreover possesses a vast stretch of land in this region. South Albania is the best cultivated region.

Albania possesses vast forests of oak, walnut, chestnut, elm and plane trees, and in the high regions forests of beech, pine and fir. These forests are almost exclusively owned by the communes and by the State. In 1923 the Germans began a timber industry in the forest of Mamuras, north of Durazzo. Later on the Forestry Concern of the Italian State Railways was authorized to survey and to utilize the forest resources of the country.

Mines.—The mineral wealth of Albania, thought to be considerable, is not yet exactly known, no geological survey having yet been made. The results of the investigations made by the Austrians during the War have not been published. Almost the whole strip of coastline, about 40 m. wide, shows indications of the presence of hydro-carbons. Asphalt and bitumen are worked at Selenitza, near Valona, by a formerly French, now Italian, company. Petroleum concessions were granted to the Anglo-Persian Oil Co., to the Italian State Railways connected with the Standard Oil Co., and to the French *Crédit Général des Pétroles*. Coal seams exist in the regions of Tepeleni, Koritsa and Tirana; and there is iron in the basin of the Fani, near Scutari, and in the Tepeleni district.

Communications.—The ports of San Giovanni di Medua, Durazzo and Valona are good natural harbours, but they have not

BY COURTESY OF AMERICAN WOMEN'S HOSPITAL
A CORNER OF ELBASAN. A TOWN OF 13,000 INHABITANTS IN ALBANIA ON THE ANCIENT ROMAN ROAD BETWEEN DURAZZO AND OCHRIDA

been developed. With the exception of the Bojana, which is the outlet of the lake of Scutari to the Adriatic, there are no navigable rivers. Since the recovery of her independence, Albania has begun to construct much-needed roads. In 1925 there were about 720 m. available for motor traffic. There are no railways of normal gauge, though during the War the Austrians constructed "Decauville" lines from Scutari to Durazzo, Lushna and Berat, with branches to Tirana, Elbasan and Fieri. These lines still exist for the most part, but need repair. The line from Durazzo to Tirana is used for the carriage of materials needed for the repair of that route. Early in 1925 a German, now Italian, aeroplane service was started between Scutari, Tirana, Koritsa and Valona.

The Corporation for the Economic Development of Albania, supported by the Italian Government, has given Albania a 40 years loan of 50 million gold francs, guaranteed by the receipts of the Albanian customs and monopolies of salt, matches, cigarette paper and playing cards. The Italian Government has guaranteed the corporation the payment of the annuities of the loan. The money is to be used for important public works, as roads, bridges, harbour works at Durazzo, public buildings, and later on for the drainage of the large swampy malarious areas on the coast.

Trade.—The trade balance has much improved in recent years. While in 1920 the imports amounted to 17.5 million gold francs and the exports to 1.5 million only, the figures of 1926 reached 24.8 million (imports) and 12 million (exports). The imports, which consist principally of textiles, cereals, groceries and metals, come chiefly from Italy (67%) and Greece (12%). The greater part of the exports, consisting chiefly of live animals and animal food, cereals, raw hides and wood, go to Italy (45.8%), Greece (32.8%) and America (16.7%). The heavy trade deficit has been compensated to a large extent by remittances from Albanian emigrants in the United States.

The maritime communications consist of two Italian steamship lines.

Currency.—Till 1926 Albania had neither metallic nor paper money of her own. The unit was the gold franc, but payments were made in napoleons (20-franc gold pieces and 8-florin Austrian gold pieces) and in crowns (silver Austrian money). In Sept. 1925 there was formed the National Bank of Albania, with a capital of 12.5 million gold francs, of which 51% was subscribed by an Italian group. The National Bank created a gold currency with the Albanian or gold franc as a unit, and has issued bank-notes (whose circulation amounted in 1927 to nearly 3 million gold francs), exchangeable for gold, and gold, silver, nickel and bronze coins. The Bank has also established general warehouses for credit purposes for the import and export trade.

MEDIAEVAL AND MODERN HISTORY

After the division of the Roman empire, northern and southern Albania became the Byzantine provinces of Dyrrachium and Nikopolis. Overrun by the Goths in the 4th and 5th centuries, they were reconquered by Justinian in 535. In 640 northern Albania was invaded by the Serbs. In 861 the Bulgarians conquered southern Albania, defeated the Serbs (893–927) and established themselves (976–1014) in the greater part of the peninsula; but in 1014 the emperor Basil II. reconquered southern Albania, which remained under Byzantine rule until 1204, when Michael Comnenus, of the imperial family, founded the independent *Despotate* of Epirus, which included southern Albania, Acarnania, and Aetolia. In 1318 the Despotate passed to the princes of the house of Orsini, who ruled it until 1358. Meanwhile the Sicilian kings acquired and held central Albania (1271–1368). In 1180 the Serbs had re-installed themselves in the provinces of Scutari and Prizren, and Stefan *Dushan* (1331–58) included all Albania in his ephemeral empire. Large numbers of Albanians under Jin Bua Spata and Peter Liosha emigrated southward before *Dushan's*

hordes, took Yannina and Arta, and penetrated as far as Acarnania and Aetolia (1358), while colonies were established in the Morea, Attica and Boeotia.

After the death of *Dushan* Albania fell under the rule of native chieftains; but a Norman knight named Balsha, who had served under *Dushan*, established a dynasty at Scutari (1366) and induced the chieftains to co-operate under his leadership against the Serbs and Bulgarians. The power of the Balshas was, however, short-lived. At the close of the 14th century the Venetians established themselves at Durazzo, Scutari, and Antivari, and in 1421 the dynasty came to an end.

Period of Turkish Rule.—The advance of the Turks, who captured Yannina in 1431, reunited the Albanian chieftains (1444-66) under the immortal George Kastrioti of Kroia (see SKANDERBEG), and thereafter under the Venetians. But in 1478 Kroia surrendered Scutari in 1479, Durazzo in 1502, and in 1571 Antivari and Dulcigno, the last Venetian possessions in Albania. Many Albanians fled with their Venetian allies to Dalmatia and Italy. Although more than half the Albanian race abandoned Christianity—in the lowlands that it might enjoy equality with the Turks, and in the north-eastern highlands that it might obtain their support against its hereditary foes, the Slavs—Ottoman sovereignty was never effectively established, and against it the Albanians intermittently revolted. In about 1760 Mehmed Bushati, pasha of Scutari, rallied the northern clansmen and threw off Turkish suzerainty. His son, Mahmoud, *the Black*, routed three Turkish armies, but with the defeat of his grandson Mustafa, in 1831, the power of the Bushati was broken. Meanwhile, in southern Albania, the able Ali Pasha of Tepelen (b. about 1750), by a combination of cunning and brutality, established a virtually independent state with Yannina as its capital, and maintained direct relations with foreign Powers, but was overthrown by a Turkish army in 1822.

The revival of nationalism in Greece, Bulgaria and Serbia, coupled with the decline of the Turkish empire, induced the Albanians to prepare for and to seek autonomy within the empire while availing themselves of its protection until they were prepared for independence. In 1879 the Porte sought to turn Albanian nationalism to its advantage by encouraging the formation at Prizren of the *Albanian League*, which opposed with some success the cession of Albanian territory, as provided for by the Treaty of Berlin, to Montenegro and Greece. Once the *League* had fulfilled its purpose the Porte suppressed it, although not without much bloodshed. But Albanians at home and abroad continued to work clandestinely in the national cause. In 1908 they threw in their lot with the Young Turks—whose success was due largely to their support—in the hope that in consequence they would obtain autonomy and educational liberty. The new régime proved, however, infinitely worse than previous conditions, and the Albanians rose in revolt against Ottomanization. Throughout 1910-11 they struggled unsuccessfully, but in 1912 a general rising was successful; the vilayet of Kosovo was liberated, Monastir threatened, and in August the Turks were obliged to grant autonomy to Albania, which was to include the vilayets of Scutari, Kosovo, Yannina and Monastir. But the Balkan States had envisaged the partition of Albania between them and hastened to precipitate war with Turkey. The Albanians, wishing neither to be classed as Turks and share their fate, nor to facilitate the overthrow of their protectors, and without any central administration to guide them, remained neutral except at Yannina and Scutari which were vital to their national existence. On Nov. 28, 1912, Ismail Kemal Vlora, diplomatically supported by Austria-Hungary and Italy, who were opposed to the access of any third Power to the Adriatic, proclaimed Albanian independence at Valona. But Russia and France supported the Balkan allies, and a general European war was perhaps only averted by British arbitration. The solution of the problem was entrusted to a Conference of Ambassadors in London, which acknowledged the principle of Albanian autonomy on Dec. 20, and on July 29, 1913, declared Albania an independent sovereign State; but its boundaries included less than half the Albanian race.

The Albanian State.—Prince William of Wied, selected by the Powers to rule Albania, landed at Durazzo on March 7, 1914; but

the machinations and the intrigues of various neighbouring States rendered his position untenable. Unable to extend his authority into the interior, he left Albania on Sept. 3, although he did not abdicate. Meanwhile, to resist the incorporation of southern Albania in the new State, Greece instigated during February the constitution of a "Provisional Government of Autonomous Epirus" supported by Greeks masquerading as insurgents. The international situation prevented the Powers from interfering, and anarchy continued until Greece was authorized officially to re-occupy southern Albania in the autumn. Italian troops occupied Valona in Dec. 1914, and in 1916 the whole of southern Albania, except the Korçha region, which was occupied from Salonika by the French, who established an autonomous administration. Early in 1915, the Serbs and Montenegrins occupied northern and central Albania after severe fighting, but after their defeat by the Austro-Bulgarian armies these regions were occupied by the latter in 1916. Albania had no central government, although Essad Pasha posed as its president, and local policies were pursued. On June 3, 1917, General Ferrero proclaimed the independence of the whole of Albania under Italian protection, thereby repudiating those clauses of the Pact of London (1915) which provided for its partition.

Albania after the War.—After the Armistice the Italians occupied most of the country, the French remained at Korçha until June 1920, the Yugoslavs occupied north-eastern Albania, and at Scutari an inter-allied administration, the successor of the international administration temporarily established in 1914, governed until Feb. 1920. In Dec. 1918 a National Assembly at Durazzo elected a provisional government and delegation to the Peace Conference. In Feb. 1920 the Albanians, exasperated by Italy's apparent intention to remain in occupation, her readiness to sacrifice Albanian territory to Greece and Yugoslavia for advantages elsewhere, and the refusal of the Yugoslavs to withdraw while the Italians remained, formed a fresh government at Lushnja with a mandate to obtain the restoration of independence, elected a council of regency composed of a representative of each of the four religious sects, and selected Tirana as the capital. In June the Albanians drove the Italians into Valona. The latter, appreciating the folly of defeating their own ends by alienating Albanian good will, thereupon recognized the Albanian Government (Aug. 2, 1920) and evacuated the country. The Yugoslavs, now in turn asked to withdraw, advanced on Tirana; but the Powers intimated their displeasure, and the Yugoslavs thereupon withdrew to their original positions. While ostentatiously declaring for the re-establishment of Albania as delimited in 1913 that they might not prejudice their case against Italy in the Adriatic dispute which was settled by the Rapallo Treaty (Nov. 1920), the Yugoslavs worked surreptitiously to acquire north-eastern Albania for strategic reasons. A "Mirdite Republic," proclaimed at Prizren (June 1921), was unsupported outside Yugoslavia; and a serious invasion of Albania, with the intention to detach the north and confront Europe with an accomplished fact, was frustrated by the intervention of the British Government (Nov. 7), which convened a meeting of the Council of the League of Nations, of which Albania had become a member on Dec. 17, 1920. Meanwhile the Conference of Ambassadors finally overruled all claims to Albanian territory by confirming (Nov. 9, 1921) the 1913 frontier with the exception of minor rectifications, at the same time declaring that the integrity of Albania's frontiers was necessary to the strategic security of Italy. The frontier question was finally closed on Aug. 2, 1926, by the signature in Paris of a protocol, and in the meantime the rectifications caused much tension between Albania and its neighbours.

Internal Politics.—On Dec. 25, 1921, Albania's sixth post-war cabinet took office; it included Djafer Ypi (Premier), Fan Noli (Foreign Affairs), and Ahmed Zogu (Interior). With the exception of an irredentist insurrectionary movement in March, 1922, perfect tranquillity reigned throughout the country until June 1924. Zogu became premier in a reconstituted cabinet in Dec. 1922, and with the assistance of foreign advisers much progress was made towards consolidation and development. But Albania was hopelessly handicapped financially, not being supported, as

other Balkan States had been, by a foreign Power; and rumours of disturbances deliberately spread by interested parties discouraged foreign private enterprise. Late in 1923 Zogu was accused by the Democratic Party of obstructing, in the interests of the land-owning classes, various progressive and agrarian reforms, and by the irredentists of pro-Yugoslav tendencies because he turned his back upon irredentist dreams. His resignation in Feb. 1924 did not pacify his opponents, who contended that his influence remained. During June northern and southern Albania rose against him and his colleagues, who were compelled to seek refuge abroad. Mgr. Noli's revolutionary Government succeeded in balancing the budget, due to the ability of M. Gurakuchi (Finance), but otherwise accomplished little. Meanwhile, Zogu, who had retired to Belgrade, organized with Yugoslav assistance a well-equipped force, with which he returned to Albania and expelled Noli.

The Albanian Republic.—On Jan. 22, 1925, a National Assembly voted the proclamation of a republic, and on Feb. 1, Zogu was elected president for seven years, the regency being abolished. By a generous attitude towards political opponents, Zogu consolidated his position, at the same time making it clear that, although grateful for Yugoslav support, he did not intend to become Yugoslavia's vassal. During Sept. 1923 negotiations with Italy for a loan were concluded and a national bank established, an Italian financial group being the principal shareholder. Relations with Greece, strained over the Turko-Greek exchange of populations, in which Greece sought to include the Muslim Albanians of Epirus, were improved through the mediation of the League; and a conciliatory policy towards Yugoslavia improved relations with that country, although proposals for the conclusion of a pact of friendship and security were received unfavourably in Belgrade as had been previous proposals. Zogu, although anxious to consolidate his position by obtaining support from a neighbouring Power without sacrificing independence, and although doubtful of the competence of the League—which had failed in his predecessor's case—to prevent his overthrow by bands from across the border, hesitated to turn to Italy, which had acquired already a commercial foothold in the country. But an insurrection in northern Albania in Nov. 1926, sustained from Yugoslavia, forced his hand. By the Treaty of Tirana, concluded on Nov. 27, Italy and Albania recognized that any disturbance directed against the *status quo* of Albania is opposed to their reciprocal political interests, and to safeguard it undertook to give their mutual support and cordial collaboration. This treaty, which was registered at Geneva on Feb. 8, 1927, with a supplementary letter explaining that Italy could not interfere in the external or internal affairs of Albania except at the latter's request, precluded further unsolicited interference from across the border and raised a storm of protest in Yugoslavia. Preparations in Yugoslavia to overthrow Zogu were reported by Italy during April 1927 to the Powers, and a grave international crisis was only averted by the pressure which they brought to bear. The arrest at Durazzo on May 22 of Djurashkovitch, an Albanian subject alleged to have been engaged in espionage for Yugoslavia, provoked a further crisis. The Yugoslav Legation maintained that it employed him as dragoman, and in an offensive note, to which Albania took exception, the Chargé d'Affaires demanded his immediate release. The Albanian Government refused to comply unless the offending note was modified. Thereupon the Yugoslav representative was withdrawn and diplomatic relations broken off, but through the intervention of the Powers the matter was settled by the simultaneous release of Djurashkovitch and modification of the note. In reply, it would seem, to the treaty of friendship signed by France and Yugoslavia on Nov. 11, 1927, a defensive alliance between Italy and Albania for 20 years was concluded at Tirana on Nov. 22, 1927. On Sept. 1, 1928, Ahmed Zogu (*q.v.*) was proclaimed king.

ALBANIA, the ancient name of a district in the eastern Caucasus, consisting, according to Strabo (xi. 4. 1-8), of the valley of the Cyrus (Kur) and the land lying between it and the Caucasus range from Iberia to the Caspian sea. The Albani inhabited also the mountain valleys and the land to the north. (Pliny vi. 39). Dionysius of Halicarnassus quotes a tradition that the name arose because the people were the descendants of emigrants from Alba in Italy. Strabo describes them as tall, well made, and in character simple and honest. They worshipped the sun and, more particularly, the moon, the latter being perhaps identical with the great Nature Goddess of Asia Minor (*see* GREAT MOTHER OF THE GODS). Old age was held in high honour, but it was sacrilege to speak, or even to think, of the dead. The people were nomadic and lived on the abundant natural fruits of the land. In Strabo's time they appear to have been ruled by a single king. The Albani became known to the Romans during Pompey's pursuit of Mithridates the Great (65 B.C.), against which they are said to have opposed a force of 60,000 foot and 20,000 cavalry. Pompey exacted from them a nominal submission, but their independence was not seriously affected by the Romans. In the reign of Hadrian their territory was invaded by the Alani (Th. Mommsen, *Provinces of the Roman Empire*, Eng. trans. 1886), and later they fell under the Sassanid rule. They were driven finally into Armenia by the Khazars and ceased to exist as a separate people. The district subsequently suffered under the successive invasions of Huns, Varangians (who captured the chief town Barda in the 10th century), and Mongols. (*See* CAUCASUS, *History*; ARMENIA.)

ALBANIAN LANGUAGE. This Indo-European language is spoken in the mountainous region north of Epirus, south of Montenegro, on the eastern side of the Adriatic, by rather less than a million persons, who have kept to their ancient speech as to their ancient ways.

Apart from a few fragments of the 15th century, the oldest texts belong to the 16th and 17th centuries so that all we have is a modern version not very remote from present day speech. It is therefore difficult to construct an accurate history of the language. From what period Albanian was spoken in its present area and whence it came, cannot be stated with certainty. There is no reason for holding that it came from Thrace and it probably is the continuation of a language which from early times was spoken in this area.

Albanian preserves a number of peculiarities indicating its Indo-European origin, such as the personal pronouns, *ty*, thou; *na*, we; *ju*, you; and verbal forms as *thom*, I say; *thotë*, he says; *thomi*, we say; *thonë*, they say.

It is now modern in type. The article follows the noun. The future is expressed by a periphrasis. I will work is *do të punoj*, literally, there is a will that I should work; or *kam me punue* = I have to work, as in the French, *travaillerai*.

A few indigenous words come directly from the Indo-European stock such as, in the northern dialect (called Guëgue) *dîmen* = winter, plural *dîmna*; and *ëmën* = name, plural *ëmna*. In Tosk, the southern dialect, these nouns vary in form because *n* between vowels becomes *r*, thus *dîmër*, *dîmëra* and *emër*, *ëmera*.

The bulk of the vocabulary consists of words borrowed from foreign languages, Albanian being thus a typical Balkan speech in which words have passed from one tongue to another so that we may speak correctly of a Balkan vocabulary despite the fundamental diversity of the individual languages.

Hardly any words can be definitely traced to ancient Greek, whose influence barely reached Albania in classical days. Latin, however, has had a strong influence even from early times and Romance scholars find Latin as well as Romance loan-words. Numerals like *pes* = five, and *dhet* = ten, have an indigenous appearance; but *katrë* = four, and *qind* = one hundred, are evidently from Latin. The Latin *amicus* is *mik*, *canis* (dog) is *gen. Këndo*, to recite or read comes from *canto*; as *livoj* = work, comes from *laboro*; and *kujtoj* = think, from *cogito*. Without words taken from Latin, the language would be seriously inadequate. It is a language of interest to the student, for we have a country reached by Roman civilization under the empire where the non-urban population preserved its own speech. The vocabulary is

full of Latin words while the grammar and pronunciation have remained constant to indigenous forms.

Many other influences have been at work on Albanian. Mediaeval and modern Greek have furnished many words, often by indirect routes. Other words are of Slav origin. Thus the word *lypset*—"it is necessary," was borrowed from Serbian, which in turn borrowed it from Greek.

ALBANUS LACUS (LAGO DI ALBO), a lake 12m. S.E. of Rome. It is at the bottom of an extinct crater, itself on the margin of the great crater of Albanus Mons (*q.v.*). Fed by subterranean springs, it is 560ft. deep and the banks 400ft. over water-level. An outlet was made in 398–397 B.C., because the Delphic Oracle said Veii could be taken only when the waters reached the sea; it is still in use and is rock-hewn, 1m. long, 6ft. high and 4ft. broad with vertical shafts and a sluice chamber. (See ALBA LONGA.)

ALBANUS MONS (mod. *Monte Cavo*), the highest point of the volcanic Alban hills, about 13m. S.E. of Rome, 3,115ft. above sea-level. It is on the inner crater rim, while Tusculum and Algidus Mons are on the earlier outer crater, about 7m. wide. Upon the Mons Albanus stood the temple of Jupiter Latiaris, where the annual festival of the Latin League was held.

Little was left of it even in the 17th century, and the charge generally brought against Cardinal York of having destroyed it to build the monastery on the summit cannot be maintained. It is very probable that it was not a large temple (of which indeed no traces have been found) but a precinct containing a number of small shrines. On the other hand, a little below the summit 16 large drums of columns, some four feet in diameter, were found, and probably belonged to some other temple. The road which ascended to the temple is still well preserved for the greater part of the way from Aricia, where it began. It was called Via Triumphalis, because minor triumphs were held on the Mons Albanus.

ALBANY, DUKES OF. The territorial designation of Albany was formerly given to those parts of Scotland to the north of the firths of Clyde and Forth. The title of duke of Albany was first bestowed in 1398 by King Robert III. on his brother, Robert Stewart, earl of Fife (*see* I. below); but in 1425 it became extinct. The dukedom was re-created, *c.* 1458, in favour of Alexander Stewart, "lord of Annandale and earl of March" (*see* II. below), whose son and successor (*see* III. below) left no legitimate heir. The title of duke of Albany was next bestowed upon Henry Stuart, commonly known as Lord Darnley, by Mary, queen of Scots, in 1565. From him the title passed to his son, James VI. of Scotland and I. of England. The title was by him given, at his birth, to Charles, his second son, afterwards King Charles I. By Charles II. it was again bestowed, in 1660, on James, duke of York, afterwards King James II. On July 5, 1716, Ernest Augustus, bishop of Osnaburgh (Osnabrück) (1674–1728), youngest brother of King George I., was created duke of York and Albany, the title becoming extinct on his death without heirs in 1728. On April 1, 1760, Prince Edward Augustus, younger brother of King George III., was created duke of York and Albany; he died without heirs on Sept. 17, 1767. On Nov. 29, 1784, the title of duke of York and Albany was again created in favour of Frederick, second son of George III., who died without heirs on Jan. 5, 1827. On May 24, 1881, Prince Leopold, youngest son of Queen Victoria, was made duke of Albany (*see* IV. below).

I. ROBERT STEWART (*c.* 1345–1420), duke of Albany, regent of Scotland, was a natural son of King Robert II. He was made high chamberlain of Scotland in 1382, and gained military reputation by leading several plundering expeditions into England. In 1389 he was chosen governor of Scotland by the estates; and he retained the control of affairs after his brother John became king as Robert III. in 1390. In April 1398 he was created duke of Albany; but in the following year his nephew David, duke of

Rothesay, the heir to the crown, succeeded him as governor, although the duke himself was a prominent member of the advising council. Uncle and nephew soon differed, and in March 1402 the latter died in prison at Falkland. It is not certain that Albany was responsible for the imprisonment and death of Rothesay, whom the parliament declared to have died from natural causes; but the scanty evidence points in the direction of his guilt. Restored to the office of governor, the duke was chosen regent of the kingdom after the death of Robert III. in 1406, as the new king, James I., was a prisoner in London; and he took vigorous steps to prosecute the war with England, which had been renewed a few years before. He suppressed a formidable revolt led by Donald Macdonald, second lord of the isles, who claimed the earldom of Ross and was in alliance with Henry IV. of England. The duke died at Stirling Castle in Sept. 1420, and was buried in Dunfermline abbey. His son, Murdac (or Murdoch) Stewart, succeeded him as duke of Albany and regent, but the dukedom became extinct at his execution in 1425.

See John of Fordun, *Scotichronicon*, continued by Walter Bower, edited by T. Hearne (1722); Andrew of Wyntoun, *The Orygynale Cronykil of Scotland*, edited by D. Laing (1872–79); and P. F. Tytler, *History of Scotland* (1850). *See* also Sir W. Scott's *Fair Maid of Perth*.

II. ALEXANDER STEWART (*c.* 1454–1485), duke of Albany, was the second son of James II., king of Scotland, by his wife, Mary, daughter of Arnold, duke of Gelderland. Created duke of Albany before 1458, he also received the lordship of the Isle of Man, and was afterwards captured by an English ship when journeying to Gelderland in 1468. He was soon released, and as he grew to manhood began to take part in the government and defence of Scotland, being appointed in quick succession high admiral, warden of the marches, governor of Berwick and lieutenant of the kingdom. He quarrelled with his brother, king James III., and carried on a series of intrigues with the English, who supported his pretensions to the Scottish crown. He was sentenced to death in 1483 during his absence in England. He died in France two years later.

III. JOHN STEWART (*c.* 1481–1536), duke of Albany, regent of Scotland, was born about 1481. In 1515, at the request of the Scottish Parliament, Albany came to Scotland, was inaugurated regent in July, and proceeded to organize resistance to the influence of England and of Margaret Tudor, the queen dowager, sister of Henry VIII. In August he seized the latter and her children at Stirling, and subsequently was occupied in suppressing the rebellion of the Homes, Angus (the second husband of Margaret), and James Hamilton, earl of Arran; Alexander, third lord Home, being beheaded in Oct. 1516. Albany was declared on Nov. 12 heir to the throne, and on June 6, 1517, he returned to France. In August he concluded the treaty of Rouen, by which the alliance between France and Scotland was renewed, and a daughter of Francis I. was to marry James V. Meanwhile disorders had broken out owing to the rivalry between Angus and Arran. Francis I. had secretly engaged himself to Henry VIII. not to allow Albany's departure from France, but he returned at the close of 1521 and immediately became the object of Henry VIII.'s and Wolsey's attacks. He reconciled himself temporarily with Margaret, supported her divorce from Angus, and was now accused by the English Government of harbouring schemes of marrying her himself. This was denied by the Scots, and Henry's demand for the regent's dismissal refused. War broke out in 1522, and in Sept. Albany advanced to within four miles of Carlisle with a large army. The Scots, however, showed unwillingness to fight outside their own frontiers, and Albany disbanded his troops and departed to France, leaving the borders exposed to the enemy. On Sept. 25, 1523, he once more landed in Scotland, bringing with him supplies from France and a considerable body of troops, and on Nov. 3, after an unsuccessful attack on Wark, retreated hastily, and quitted Scotland finally on May 20, 1524. On July 30 his regency was terminated by the declaration of James V. as king. Between 1530 and 1535 he acted as French ambassador in Rome, conducted Catherine de' Medici, his wife's niece, to Paris on her marriage to Henry (afterwards Henry II.) in 1534, and negotiated the marriage of James V.

The regent Albany was a singularly unfortunate commander in the field, but a successful ruler and administrator, and the Scottish court of session owed to him its institution. But he regarded himself more the subject of the king of France than of the king of Scotland, subordinated the interests of the latter state to the former, and disliked his official duties in Scotland.

IV. LEOPOLD GEORGE DUNCAN ALBERT (1853-1884), duke of Albany, youngest son of Queen Victoria, was born on April 7, 1853. He matriculated at Christ Church, Oxford, in Nov. 1872, and pursued his favourite studies of science, art, and the modern languages. In 1876 he left the university with the honorary degree of D.C.L. On coming of age in 1874, he had been made a privy councillor and granted an annuity of £15,000. He travelled on the continent, and in 1880 visited the United States and Canada. He was a trustee of the British Museum, a bencher of Lincoln's Inn, and continued to take an active part in the promotion of education and knowledge generally. On May 24, 1881, he was created duke of Albany, earl of Clarence, and Baron Arklow. On April 27, 1882, he married Hélène Frederica Augusta, princess of Waldeck-Pyrmont, and his income was raised by parliament to £25,000. His death at Cannes on March 28, 1884, was universally regretted. He left a daughter, born in Feb. 1883, and a posthumous son, Arthur Charles Edward, born on July 19, 1884, who succeeded to the dukedom of Albany, and who, on July 30, 1900, became duke of Saxe-Coburg on the death of his uncle. He abdicated on Oct. 22, 1920.

ALBANY, LOUISE MAXIMILIENNE CAROLINE, COUNTESS OF (1752-1824), eldest daughter of Prince Gustavus Adolphus of Stolberg-Gedern, was born at Mons on Sept. 20, 1752. In her youth she was a canoness of Ste. Wandru at Mons, but in her twentieth year she was affianced, at the instigation of the Duke of Berwick and with the secret connivance of the French court, to Prince Charles Edward Stuart, "the Young Pretender," self-styled Count of Albany. They were married at Macerata, near Ancona, on Good Friday 1774, and went to live in the old Stuart palace at Rome and later on in Florence.

The marriage was an unhappy one, and in Dec. 1780 Louise fled to a neighbouring convent and threw herself on the protection of her brother-in-law, Henry Stuart, Cardinal York. She had already in Florence formed the acquaintance of the poet Vittorio Alfieri, who now followed her to Rome. In 1784 a legal separation between the Count and Countess of Albany was arranged, and by Charles's death in 1788 Louise found herself free. In company with Alfieri (to whom rumour said she had been secretly married) she now visited Paris and London, and was cordially received at the English court, George III. granting her an annual pension of £1,600 from the privy purse. Returning to Italy, Alfieri and the countess settled at Florence, where the poet died on Oct. 9, 1803 and was buried in the church of Santa Croce beneath Canova's vast monument erected at Louise's expense. The countess continued to reside in the house on the Lung' Arno at Florence, where she held a salon frequented by scientists and men of letters. She died on Jan. 29, 1824 and was buried in Santa Croce.

The countess bequeathed all her property to the companion of her old age, the French painter, François Xavier Fabre, who ultimately gave the greater part of his legacy to the museum of his native town of Montpellier. Two excellent portraits of the Countess of Albany and of Alfieri, painted by this artist, now hang in the Uffizi Gallery at Florence.

BIBLIOGRAPHY.—See Vernon Lee, *The Countess of Albany* (1884); Marchesa Vitelleschi, *A Court in Exile*.

ALBANY, a municipal town in the county of Plantagenet, on Princess Royal harbour, itself an interior basin of King George sound, on the most southerly stretch of the coast, and towards the south-west corner of West Australia. The coast-line, here largely composed of granite, has sunk in recent geological times, giving rise to magnificent inlets which, however, wave action has to some extent already modified by erosion and the deposition of sand. First occupied in 1826, it was later (1889) connected by rail with the existing West Australian railway system and ultimately became the southern terminus of the Great Southern railway. Albany is 352m. distant from Perth by rail. Its fine and equable

climate (mean annual temp.: 58.6°; mean annual rainfall: c. 30") and its scenery brought it into prominence as a summer and health resort, and for long it was the port of arrival and departure for the mail steamers. A coaling station, importing Newcastle (N.S.W.) coal was established; and industries began to rise and flourish. The development of the ports of Fremantle and Bunbury; the substitution of locally mined (Collie) coal for imported coal; the loss of economic hinterland through the development of the State railway system, and the loss of passenger traffic owing to the completion of the west-east trans-continental line have severely affected Albany which is at present suffering a decline; but with the development of the promising south-western region of the State it can hardly fail to progress.

ALBANY, a city of Georgia, U.S.A., 150m. S.S.E. of Atlanta, on an elevated plateau at the head of navigation on the Flint river; the county seat of Dougherty county. It is served by the Atlantic Coast Line, the Seaboard Air Line, the Central of Georgia, the Georgia Northern, and the Georgia Southwestern and Gulf railways. The population in 1920 was 11,555; 6,144 negroes; 1930, 14,507. It is the commercial and social centre of a region which formerly was devoted to cotton raised by negro tenants on large plantations, but, since the boll weevil reached it about 1915, the region has been in process of transformation into small farms with diversified crops. Cotton is still a profitable crop, when the new intensive methods are applied, but other products are increasing rapidly in importance, especially pecans, bright leaf tobacco, peaches, peanuts, sweet potatoes, water-melons and cantaloups, hogs, poultry, berries and vegetables. There were over 70,000 acres planted in paper-shell pecans in 1927.

The city has railway repair shops, cotton gins, tobacco warehouses and several co-operative marketing associations. The State Normal and Agricultural college for coloured students is here. Four miles south are mineral springs with a high percentage of radioactivity.

Albany was settled in 1836; planned in 1837 by Nelson Tift, from Connecticut; and incorporated in 1838. The commission form of government was adopted in 1924.

ALBANY, the capital of the State of New York, U.S.A., a city, a port of entry, and the county-seat of Albany county; on the west bank of the Hudson river, below the mouth of the Mohawk, 145m. N. of New York city; at the cross-roads between Boston and Buffalo, and between Montreal and New York. It is served by the New York Central, the Delaware and Hudson, the West Shore, and Boston and Albany railways; by the steamboat lines on the Hudson, and is a terminus of the State barge canal system. The area is 19.1 sq. m. The population in 1920 was 113,344, of whom 87,779 (an unusually large proportion) were natives of the state, and 17,695 were foreign-born; in 1930 it was 127,412.

Albany lies picturesquely, on a series of hills rising sharply from the river. Fine specimens of the Dutch and later colonial architecture are still standing. The Schuyler mansion (built 1761) was dedicated in 1917 as a State historical monument. The Van Rensselaer manor-house (1765) was moved in 1893 to the campus of Williams college, Williamstown (Mass.). On a commanding site of 7.84 ac. stands the State Capitol (300 by 400 ft.) of Maine granite, which was built (1867-98) at a cost of \$25,000,000. Across the square is the beautiful colonnaded State education building, which also houses not only the State Department of Education, but also the State library (established 1818) of 630,000 vols. and the State museum, which has a fine collection of Indian relics. The present city hall (erected 1882), the fifth which the city has used, is a French Gothic structure of pink granite. A large State office building has recently been erected (1927). Many of the schools, banks, hotels, clubs, and churches have architectural beauty and dignity. The New York State National Bank (1803) is probably the oldest building in America continuously used for banking purposes. There are 20 parks, of which Washington and Lincoln are the largest. A zoning ordinance was adopted in 1924 as a foundation for a comprehensive programme of building and improvement. The assessed valuation of property in 1926 was \$187,331,711. Con-

verging railways, water routes, and highways, together with a population of 30,000,000 within a radius of 200m. make Albany an important distributing point. As a transfer point for railway express it ranks second in the country; for mail, third. Traffic facilities were greatly improved by the New York Central's construction of the "Castleton cut-off" (opened 1924), which diverts rail traffic from the steep grades and congested trackage at Albany across a new bridge 10m. below the city. The same company has also built a vast terminal classification yard at

A FREIGHT AND A PASSENGER BOAT AT THE ENTRANCE OF THE ERIE CANAL INTO THE HUDSON RIVER AT ALBANY, N.Y., AFTER A PRINT PUBLISHED IN 1825, AT THE TIME OF THE COMPLETION OF THE CANAL

Selkirk, west of the river, which eventually will have a capacity for 20,000 cars. Albany has a municipal airport, the Quentin Roosevelt field; and the deepening of the Hudson (authorized 1925), to give a 27 ft. channel from New York city, will make it virtually a seaport. The Albany port district, embracing the city of Albany, the city of Rensselaer, and adjacent lands and water in the Hudson river, is in charge of a commission appointed by the governor. Ground was broken for port development in 1926.

Albany has many and diverse industries. It had 230 factories in 1927, with an aggregate output valued at \$58,185,252, and products ranging from such staples as stoves, chemicals, textiles, and paper, to billiard balls, checkers, and dominoes, axle-grease, paper towels, college caps and gowns, and college pins. About 1,100 men are employed in printing plants. Albany is an important educational centre. The public school system includes 27 elementary schools, vocational schools for boys and girls, junior high and high schools. The Catholic system consists of 18 parish schools (including four high schools), two academies, and two institutions of college grade. There are several private academies. The State college for teachers (opened 1844) had an enrolment of 2,275 in 1926-27. The professional schools of Union university, which has its undergraduate college in Schenectady, are situated here: viz., the Albany college of pharmacy (established 1881); the Albany law school (1851); and the Albany medical school (1839). The Dudley observatory, founded in 1853 as the result of an abortive attempt to establish a national university in Albany, is also affiliated with Union university. Training schools for nurses are maintained by four hospitals. The State library school, the first ever established for the professional training of librarians, was opened in 1887 at Columbia university, and in 1889 was transferred to Albany as an adjunct of the State library. There are three daily papers; the *Knickerbocker Press* (1842); the *News and Journal* (1922), and the *Times-Union* (1853).

Albany was probably the second permanent settlement within the borders of the 13 colonies. Its authentic history dates from 1614, when the agents of the United New Netherland company built a small fort on Castle (now Westerlo) island, which they occupied for three years as a trading post. In 1624 colonization was begun by the newly-organized Dutch West Indian company. Eighteen families of Dutch Walloons arrived; Fort Orange was built on a hill near the present site of the Capitol; and the little settlement around it became known as Beverwyck. In 1629 the Dutch Government granted to Kiliaen van Rensselaer, a diamond merchant of Amsterdam, a large tract of land (ultimately 1,093 sq. m.) on both sides of the river, centring at Fort Orange, for a patroonship. His grant was named Rensselaerswyck. The colonists he sent over were capable and industrious, and the settlement

prospered. In 1652 Peter Stuyvesant, after a lengthy controversy with the director of Rensselaerswyck, established Beverwyck as an independent village. When Fort Orange was surrendered to the English (Sept. 24, 1664) Beverwyck was named Albany, one of the titles of the duke of York (afterward James II.). In 1673-74 Albany again came under Dutch control for about a year, during which time it was called Willemstadt. Meanwhile the van Rensselaer family in Holland was trying to obtain from the duke of York a patent for the colony which would restore to them the ownership of the former village of Beverwyck. The application came finally to Governor Dongan, who declined to grant it because he "did not think it convenient that the second town in the government should be in the hands of private men." The van Rensselaers thereupon relinquished their claims to Albany, and received a patent (1685) which erected the colony of Rensselaerswyck into an English manor. On July 22 1686, Governor Dongan granted to Albany a city charter, by which all vacant and unappropriated lands within its limits were vested in the mayor, aldermen, and commonalty of the city, thus ending the jurisdictional disputes. The first mayor, appointed by the governor, was Peter Schuyler (1657-1724). In 1643, according to Father Jogues, the settlement consisted of 25 or 30 houses, built along the river; in 1695 the Rev. John Miller found 200 houses; at the first federal census (1790) the population was 3,498; by 1850 it had reached 50,763, and in 1910, 100,253. As late as 1750 a Swedish naturalist, Peter Kahn, who wrote a vivid description of the city, found the language and manners still Dutch, though the dress was in English style. Albany became the permanent state capital in 1797.

Its strategic position at the gateway of the Iroquois country and at the head of navigation on the Hudson made Albany highly important throughout the colonial period. In 1689 the first inter-colonial convention was held here, when delegates from Massachusetts bay, Plymouth, Connecticut, and New York met to treat with representatives of the five nations and to plan a system of defence. The Albany Congress of 1754 was a similar and more important gathering, including commissioners also from New Hampshire, Rhode Island, Pennsylvania, and Maryland, which met in anticipation of renewed hostilities with the French. It secured from the Indians assurances of their continued support, and adopted a plan (proposed by Benjamin Franklin) for "one general government" of the English colonies for purposes of common defence. The "Albany plan," though disapproved both by the home Government and by the colonies, paved the way for the congress of 1765 and the Continental congress of 1774. During the Revolution the British looked upon Albany as "a capital object to be subdued," and it was the objective of Burgoyne's expedition which ended with the battle of Saratoga. In 1839 it became the centre of the "Anti-Rent War," which was precipitated by the death of the last patroon and the attempt of his heirs to collect overdue rents, and was not entirely settled until 1847.

The first newspaper, the *Gazette*, was founded in 1771. The *Argus*, founded in 1813, was long the organ of the coterie of New York politicians known as the "Albany regency," and was one of the most influential Democratic papers in the country. The *Evening Journal*, founded in 1830, and edited for 35 years by Thurlow Weed, was equally influential as an organ of the Whig, and later of the Republican party.

See J. Munsell, *The Annals of Albany* (Albany, 1850-59); E. B. O'Callaghan, *Documentary History of the State of New York*, vol. iii. (Albany, 1850); William Barnes, *The Settlement and Early History of Albany* (Albany, 1851); *Collections on the History of Albany* (1865-71); G. R. Howell and J. Tenney, *Bi-Centennial History of Albany* (1866); A. J. Weise, *History of the City of Albany* (Albany, 1884); Amasa J. Parker, *Landmarks of Albany County* (Syracuse, 1897); Cuyler Reynolds, *Albany Chronicles* (Albany, 1906); John Boyd Thatcher 2nd, and others, *Albany's Tercentenary* (Albany, 1924).

ALBANY, a city of Oregon, U.S.A., on the Willamette river, about 80 m. S. of Portland; the county seat of Linn county. It is on the Pacific highway, and is served by the Southern Pacific, and the Oregon Electric railways. The population was 4,840 in 1920 and about 5,325 in 1930.

Albany is an important railway centre. It manufactures chairs, boxes, garage doors, saddles and harness, condensed and powdered milk; and has a cannery, a flour mill, a meat-packing plant, a foundry and machine shop, a creamery, and a number of smaller industries. It is the seat of Albany college (established 1866), which guarantees to students an opportunity to earn part of their expenses. Albany was settled in 1846 and incorporated as a city in 1865.

ALBANY, a river of Canada, rises in Lake St. Joseph in 91° 25' W. and 50° 55' N., and flows east-north-east into James Bay; length, over 400m.; navigable for nearly half its length, to Martin's Falls. There are four Hudson Bay Company's posts on its banks, including Fort Albany at its mouth. The Ogoki and Kenogami rivers are the principal tributaries.

ALBANY CONGRESS, a gathering of delegates from several American colonies important for the plan which it devised for colonial union. In accordance with instructions from the British Board of Trade (Sept. 18, 1753), 25 delegates, representing the four New England colonies, New York, Pennsylvania and Maryland, met at Albany, N. Y., on June 19, 1754, for the express purpose of formulating a concerted Indian policy. It was early apparent to the delegates that the question of colonial union was of even greater importance than a common Indian policy, so a committee was appointed to prepare a plan. The plan reported was chiefly the work of Benjamin Franklin and was unanimously adopted. It provided for a president-general to be appointed by the Crown, and for a grand council to be elected by the colonial assemblies. This grand council was empowered to raise and pay soldiers, to build forts, and to equip vessels to guard the coasts. The necessary funds were to be raised by the grand council, which was to have power to levy taxes and impose general duties. In this grant of power is seen the first suggestion of the important Federal principle which underlies the entire Federal structure in the United States—the right of the General Government to operate directly upon individuals. The plan was too comprehensive to suit the various Colonial Governments, which either rejected or failed to ratify it. It was never formally presented to the British Government. As a result of this unfavourable action by the Colonial Governments the Albany congress failed to solve either the question of colonial union or of joint Indian policy.

See R. Frothingham, *Rise of the Republic of the U.S.* (1881); G. L. Beer, *British Colonial Policy, 1754-1765* (1907); E. B. Greene, *Foundations of American Nationality* (1922); J. T. Adams, *Revolutionary New England* (1923). (C. C. Ta.)

ALBANY REGENCY, the name given to a coterie of politicians who from about 1820 to 1854 largely controlled the machinery of the Democratic Party in the State of New York. The members of this group constituted the first highly effective American political machine. They derived their power chiefly from their great personal influence and political sagacity. On the whole they actively opposed political corruption, though they always acted on the principle, first stated in 1833 by one of their ablest leaders (Marcy), that "to the victors belong the spoils." Among the members of this unofficial body, whose headquarters were at Albany, were Martin Van Buren, W. L. Marcy, Silas Wright and John A. Dix. About 1848 the opponents of the group began to adopt similar tactics, soon dividing the Democratic Party into irreconcilable factions, and thereafter the prestige of the "regency" rapidly waned.

ALBATEGNIUS (MOHAMMED BEN GEBIR AL BATANI, commonly called ALBATEGNICES) (c. 850-929), an Arab prince and astronomer, was born at Batan in Mesopotamia. From his observations at Aracte and Damascus, where he died, he was able to correct some of Ptolemy's results, previously taken on trust. He compiled new tables of the sun and moon, long accepted as authoritative, discovered the movement of the sun's apogee, and assigned to annual precession the improved value of 55". Perhaps independently of Aryabhata (born at Pataliputra on the Ganges A.D. 476), he introduced the use of sines in calculation, and partially that of tangents. His principal work, *De Motu Stellarum*, was published at Nuremberg in 1537 by Melanchthon, in a blundering Latin translation by Plato Tiburtinus

(c. 1116), annotated by Regiomontanus. A reprint appeared at Bologna in 1645. The original manuscript is preserved at the Vatican; and the Escorial library possesses in manuscript a treatise of some value by him on astronomical chronology.

See Houzeau, *Bibliographie astronomique*, i. 467; M. Marie, *Histoire des sciences*, ii. 113; R. Wolf, *Geschichte der Astronomie*, p. 67; Delambre, *Hist. de l'astr. au moyen âge*, ch. ii.; *Phil. Trans.*, 1693 (913), where E. Halley supplies corrections to some of the observations recorded in *De Motu Stellarum*.

ALBATROSS. A sea bird of the family *Diomededidae*, related to the petrel. The large, strong beak ends in a hook. The webbed feet lack the hind toe. *Diomedea exulans* of the Pacific is the best known. It is the largest sea bird, attaining a length of 4 ft., a weight of 25 lb., and the unique wing-spread of 17 ft.; it is remarkable for its soaring flight. It feeds upon fish and offal, and when gorged may be unable to fly. Both sexes are white, streaked with dark bands on the back and with dark wings. The bird lays one white egg, 4 in. long, on the ground; it nests on Tristan da Cunha and similar islands. The joint courtship dance is remarkable. About 20 species are known. The black-footed albatross (*D. nigripes*) and short-tailed albatrosses (*D. albatrus*) are found in the north Pacific from California to Alaska. The yellow-nosed albatross and sooty albatross, of related species, are casual visitors as far north as the state of Oregon in the United States.

ALBAY, a municipality (with administrative center and 32 barrios or districts) and the capital of the province of Albay, Luzon, P.I., near an inlet on the west shore of the Gulf of Albay, about 200 m. by road S.E. of Manila. Pop. (1918) 52,756, of whom 25,992 were males and 115 whites of both sexes; literacy (based on ages from 10 years up, 1918) 62.9%. The district of Legaspi (merged with Albay in Oct. 1907) is the port for the municipality. Albay is one of the most important municipalities in the Philippines. It lies on level ground near the south base of Mount Mayon, 7,500 ft. high, and with the most perfect volcanic cone known, from which it is sheltered by the Linguin hills. Good motor roads connect it with all parts of the province and with Manila, and it has railway and steamboat connections with various places as well. It has no pronounced dry season but the climate is excellent. The surrounding country is one of the most important *abacá* (Manila hemp) producing regions in the archipelago. *Sinamay* and *pinolpog* (sinamay with its fibres flattened by beating) are woven extensively and much *abacá* is shipped to Manila. Copra, sugar, rice, corn, sweet-potatoes and tobacco are among the other products of the region. In 1918 there were 21 manufacturing establishments of all kinds with a capital of 162,400 pesos and a total product valued at 240,800 pesos. The language is Bicol. Formally created in 1636, Albay had a population in 1649 of about 1,200, a church, a fortified house and part of a wall. In February 1815, an exceptionally violent eruption of the volcano destroyed much of the site and of the nearby district, killing about 1,200 people; and the eruption of 1897 also did some damage. In 1900, Albay was partially destroyed by the insurgents, but in 1901 civil Government was established by the United States. Since then there has been considerable rebuilding under American direction and the municipality is steadily growing in importance. It has a high school and forty-three other schools of all kinds.

ALBEDO (from Lat. *albus*, white), "whiteness," a word used principally in astronomy for the measure of reflecting power. A body shining by reflected light is said to have albedo $\frac{1}{2}$ if it reflects (or scatters outwards) half the light incident on it. The albedo for visual light of the cloud-covered planets (Venus, Jupiter, Saturn, Uranus, Neptune) ranges from 0.56 to 0.73; of the earth 0.44; Mars 0.15; Moon 0.07. (See H. N. Russell, *Astrophysical Journal*, vol. xliii. p. 173.)

ALBEMARLE, WILLIAM DE FORS or **DE FOR-TIBUS**, EARL OF (d. 1242), was a great-grandson of King Stephen and a son-in-law of William of Blois. He is described by Bishop Stubbs as a "feudal adventurer of the worst type." He was one of the executors of Magna Carta, but frequently changed sides in the civil war that followed, his general aim being to revive the power of the feudal barons. In 1221, 1222 and 1223 he was

in revolt, although in each case he was compelled to submit, and was twice excommunicated. He died at sea on his way to the Holy Land on March 26, 1242.

ALBEMARLE, GEORGE MONK or MONCK, 1st duke of. *See* MONK.

ALBEMARLE, ARNOLD JOOST VAN KEPPEL, 1st earl of (1669–1718), was born in Holland, and accompanied William III. to England in 1688. He was created earl of Albemarle in 1697.

THORNTON ABBEY IN LINCOLNSHIRE, FOUNDED BY WILLIAM OF BLOIS AN ANCESTOR OF THE ALBEMARLE FAMILY

The confidant of the king, he returned to Holland at his death, and became a general of horse in the Dutch army. He joined the allied forces in 1703, fought at Ramillies, Oudenarde, and the siege of Lille. He led Marlborough's second line in 1711.

ALBEMARLE, GEORGE THOMAS KEPPEL, 6th earl of (1799–1891), British general, served in the campaign of Waterloo. He was aide-de-camp to the marquess of Hastings in India, returning home in 1823 by way of Persia and St. Petersburg (now Leningrad). He wrote a narrative of the journey, *Journey from India to England* (1825). Gen. Keppel sat in the first reformed parliament as a member for East Norfolk (1832–35) and for Lymington (1847–49). He succeeded to the title in 1851.

See his *Fifty Years of My Life* (1875).

ALBEMARLE AND CHESAPEAKE CANAL, in the United States, connecting Norfolk, Va., with Currituck Sound, N.C., is a portion of the inland navigation between New York, Philadelphia, Baltimore and North Carolina and is connected with the Chesapeake and Delaware and Raritan canals. It is 11.2m. long, 80ft. wide, 12ft. in depth and has one lock. Its capacity is steamers of approximately 800 tons, drawing 11ft. of water. The canal was opened in 1860, and the cost of construction was \$1,641,363.

ALBEMARLE SOUND, a large inlet on the Atlantic coast of North Carolina, U.S.A. It has an east and west direction extending along the 36th parallel of north latitude, a length of about 50m., and a breadth of from 5 to 15 miles. The depth varies from a few feet to 20ft. or more. Albemarle is separated from the Atlantic by a long narrow barrier beach. From the north-east end of the Albemarle the long, narrow arm called Currituck sound extends northward about 40m. to and beyond the Virginia border. On the south-east Albemarle is connected with Pamlico sound by Croatan sound, and also by a narrower channel, Roanoke sound, separated from the former by Roanoke Island. From Albemarle sound project many bay-like arms, commonly called rivers, because they serve as the mouths of streams; but they are true bays, having a breadth of several miles and a depth about equal to that of the sound. Roanoke river (*q.v.*) is the most important stream emptying into it. Albemarle is connected with Norfolk, Va., harbour partly by natural and partly by artificial waterways (Dismal Swamp canal and the Albemarle and Chesapeake canal), thus forming an important link in the great inland waterway extending from Massachusetts to Beaufort, North Carolina.

ALBENGA, town and episcopal see, province of Liguria, Italy, on the north-west coast of the Gulf of Genoa, 52½m. S.W.

of Genoa by rail. Pop. (1921), 4,578 (town), 7,557 (commune). Albenga is the ancient *Album Ingaunum* or *Albingaunum*, the chief town of the Ingauni, whose territory reached as far as Genoa. An inscription records the restoration of the walls, forum, harbour, etc., by Constantius A.D. 354. To the east is a well-preserved Roman bridge, Ponte Lungo, nearly 500ft. long and 11½ft. wide, with 10 arches, each with a span of 37ft. To the south is a conspicuous rectangular pillar, 27ft. high, probably marking a tomb. A good brick Gothic cathedral has an interesting octagonal baptistery (8th or 9th century).

ALBENIZ, ISAAC (1860–1909), Spanish pianist and prolific composer, who only towards the close of his career found his true métier and wrote the works which give him his chief claim to remembrance. These were his brilliant and fascinating piano-forte pieces, such as the suite *Iberia*, reproducing the rhythms and other characteristic features of Spanish popular music. He wrote also a number of works for the stage, including a comic opera, *The Magic Opal*, produced in London, and a more ambitious work, *Pepita Jiménez*, but these were of less account.

ALBERONI, GIULIO (1664–1752), Spanish-Italian cardinal and statesman, the son of a gardener, born near Piacenza, probably at the village of Fiorenzuola. He took priest's orders, and found his way to Rome in attendance on the son of a bishop. During the War of the Spanish Succession Alberoni rendered substantial services to the Duke of Vendôme, commander of the French forces in Italy, and in 1711 he followed him into Spain as his secretary. Two years later Alberoni was appointed consular agent for Parma at the court of Philip V. of Spain, and helped to arrange the king's marriage with Elizabeth Farnese of Parma, by whose influence he was made a member of the king's council, bishop of Malaga, and in 1715 prime minister. Alberoni's foreign policy was to undo the work of the Treaty of Utrecht. He desired to gain the succession of Elizabeth to Parma and Piacenza, then in the hands of Austria. To this end he made hurried attempts to reform the administration and the military and financial organization of Spain. But the impatience of Elizabeth left him no time to mature his plans. In 1718 Alberoni equipped a small expedition to help the Scottish Jacobites against George II., but the fleet was wrecked on its way from Cadiz. The Spanish ambitions in Italy led to the Quadruple Alliance of England, France, Austria and Holland, all of which needed a long period of peace for recovery from the last war, and after the landing in 1718 of Spanish troops at Palermo, French armies and English ships invaded Spain. After the Spanish collapse Alberoni was exiled, and went to Italy, where he took refuge in the Apennines, Pope Clement XI., who was his bitter enemy, having ordered his arrest. On the latter's death Alberoni appeared at the Conclave and took part in the election of Innocent XIII. (1721), after which he was imprisoned for a time by the Pope, at Spain's demand. At the next election, he was himself proposed for the papal chair, and secured 10 votes at the Conclave which elected Benedict XIII. He died on June 16, 1752. Alberoni left a number of manuscripts, but the genuineness of the *Political Testament* published under his name at Lausanne in 1753 has been questioned.

An *Histoire du Cardinal Alberoni* up to 1719 was published by Jean Rousset de Missy at The Hague in 1719. A laudatory life, *Storia del Cardinale Giulio Alberoni*, was published by Stefano Bersani, a priest educated at his college, at Piacenza, in 1861. *Giulio Alberoni e il suo secolo*, by Giovanni Bianchi (1901), is briefer and more critical. *See* also *Lettres intimes de J. Alberoni*, edited by M. E. Bourgeois (1892).

ALBERT I. (1875–), king of the Belgians, was born at Brussels, April 8, 1875, the younger son of Philip, count of Flanders (1837–1905), who was a brother of Leopold II., and Princess Marie of Hohenzollern. The other children of this marriage were Baldwin (b. 1869), Henriette, afterwards duchess of Vendôme (b. 1870), a daughter who died in infancy, and Josephine, afterwards Princess Charles of Hohenzollern (b. 1872).

The premature death of Prince Leopold, only son of Leopold II., on June 22, 1869, made Prince Baldwin heir presumptive to the Belgian crown, but on his death on Jan. 23, 1891, Prince Albert

became next in the line of succession. He was carefully educated, and showed a marked taste for engineering and mechanics, studying both naval and aerial construction. He received his training in military matters at the École Militaire under Gen. Jungblut, and also became a thorough sportsman, taking much interest in mountaineering and later in aviation. He served as an officer in the Grenadier regiment. On Oct. 2, 1900 he was married at Munich to Elisabeth (b. July 25, 1876), second daughter of Duke Charles Theodore of Bavaria. Three children were born of this marriage: Leopold, duke of Brabant (b. Nov. 3, 1901); Charles, count of Flanders (b. Oct. 10, 1903) and Marie José (b. Aug. 4, 1906).

Prince Albert also travelled widely, paying a visit to America in 1898, and in 1903 visiting England in order to study naval construction. In April 1909 he went to the Belgian Congo. Starting from the Cape, he visited the Cape province and the Transvaal, going from there to Elisabethville. Thence he traversed the Katanga mineral region and followed the course of the Congo to its mouth. He returned to Belgium in August, and three months later King Leopold died.

On Dec. 1, 1909 Prince Albert took the oath of fidelity to the Belgian constitution, and became king under the name of Albert I. In his speech from the throne, the king emphasized his care for the people's welfare in the words: "Our prosperity depends upon the prosperity of the masses." He occupied himself more especially with the organization of the army, and in May 1913 gave his assent to the law which was designed to secure for Belgium an army of 350,000 men. He also interested himself in various social and legal reforms, while his scientific tastes did not prevent him becoming a friend of art and literature. The economist Waxweiler, the poet Verhaeren and the painter Laermans were on friendly terms with the royal family, the latter receiving personal attention from the queen when he was threatened with the loss of his sight.

Albert was anxious to preserve friendly relations with neighbouring States, and after 1910 paid official visits both to Berlin and Paris. On Nov. 5 and 6, 1913, the king, who had been appointed honorary colonel of the regiment of Hanover Dragoons, visited Germany for the second time. At a reception in Potsdam, the Emperor William II. and Gen. von Moltke informed him that they considered war with France imminent. The king gave warning of this to the French ambassador in Berlin through his own minister plenipotentiary, Baron Beyens. On July 31, 1914, when the European crisis came to a head, the king wrote a personal letter to the German emperor, reminding him of the respect due to Belgian neutrality. Germany replied by the ultimatum of Aug. 2, which in turn was answered by a *fin de non recevoir* and hostilities began. The king took command of the troops and established his headquarters first at Louvain and afterwards at Antwerp. He directed in person the first advance from Antwerp towards Louvain, which was intended to relieve the French and British armies engaged with the forces of Kluck and Bülow. After the fall of Antwerp, the king and queen sent their children to England, while they themselves accompanied the retreating army; when it came to a halt on the Yser they took up their residence at Furnes. From Oct. 17 to 24 the Belgian army, under the king's command, withstood the German invasion without any Allied assistance. During the whole of the war he remained with the troops, having his headquarters at La Panne, where he was exposed to the risk of enemy bombardments. He made continual visits to the front-line trenches, and even surveyed the enemy's lines from an aeroplane. The queen remained with him, acting as a nurse in the Hôpital de l'Océan at La Panne. She also interested herself deeply in the welfare of the soldiers in the trenches, and superintended the establishment of canteens and aid posts. Prince Leopold, King Albert's elder son, lived by his father's wish, the life of a simple soldier in the 12th Regiment.

When the general offensive of Oct. 1918 was undertaken, Albert was appointed commander of the northern army groups, consisting of both Belgians and French, which captured the forest of Houthulst, "the Flandernstellung," Thourout, Ostend and Bruges, and forced the passage of the Lys. On Nov. 11, 1918 the king

and queen made their entry into Ghent, and on Nov. 22 into Brussels, being received with enormous enthusiasm. Even before the signing of the Armistice the king had summoned at Lophem a number of politicians and had arranged a new government containing representatives of the three more important Belgian political parties. After a triumphant reception by parliament, the king made a speech from the throne, in which he urged that all parties should work together for national reconstruction, while, addressing himself to the Allies, he asked for the abolition of Belgian neutrality and of the treaties of 1839 which had left Belgium open to invasion. After the Armistice, King Albert declined the augmentation of his civil list. He occupied himself actively with the improvement of conditions in his country, visiting the devastated areas, and contributing considerable sums to "King Albert's Fund," which was devoted to providing temporary shelter for sufferers from the war.

The king in person presided at the Colonial Congresses of 1920 and 1926 and made important speeches on those occasions. He was actively interested in the development of the Belgian mercantile marine. As before the war, he continued to support the intellectual development of his country. After the war he made official visits to the State universities of Ghent and Liège. In Jan. 1926 King Albert, who had been given honorary degrees by many universities, was elected a member of the *Institut de France*. His solicitude for the welfare of his people was unfailing and, during the floods which ravaged Belgium in Dec. 1925, he and his queen lost no time in succouring the distressed inhabitants of the inundated districts. (See BELGIUM.)

ALBERT I. (c. 1250–1308), German king and duke of Austria, eldest son of King Rudolph I., was invested with the duchies of Austria and Styria in 1282. On Rudolph's death in 1291 Albert was obliged to acquiesce in the election of Adolf of Nassau as German king, but in 1298 he mustered sufficient allies to enable him to defeat Adolf at Göllheim, near Worms, was elected king at Frankfurt on July 27, and crowned at Aix on Aug. 24. Pope Boniface VIII. declined to recognize him until 1303 when Albert admitted the right of the pope to bestow the imperial crown and promised that none of his sons should be elected king without papal consent. In 1306 he secured the crown of Bohemia for his son Rudolph, but tried in vain to impose his own claims on Thuringia in 1307. His action in abolishing all tolls established on the Rhine since 1250, led to the formation of a league against him by the Rhenish archbishops and the count palatine of the Rhine; but aided by the towns, he soon crushed the rising. He was on the way to suppress a revolt in Suabia when he was murdered on May 1, 1308, at Windisch on the Reuss, by his nephew John, afterwards called the "Parricide," whom he had deprived of his inheritance.

Although a hard, stern man, he had a keen sense of justice when his selfish interests were not involved, and few of the German kings possessed so practical an intelligence. He encouraged the cities, and not content with issuing proclamations against private war, formed alliances with the princes in order to enforce his decrees. The serfs, whose wrongs seldom attracted notice in an age indifferent to the claims of common humanity, found a friend in this severe monarch, and he protected even the despised and persecuted Jews. The stories of his cruelty and oppression in the Swiss cantons first appear in the 16th century, and are now regarded as legendary.

See A. L. J. Michelsen, *Die Landgrafschaft Thüringen unter den Königen Adolf, Albrecht, und Heinrich VII.* (Jena, 1860); G. Droysen, *Albrechts I. Bemühungen um die Nachfolge im Reich* (Leipzig, 1862); J. F. A. Mücke, *Albrecht I. von Habsburg* (Gotha, 1866).

ALBERT II. (1397–1439), German king, king of Bohemia and Hungary, and (as Albert V.) duke of Austria, was born on Aug. 10, 1397, the son of Albert IV. of Habsburg, duke of Austria.

He succeeded to the duchy of Austria on his father's death in 1404, and in 1438 succeeded his father-in-law, Sigismund, as German king, though he does not appear to have sought election.

He was crowned king of Hungary and of Bohemia but was unable to obtain possession of the latter country. His reign, which lasted less than two years, was spent in the defence of Hungary against the Turks. He died at Langendorf on Oct. 27, 1439. Albert was an energetic and warlike prince, whose short reign gave great promise of usefulness for Germany.

See W. Altmann, *Die Wahl Albrecht II. zum römischen Könige* (1886).

ALBERT, FREDERICK AUGUSTUS (1828–1902), king of Saxony, was born April 23, 1828, being the eldest son of Prince John, who succeeded to the throne in 1854. In 1849 he served as a captain in the campaign of Schleswig-Holstein against the Danes. When the war of 1866 broke out, the crown prince was placed in command of the Saxon forces opposing the Prussian army of Prince Frederick Charles. No attempt was made to defend Saxony; the Saxons fell back into Bohemia and effected a junction with the Austrians. They took a prominent part in the battles by which the Prussians forced the line of the Iser and in the battle of Gitchin. The crown prince, however, succeeded in effecting the retreat in good order, and in the decisive battle of Koeniggratz (*see* SEVEN WEEKS' WAR) he held the extreme left of the Austrian position with great tenacity. After peace was made and Saxony had entered the North German confederation, he was placed in command of the Saxon army, which had now become the XII. Army Corps of the North German army. He was a firm adherent of the Prussian alliance.

On the outbreak of war in 1870 he again commanded the Saxons, who formed the extreme left of the German army, at Gravelotte, and with the Prussian Guard carried out the attack on St. Privat, the final and decisive action in the battle. In the march towards Paris the crown prince was given a separate command over the 4th army (army of the Meuse) consisting of the Saxons, the Prussian Guard corps, and the 4th (Prussian Saxony) corps. He took a leading part in the operations which preceded the battle of Sedan, the 4th army being the pivot on which the whole army wheeled round in pursuit of MacMahon; and the actions of Buzancy and Beaumont on Aug. 29 and 30 were fought under his direction; in the battle of Sedan itself, with the troops under his orders, he carried out the envelopment of the French on the east and north. Albert had won the complete confidence of the army, and during the siege of Paris his troops formed the north-east section of the investing force. After the armistice he was left in command of the German army of occupation, a position which he held till the fall of the Commune.

On the conclusion of peace he was made an inspector-general of the army and field-marshal. On the death of his father on Oct. 29, 1873, he succeeded to the throne. The king devoted himself mainly to military affairs, in which his advice and experience were of the greatest value to the German army in general. In 1897 he was appointed arbitrator between the claimants for the principality of Lippe. King Albert married in 1853 Carola, daughter of Prince Gustavus of Vasa, and granddaughter of the last king of Sweden of the house of Holstein. He died June 10, 1902.

ALBERT (1522–1557), prince of Bayreuth, surnamed **THE WARLIKE**, and also **ALCIBIADES**, was a member of the Franconian branch of the Hohenzollern family. His restless and turbulent nature marked him out for a military career; and having collected a small band of soldiers, he assisted the emperor Charles V. in his war with France in 1543. Sharing in the attack on the Saxon electorate, Albert was taken prisoner at Rochlitz in March 1547 by John Frederick, elector of Saxony, but was released as a result of the emperor's victory at Mühlberg in the succeeding April. He then followed the fortunes of his friend Maurice, the new elector of Saxony, deserted Charles, and joined the league which proposed to overthrow the emperor by an alliance with Henry II. of France. Having extorted a large sum of money from the burghers of Nuremberg, he quarrelled with his supporter, the French king, and offered his services to the emperor. Charles,

anxious to secure such a famous fighter, gladly assented to Albert's demands and gave the imperial sanction to his possession of the lands taken from the bishops of Würzburg and Bamberg. After Albert had been placed under the imperial ban in Dec. 1553 on account of his depredations in Franconia, he was defeated by Henry II., duke of Brunswick, and compelled to fly to France. He there entered the service of Henry II., and had undertaken a campaign to regain his lands when he died at Pforzheim Jan. 8, 1557.

See J. Voigt, *Markgraf Albrecht Alcibiades von Brandenburg-Kulmbach* (Berlin, 1852).

ALBERT, PRINCE CONSORT OF ENGLAND (1819–1861), b. at Rosenau Aug. 26, 1819. Francis Charles Augustus Albert Emmanuel was the second son of the hereditary duke of Saxe-Coburg-Gotha (belonging to the Ernestine or elder branch of the royal family of Saxony) by his first wife, the Princess Louise of Saxe-Gotha-Altenburg (d. 1831), from whom the duke was separated in 1824. His father's sister married the duke of Kent, and her daughter, afterwards Queen Victoria of England, was thus his first cousin. They were born in the same year. Albert and his elder brother, Ernest, were educated privately and at the University of Bonn. There Prince Albert studied natural science, political economy, and philosophy; he diligently cultivated music and painting, and excelled in gymnastic exercises, especially in fencing.

The idea of a marriage between him and his cousin Victoria had always been cherished by their uncle, King Leopold I. of Belgium, and in May 1836 the duke of Saxe-Coburg-Gotha and his two sons paid a visit to the duchess of Kent and her daughter at Kensington Palace. The visit was by no means to the taste of King William IV., who disapproved of the match and favoured Prince Alexander of Orange. But Leopold's plan was known to Princess Victoria, and William's objections were fruitless. Princess Victoria, writing to her uncle Leopold (May 23, 1836) said that Albert was "extremely handsome," and (June 7) thanked him for the "prospect of great happiness you have contributed to give me in the person of dear Albert. He possesses every quality that could be desired to render me perfectly happy." In the winter of 1838–39 the prince travelled in Italy, accompanied by Baron Stockmar, the Queen's confidential adviser, formerly Leopold's doctor and private secretary. On Oct. 10, 1839, he and Ernest went again to England to visit the Queen, with the object of finally settling the marriage. The betrothal took place on Oct. 15, and on Feb. 10, 1840 the marriage was celebrated at the chapel-royal, St. James's.

The public life of the Prince Consort cannot be separated from that of the Queen, and it is unnecessary here to repeat such details as are given in the article (*see* VICTORIA, ALEXANDRINA). The prejudice against him, on account of what was regarded as his undue influence in politics, was never fully dissipated till after his death. His co-operation with the Queen in dealing with the political responsibilities which devolved upon the sovereign represented an amount of conscientious and self-sacrificing labour which cannot easily be exaggerated; and his wisdom in council could only be realized, outside a very small circle, when in later years the materials for the history of that time became accessible. He was indeed a man of cultured and liberal ideas, well qualified to take the lead in many reforms which the England of that day sorely needed. He was specially interested in endeavours to secure the more perfect application of science and art to manufacturing industry.

The Great Exhibition of 1851 originated in a suggestion he made at a meeting of the Society of Arts, and owed the greater part of its success to his intelligent and unwearied efforts. He had to work for its realization against an extraordinary outburst of angry expostulations. Every stage in his project was combated. In the House of Peers, Lord Brougham denied the right of the Crown to hold the exhibition in Hyde Park; in the Commons, Colonel Sibthorp prophesied that England would be overrun with foreign rogues and revolutionists, who would subvert the morals of the people, filch their trade secrets from them, and destroy their faith and loyalty towards their religion and their sovereign.

Prince Albert was president of the exhibition commission, and every post brought him abusive letters, accusing him, as a foreigner, of being intent upon the corruption of England. He was not the man to be balked by talk of this kind, but quietly persevered, looking always to the probability that the manufacturing power of Great Britain would be quickened by bringing the best manufactured products of foreign countries under the eyes of the mechanics and artisans. The exhibition was opened by the Queen on May 1, 1851, and was a colossal success; and the realized surplus of £150,000 went to establish and endow the South Kensington Museum (afterwards renamed "Victoria and Albert") and to purchase land in that neighbourhood.

THE ALBERT MEMORIAL IN LONDON, BEGUN IN 1872 AND COMPLETED IN 1876. ERECTED IN MEMORY OF ALBERT, PRINCE CONSORT OF ENGLAND

Similar institutions, on a smaller scale but with a kindred aim, always found in him warm advocacy and substantial support. It was chiefly at meetings in connection with these that he found occasion for the delivery of addresses characterized by profound thought and comprehensiveness of view, a collection of which was published in 1857. One of his best speeches is the inaugural address which he delivered as president of the British Association for the Advancement of Science when it met at Aberdeen in 1859. The education of his family and the management of his domestic affairs furnished the Prince with another very important sphere of action, in which he employed himself with conscientious devotion.

As the Prince became better known, public mistrust began to give way. In 1847, but only after a significantly keen contest with Earl Powis, he was elected chancellor of Cambridge University; and he was soon afterwards appointed master of Trinity House. In June 1857 the formal title of Prince Consort was conferred upon him by letters patent, in order to settle certain difficulties as to precedence that had been raised at foreign courts.

But in the full career of his usefulness he was cut off. During the autumn of 1861 he was busy with the arrangements for the projected international exhibition, and it was just after returning from one of the meetings in connection with it that he was seized with his last illness. Beginning at the end of November with what appeared to be influenza, it proved to be an attack of typhoid fever, and, congestion of the lungs supervening, he died on Dec. 14. The grief of the Queen was overwhelming and the sympathy of the whole nation marked a revulsion of feeling about the Prince himself which was not devoid of compunction for earlier want of appreciation. The magnificent mausoleum at Frogmore, in which his remains were finally deposited, was erected at the expense of the Queen and the Royal Family; and many public monuments to "Albert the Good" were erected all over the country, the most notable being the Albert Hall (1867) and the Albert Memorial (1876) in London. His name was also commemorated in the Queen's institution of the Albert medal (1866) in reward for gallantry in saving life, and of the order of Victoria and Albert (1862).

BIBLIOGRAPHY.—By the Queen's authority, her secretary, General Grey, compiled *The Early Days of the Prince Consort*, published in 1867; and *The Life and Letters of the Prince Consort* (1st vol., 1874; 2nd, 1880) was similarly edited by Sir Theodore Martin. A volume of the *Principal Speeches and Addresses of Prince Albert*, with an introduction by Sir Arthur Helps, was published in 1862. See also C. F. von Stockmar, *Memoirs* (1872); the *Letters of Queen Victoria* (1907); and Lytton Strachey, *Queen Victoria* (1921). (H. C.)

ALBERT (1490–1568), last grand master of the Teutonic Order, and first duke of Prussia, was born at Ansbach, May 16, 1490, the third son of Frederick of Hohenzollern, prince of Ansbach and Bayreuth, and Sophia, daughter of Casimir IV., king of Poland. In 1511 Albert was made grand master of the Teutonic Order, which had held East Prussia under Polish suzerainty since 1466. In 1519 Albert was at war with his Polish suzerain, and

though a truce was made in 1521 the dispute, which was referred to the emperor, remained unsettled. Albert was then converted to Protestantism, and, supported by the advice of Martin Luther, determined to make Prussia a hereditary duchy, though he was at the same time assuring Pope Adrian VI. that he intended to reform the Order and repress Lutheranism among the knights. Eventually in 1525 a treaty was signed at Cracow by Sigismund I. of Poland, agreeing to the creation of a duchy, provided it were held as a Polish fief, and Albert was formally invested on Feb. 10.

The new duke proceeded to further Protestantism in East Prussia. He was deposed from the grand mastership, but the Teutonic knights were unable to recover Prussia, and, although he was placed under the ban of the empire, it was never enforced. In imperial politics Albert was fairly active. Joining the league of Torgau in 1526, he acted in unison with the Protestants, and was among the princes who banded themselves together to overthrow Charles V. after the issue of the *Interim* in May 1548. The early years of Albert's rule in Prussia were fairly prosperous. Although he had some trouble with the peasantry, the lands and treasures of the church enabled him to propitiate the nobles and for a time to provide for the expenses of the court. He did something for the furtherance of learning by establishing schools in every town and by giving privileges to serfs who adopted a scholastic life. In 1544, in spite of some opposition, he founded a university at Königsberg, where he appointed his friend Osiander to a professorship in 1549. But Osiander's divergence from Luther's doctrine of justification by faith involved him in a violent quarrel with Melancthon, who had adherents in Königsberg, and these theological disputes soon created an uproar in the town. The duke strenuously supported Osiander, and the area of the quarrel soon broadened. After Osiander's death in 1552, a preacher named John Funck, with an adventurer named Paul Scalich, exercised great influence over him. The state of turmoil caused by these religious and political disputes compelled the duke to consent to a condemnation of the teaching of Osiander, and in 1566 the estates appealed to Sigismund II., king of Poland, who sent a commission to Königsberg. Scalich saved his life by flight, but Funck was executed; the question of the regency was settled; and a strict form of Lutheranism was declared binding on all teachers and preachers. The duke, a disappointed man, lived for two years longer, and died at Tapiau on March 20, 1568.

See J. Voigt, *Briefwechsel der berühmtesten Gelehrten des Zeitalters der Reformation mit Herzog Albrecht von Preussen* (Königsberg, 1841); K. Lohmeyer, *Herzog Albrecht von Preussen* (Danzig, 1890); E. Joachim, *Die Politik des letzten Hochmeisters in Preussen, Albrecht von Brandenburg* (Leipzig, 1892).

ALBERT III. (1443–1500), duke of Saxony, surnamed ANIMOSUS or THE COURAGEOUS, younger son of Frederick II., the Mild, elector and duke of Saxony, was born Jan. 27, 1443, and, after escaping from the hands of Kunz von Kaufungen, who had abducted him and his brother Ernest, passed some time at the court of the Emperor Frederick III. in Vienna. After the death of the Elector Frederick in 1464, Albert and Ernest ruled their lands together, but in 1485 a division was made by the Treaty of Leipzig, and Albert received Meissen, together with some adjoining districts, and founded the Albertine branch of the family of Wettin.

In 1475, Albert took a prominent part in the imperial campaign against Charles the Bold, duke of Burgundy, and in 1487 led an expedition against Matthias Corvinus, king of Hungary, which failed owing to lack of support on the part of the emperor. In 1488 he marched with the imperial forces to free the Roman king Maximilian from his imprisonment at Bruges, and after the king returned to Germany in 1489, Albert restored the authority of Maximilian in Holland, Flanders and Brabant. In 1498 Maximilian bestowed upon him the title of hereditary governor (potestat) of Friesland, but he had to make good his claim by force of arms. He was engaged in repressing a rising in Friesland when he died at Emden, Sept. 12, 1500. Albert, who was a man of great strength and considerable skill in feats of arms, delighted in tournaments and knightly exercises. His rule was a period of prosperity in Saxony in spite of the large sums which he spent campaigning in the emperor's service.

See F. A. von Langenn, *Herzog Albrecht der Beherzte, Stammvater des königlichen Hauses Sachsen* (Leipzig, 1838); O. Sperling, *Herzog Albrecht der Beherzte von Sachsen als Gubernator Frieslands* (Leipzig, 1892).

ALBERT, DUKE OF WÜRTTEMBERG (1865–), German general, the son of Duke Philip of Württemberg, was born in Vienna on Dec. 23, 1865. As the king and queen of Württemberg had no male heir, he was the heir presumptive to the Württemberg throne. He passed through the different grades of a military career and was appointed general in command of the XI. Army Corps at Cassel in 1906, and in 1908 was entrusted with the command of the Württemberg Army Corps. In 1913 he was advanced to the rank of generaloberst (colonel-general, immediately below field-marshal) and was appointed inspector-general of the VI. Army inspection. At the outbreak of the World War he took over the leadership of the IV. Army on the western front, was advanced to the rank of field-marshal-general in 1916 and appointed chief-in-command of the group of armies on the front in Alsace-Lorraine, which fought under his leadership until the end of the war. Since then he has lived as a private citizen on his Württemberg estates. He married in 1893 the late Archduchess Margarete Sophie of Austria (d. 1902), the sister of the Archduke Francis Ferdinand, who was assassinated at Sarajevo.

ALBERT I. (c. 1100–1170), margrave of Brandenburg, surnamed "the Bear," was the only son of Otto the Rich, count of Ballenstädt, and Eilika, daughter of Magnus Billung, duke of Saxony. He inherited the valuable Saxon estates of his father in 1123, and on his mother's death in 1142 succeeded to one-half of the lands of the Billungs. About 1123 he received from Lothair, duke of Saxony, the margraviate of Lusatia. In 1128 his brother-in-law, Henry II., margrave of the Saxon north mark, died, and Albert, disappointed at not receiving this fief, attacked Udo, the succeeding margrave, and was consequently deprived of Lusatia by Lothair. His services in Italy in 1132 were rewarded in 1134 by the investiture of the north mark, which was again without a ruler. For three years he was occupied in campaigns against the Wends, and by an arrangement made with Pribislaus, duke of Brandenburg, Albert secured this district when the duke died in 1150.

Taking the title margrave of Brandenburg, he pressed the warfare against the Wends, extended the area of his mark, did much for the spread of Christianity and civilization therein, and so became the founder of the margraviate of Brandenburg. In 1137 his cousin, Henry the Proud, had been deprived by King Conrad III. of his Saxon duchy, which was given to Albert. But he was driven from Saxony and also from his mark by Henry, and compelled to take refuge in South Germany, and when peace was made in 1142 he renounced the Saxon dukedom and received the counties of Weimar and Orlamünde.

It was possibly at this time that Albert was made arch-chamberlain of the empire, an office which afterwards gave the margraves of Brandenburg the rights of an elector. In 1162 Albert accompanied the Emperor Frederick I. to Italy, and distinguished himself at the storming of Milan. In 1164 he joined a league of princes formed against Henry the Lion, and peace being made in 1169, Albert divided his territories among his six sons. He died Nov. 13, 1170, and was buried at Ballenstädt. His personal qualities won for him the surname of "the Bear," and he is also called by later writers "the Handsome."

See L. von Heinemann, *Albrecht der Bär* (Darmstadt, 1864).

ALBERT III. (1414–86), elector of Brandenburg, surnamed *ACHILLES* because of his relentless energy and physical strength, and his combination of shrewdness and knight-errantry, was the third son of Frederick I. of Hohenzollern, elector of Brandenburg. Albert was born at Tangermünde on Nov. 9, 1414, and died at Frankfurt on March 11, 1486. On the division of territory which followed his father's death in 1440 he received the principality of Ansbach; on the death of his brother John in 1464 he inherited Bayreuth; and in 1470, on the abdication of his brother Frederick II., he became elector of Brandenburg. His main object was family aggrandizement, and he became as powerful among the northern as the elector of the Palatinate

among the southern princes. He saw that division of inheritance weakened the family power, and he devised the famous *Dispositio Achillea* of 1473, which decreed that the mark of Brandenburg should descend intact to the eldest son, the younger son receiving the Franconian possessions of the Hohenzollerns. Both sections of the family lands were to descend thenceforward by primogeniture, a new principle in the succession of the German princely houses. He married his daughter Barbara to Henry VI. of Glogau, and after her husband's death secured a part of his Pomeranian lands for his daughter in 1482. The power of Brandenburg declined with his death. It is said that the old warrior, who had spent the greater part of his life either in fighting against the towns which desired to maintain their independence, or the princes who sought reforms, or in purely dynastic struggles, realized at the end of his life that military strength was useless so long as Germany had no sound peace, no good system of law and no general currency.

See *Das kaiserliche Buch des Markgrafen Albrecht Achilles, Vorkurfürstliche Periode, 1440–70*, ed. by C. Hoefler (Bayreuth, 1850); *Kurfürstliche Periode*, ed. by J. von Minutoli (1850); *Quellensammlung zur Geschichte des Hauses Hohenzollern*, Band I., ed. by C. A. H. Burkhardt (Jena, 1857); O. Franklin, *Albrecht Achilles und die Nuremberger, 1449–53* (1866); *Politische Korrespondenz des Kurfürsten Albrecht Achilles, 1470–86*, ed. by F. Priebatsch (Leipzig, 1894–98); J. G. Droysen, *Geschichte der preussischen Politik* (1855–86).

ALBERT (1490–1545), elector and archbishop of Mainz, and archbishop of Magdeburg, was the younger son of John Cicero, elector of Brandenburg, and was born June 28, 1490, and died at Aschaffenburg Sept. 24, 1545. In 1513 he became archbishop of Magdeburg and administrator of the diocese of Halberstadt. In 1514 he obtained the electorate of Mainz, and in 1518 was made a cardinal.

Meanwhile to pay for the pallium of the see of Mainz and to discharge the other expenses of his elevation, Albert had borrowed a large sum of money from the Fuggers, and had obtained permission from Pope Leo X. to conduct the sale of indulgences in his diocese to obtain funds to repay this loan. For this work he procured the services of John Tetzel, and so indirectly exercised a potent influence on the course of the Reformation. When the imperial election of 1519 drew near, the elector's vote was eagerly solicited both by the partisans of Charles (afterwards the Emperor Charles V.) and of Francis I., king of France, and he appears to have received a large amount of money for the vote which he cast eventually for Charles. Albert's large and liberal ideas, his friendship with Ulrich von Hutten, and his political ambitions, appear to have raised hopes that he would be won over to the reformed faith; but after the peasants' war of 1525 he ranged himself definitely among the supporters of Catholicism. He was nevertheless compelled to grant religious liberty to the inhabitants of Magdeburg in return for 500,000 florins.

During his latter years indeed he showed more intolerance towards the Protestants. Albert adorned the *Stiftskirche* at Halle and the cathedral at Mainz in sumptuous fashion, and took as his motto the words *Domine, dilexi decorum domus tue*. A generous patron of art and learning, he counted Erasmus among his friends.

See J. H. Hennes, *Albrecht von Brandenburg, Erzbischof von Mainz und Magdeburg* (Mainz, 1858); J. May, *Der Kurfürst, Kardinal, und Erzbischof Albrecht II. von Mainz und Magdeburg* (Munich, 1865–75); W. Schum, *Kardinal Albrecht von Mainz und die Erfurten Kirchenreformation* (Halle, 1878); P. Redlich, *Kardinal Albrecht von Brandenburg, und das neue Stift zu Halle* (Mainz, 1900).

ALBERT (FRIEDRICH RUDOLF ALBRECHT), ARCHDUKE (1817–1895), Austrian field-marshal, the eldest son of the Archduke Charles (Karl Friedrich), was born Aug. 3, 1817, in Vienna. After having been educated under the careful superintendence of his father, he entered the Austrian army as a colonel of infantry in 1837, and was transferred to the cavalry arm in 1839, and became a lieutenant-field-marshal in 1843. He learned the art of war from Radetzky. At this time the Austrian generals and staff officers had committed themselves blindly to the strategic method of the Archduke Charles, the tradition of whose practical soldiery survived only in Radetzky and a few others. Albert chose to follow Radetzky, and was thus saved from the

pseudo-scientific pedantry which brought defeat to the Austrian arms in 1859 and in 1866.

He fought under Radetzky as a volunteer throughout the campaign of 1848, having been present at the action of Pastrengo and the battles of Santa Lucia and Custoza. In the following campaign he applied for and obtained the command of a division in the 2nd corps (under d'Aspre), though his previous grade had been that of commander-in-chief. The splendid fighting of the corps at Novara was decisive, and Radetzky named d'Aspre, Count Thurn, and the archduke as the general officers worthy of the greatest rewards. In 1850 he became a general of cavalry, and in 1851 military and civil governor of Hungary, a position which he retained until 1860, when he was relieved at his own request.

Soon afterwards he was appointed to succeed Radetzky as commander-in-chief in Italy, and in 1863 he was promoted to the rank of field-marshal. When war became imminent in 1866, the archduke took command of the field army in Italy. For the story of the campaign of 1866 in Italy, see *ITALIAN WARS* (1848-70). The operations of the archduke, who disposed of considerably inferior forces, were crowned with success in the brilliant victory of Custoza (June 23), and his reputation as a general-in-chief was firmly established during only eight days of field operations, though it is possible that his chief of staff, Lieutenant-Field-marshal von John, contributed not a little to the success of the Austrian arms.

The result of Custoza was the retreat and complete immobilization of the whole Italian army, so that Albert was able to dispatch the greater part of his troops to reinforce the Bohemian army, when, after having been defeated by the Prussians, it fell back on Vienna. On July 10 the archduke was summoned to Vienna to take supreme command of the forces which were being collected to defend the capital, but peace was made before further hostilities took place. From this time, under various titles, he acted as inspector-general of the army.

Like his father, and with better fortune, he was called upon to reorganize the military system of his country on an entirely new plan, learned, as before, by defeat. The principle of universal short service, and the theory of the armed nation, were necessarily the groundwork of the reforms, and the consequent preparation of all the national resources for their task in war, by the superintendence of peace administration, by the skilful conduct of manoeuvres, was thenceforward the task of his lifetime. In 1870 he conducted the military negotiations preparatory to an alliance with France, which, however, was not concluded. He retained personal control of the army until his last illness, which he contracted at the funeral of his nephew Francis, ex-king of Naples. His only remaining brother, the Archduke Wilhelm, had died a few months before, as the result of an accident. He himself died Feb. 18, 1895. His only son died in childhood, and his nephew Archduke Frederick (born 1856) inherited his great possessions, including the Albertina, a famous collection of books, manuscripts, engravings and maps, founded by Duke Albert of Saxe-Teschen.

Among the military works of the Archduke Albert, *Über die Verantwortlichkeit im Kriege* created a sensation, and was translated into English and French. He also wrote *Gedanken über dem Militärgeist*; *Über die höhere Leitung im Kriege*; and *Kritische Betrachtungen über den Feldzug 1866 in Italien*. He was the principal editor of the military works of his father.

See Mathes v. Bilabruock, "Gedenkrede auf Weiland Sr. K. u. K. H. Erz. Albrecht," *Mil.-Wissenschaftl. Verein* (1895); Teuber, *F. M. Erz. Albrecht, ein Lebensbild* (Vienna, 1895); Duncker, *F. M. Erzherzog Albrecht* (Vienna and Prague, 1897).

ALBERT, also named ALEXANDRE MARTIN (1815-1895), the first industrial working-man to enter a government, was a member of the French Provisional Republican Government in Feb. 1848. He signed all decrees "ALBERT, *ouvrier*," and followed implicitly the guidance of Louis Blanc (*q.v.*). He was sentenced to ten years' deportation on political grounds in 1849. On his release he secured employment as a gasworker.

ALBERT, MADAME (*c.* 1805-1846), French actress, whose maiden name was Thérèse Vernet, was born of a family of players. Her grace, beauty, and distinction of manner made her the idol

of Paris, and her circle of admirers was widened by long tours of the provinces and abroad.

ALBERT, LAKE (A. NYANZA), Uganda, situated in $1^{\circ} 9'$ to $2^{\circ} 17'$ S., and $30^{\circ} 30'$ to $31^{\circ} 35'$ E. Its greatest length is 100m., its greatest breadth 22m., and its greatest depth 55ft. The area is approximately 1,640sq.m.; *i.e.*, about the size of Lancashire. The height of the lake surface above sea-level is given as 2,037ft., but this is liable to seasonal and other fluctuations.

The lake lies on the floor of the western branch of the Rift valley. Thermal springs occur at Kibiro, and again between the Murchison falls, on the Victoria Nile, and Wadelai. At Kibiro salt springs are exposed on the strand in the dry season, and give rise to a native trade in salt. At the southern end of Albert Nyanza is a wide plain, traversed by the Semliki river, which enters the lake through a swamp of tall weeds, chiefly ambach and papyrus. On both the eastern and western sides the walls of the Rift valley are close to the lake, the water in many cases washing the base of the cliffs. Elsewhere the narrow foreshore is thickly wooded. The ascent to the plateaux is generally by a series of abrupt steps. On the western side the mountains present many pointed and conical summits, some of which may be nearly 8,000 feet above the lake; on the eastern side the cliffs rise sharply for 1,000 to 2,000 feet. On either coast wild ravines, densely wooded, break the outline of the mountains. Through these gorges and over the plateau-edge fall magnificent cascades. Towards the north the hills recede from the coast and on both sides flats extend for distances varying from 5m. to 15m. On the eastern side, 92m. from the southern end of the Nyanza, the Victoria Nile enters the lake, here not more than 6m. across, through a wilderness of woods, the delta of the Nile extending over 4m. The mouth of the main stream is obstructed by a bar of its own formation; the current is sluggish; there are many side channels, and the appearance of the lake gives no hint that a great river has joined its waters. For 5m. or 6m. north of the junction of the Victoria Nile the lake suffers no material diminution in width. Then, however, the eastern and western shores approach each other, and a current is perceptible flowing north. The lake has become the Bahr-el-Jebel, or Mountain river, as this section of the Nile is called. Albert Nyanza is shallow; at its southern end the water for a considerable distance is not more than 3ft. deep. The deepest soundings give only 50ft. to 55ft., the average depth being 30 to 40 feet.

The Albertine Basin of the Nile.—Albert Nyanza receives the whole of the drainage of Edward Nyanza and the Semliki river, and with them forms the "Albertine" Nile system. Its waters, as stated above, mingle with those of the Victoria Nile. There is evidence of very considerable shrinkage in the size of these lakes. Within human times the level of Albert Nyanza appears to have been 1,000ft. higher than it is at present. The causes of this fall have not been fully explained. Both tectonic and climatic agencies may be involved. River erosion is probably also a complicating factor. In recent geological times the valley to the north of Edward Nyanza, then much larger than now, was blocked. The removal of the block led to the shrinkage of the lake and the formation of the Semliki, which found its way to the more northern lake—Albert Nyanza. Gradually the Semliki eroded its bed, and consequently the level of Edward Nyanza continued to fall. The process continues but is checked by the existence of the rock barrier which stretches across the Semliki. This stream leaves Edward Nyanza at its north-west end in $0^{\circ} 8' 30''$ S., and after a course of about 160m. enters Albert Nyanza in $1^{\circ} 9'$ N. In its upper and in its lower course the river flows either through high alluvial plains, in which it has scored a deep channel, or across swamp land. In the middle section, which has a length of some 75m., the river runs in a deep narrow valley covered with the densest forest. On the west this valley is bounded by the Congo mountains, which form the wall of the Rift valley, on the east by the mighty range of Ruwenzori, whose heights tower over 16,000ft. above sea-level. In this length of 75m. the river falls in cataracts and rapids over 800 feet.

Albert Nyanza, on the other hand, is threatened in the distant future with destruction from another cause—the filling of its

bed by the alluvium poured into it by the Semliki, the Victoria Nile and other streams. The Semliki receives directly or indirectly the whole of the drainage of Ruwenzori, and also that of the eastern face of the Congo mountains as well as the drainage basin of Edward Nyanza. The Semliki, as it emerges from the region of forest and cataracts, and deposits much of its burden, becomes sluggish as its slope flattens out. This process has formed a large plain at the south end of Albert Nyanza, which has seriously encroached upon the lake. At the northern end of the lake the sediment brought down by the Victoria Nile is producing a similar effect. Nyamsasi, which was an island at the south-west end in 1889, has become a peninsula. Islands which in 1876 were on the east coast no longer exist; they now form part of the foreshore. On the other hand, the shrinkage of the lake level caused the appearance in 1885 of an island where in 1879 there had been an expanse of shallow water. It seems probable that, in a period geologically not very remote, the "Albertine" system will consist of one great river, extending from the northern slopes of the Kivu range, where the Ruchuru has its rise, to the existing junction of the Victoria Nile with Albert Nyanza.

The combined drainage area, including the water surface of Edward Nyanza, the Semliki and Albert Nyanza, is some 16,600 sq.m. Throughout this area the rainfall is heavy (40in. to 60in. or more per annum), the volume of the Semliki in flood being not less than 700cu.m. per second. Of the water received by Albert Nyanza annually (omitting the Victoria Nile from the calculation) between 50% and 60% is lost by evaporation, whilst 24,265,000,000cu.m. are annually withdrawn by the Bahr-el-Jebel. The "Albertine" system plays a comparatively insignificant part in the annual flood rise of the White Nile, but to its waters are due the maintenance of a constant supply to this river throughout the year.

Discovery and Exploration.—Albert Nyanza was first reached by Samuel Baker on March 14, 1864, near Vacovia, a small village of fishermen and salt-makers on the east coast. Albert Nyanza was entered on his map as a vast lake extending about 380m. But the circumnavigation of the lake by Gessi Pasha (1876), and by Emin Pasha in 1884, showed that Baker had been deceived as to the size of the lake. The lake forms part of the (British) Uganda Protectorate, but the north-west shores were leased in 1894 to the Congo Free State. Of this leased area a strip 15m. wide, giving the Congo State a passageway to the lake, was to remain in its possession after the determination of the lease. (See also NILE.)

ALBERT OF AIX (fl. c. A.D. 1100), historian of the first crusade, was canon and *custos* of the church of Aix-la-Chapelle. He wrote a *Historia Hierosolymitanae expeditionis* or *Chronicon Hierosolymitanum de bello sacro*, a work in 12 books, between 1125 and 1150. This book gives the history of the first crusade and of the Latin Kingdom of Jerusalem down to 1121. It was well known during the middle ages, and was largely used by William, archbishop of Tyre, for the first six books of his *Belli sacri historia*. The first edition of the history was published at Helmstadt in 1584, and a good edition is in the *Recueil des historiens des croisades*, tome iv. (Paris, 1841-87).

See M. Pigeonneau, *Le Cycle de la croisade et de la famille de Bouillon* (1877); F. Krebs, *Zur Kritik Alberts von Aachen* (Muenster, 1881); H. von Sybel, *Geschichte des ersten Kreuzzuges* (Leipzig, 1881); B. Kugler, *Albert von Aachen* (Stuttgart, 1885); F. Vercauysse, *Essai critique sur la chronique d'Albert d'Aix* (Liège, 1889).

ALBERTA, the most westerly of the three prairie provinces of Canada and the most recently developed, is bounded on the south by the U.S. along the 49° N. lat., on the east by Saskatchewan along the 110° W. long., on the north by lat. 60° and on the west by British Columbia along the Rocky mountains water-parting to lat. 54° and thence long. 120° W. It contains portions of three physiographical provinces, viz., that of the Rocky mountains and foothill region, where the country is mountainous and

rugged, and the strata much disturbed; that of the great plains, where the land forms are tabular and lower, and the strata are usually flat lying; and lastly, a small area of the Laurentian shield in the extreme north-east about Lake Athabasca. The true foothill country occupies a narrow belt in the south-west wholly more than 4,500ft. above sea-level, and characterized by sharp, parallel north-west to south-east ridges from 5,000 to 7,000ft. in height. The front range of the Rockies in Alberta has an average height of 8,000 to 9,000ft., with many peaks over 10,000 feet. All the rest of Alberta is a land of plains and plateaux. In general this land sinks to the north and east from a general level in the south-west of about 3,500ft. to 600ft. about the Slave river in the extreme north-east. This descent is not gradual, however, but takes place chiefly between a high plateau developed on Cretaceous and Tertiary rocks (2,000 to 3,000ft.), which cover most of the province, and a lowland (600ft.) developed on Palaeozoic and Archaean rocks, in the extreme north-east. The zone of rapid

descent runs diagonally from about Fort MacMurray on the Slave river, lat. 56° 45', to about where the Hay river leaves the province in the north. The Athabasca and Peace rivers make great embayments into this upland, the flanks of which are known as the Cutknife (2,400ft.), Caribou (3,300ft.) and Birch (2,500ft.) mountains (i.e., plateaux). Near the head of these embayments the Hay, Peace and Athabasca rivers are interrupted by rapids. South of this scarp line of the extreme north, the general surface level of the rest of Alberta is about 2,000 to 2,500ft. but is studded with residual plateaux a few hundred feet higher, developed on Tertiary rocks. Such are the Swan hills and Hand hills, and in the extreme south, the Milk River ridge and Cypress hills—the last mentioned rising to 4,500ft. with particularly rough topography. The developed prairie portion of the province lying between Edmonton and Lethbridge drains eastward by the north and south Saskatchewan river system. The larger, forested and undeveloped northern portion drains north by the Athabasca and Peace river systems. On the main plateaux, the river flood-plains are enclosed by precipitous walls, often several hundred feet high. Apart from the dissected edges of the residual plateaux, and the sharp trenches of the rivers, the prevailing relief is flat to gently rolling. In the drier southern parts of the province the plateaux and river scarps develop a bad-land topography.

The larger part of Alberta is forested, chiefly with conifers, but most settlement has taken place in the southern prairie area. The forest line runs west of the Edmonton-Calgary-Macleod line, and the northern boundary is about the line of the North Saskatchewan eastward from Edmonton. On the inner side of these limits the prairie is invaded by a varying width of grove country, with scattered and usually small wood belts, chiefly of poplar and birch. Within this again lies the true prairie. Prairie and grove form less than one quarter of the province, but they are the scene of most of its development.

Climate.—The extreme continental type prevails. The winters are very severe, but weeks of very low temperature are frequently interrupted by startling increases. This is due some-

times to warm southerly winds; sometimes to a Chinook effect with westerly winds. The summers show rather higher average shade temperatures than those obtaining in the same latitudes of western Europe. Actually the air is clearer, the sun temperature higher, the daily range greater, and the tendency to heat wave greater. The precipitation is everywhere small but rises to over 20 in. at the borders of the foothills. Elsewhere it varies from 11 in. to 16 in. over most of the province, the driest areas occurring in a broad belt of prairie land to the east of Calgary and Lethbridge. This is also in general the area of highest summer temperature and longest growing seasons. Fortunately more than 65% of the precipitation is between May and September. Snowfall is light and is frequently rapidly cleared by the Chinook in the south.

Topography.—The whole of Alberta was glaciated, with the usual results of a rearranged river system, a ground-till thinning out somewhat on the plateau levels, some areas of rough morainal topography, and many irregularly scattered lakes. Of these last some in the south-eastern dry belt are alkaline. The soils developed on the glacial till over most of the prairie area, under the influence of the climate and natural vegetation, are dark brown loams of great fertility. There are scattered areas of poor land, especially in the rough topography of the Milk River ridge and Cypress hills, and in the south, about the borders of Saskatchewan; but the greater part of the prairie and grove areas is exceedingly fertile. The Porcupine hills and Bow river plateaux just east of the foothills, together with some of the Milk river plateau, are important ranch lands. The grass sun-cures *in situ*, but to ensure good results some winter feed in addition must be forthcoming. This (among other crops) is provided by the great Alberta irrigation works which have been made in the dry belt east of Calgary and Lethbridge. These works tap the Bow, Old Man, and St. Mary rivers where they emerge from the foothills (and at additional points lower down) and render irrigable an enormous area in a district where the average rainfall is less than 14 in. and very variable. About 20% only of the land which existing works have rendered irrigable is actually irrigated. The percentage is highest in the Lethbridge area, where there is a long growing season and diversified irrigated crops. The western Canadian Pacific railway irrigation system is only on the verge of the arid belt, and the farmers, if conditions look promising, frequently do not irrigate but trust to the rainfall for their wheat crop. In the northern grove belt, and in the area of cleared bush, north and west of Edmonton, mixed farming predominates. In the centre and south of the developed area purely wheat farming is still the rule. Alberta, the last of the prairie provinces to be developed, has made enormous strides in the last few years in farm production. On the middle Peace river in northern Alberta some rich open prairie forms a kind of oasis in the surrounding forests. The growing season, too, is longer (120 days) than in surrounding areas, and the soils are good. Recent settlement has been attracted to this country, which is now connected up by rail with Edmonton. This is the most northerly area (lat. 56°) of considerable farming settlement on the continent. Excellent grain and dairy produce is obtained. An outlet is to be sought across the Rockies to join the Prince Rupert line. There is a growing tendency for wheat shipment to take place via Vancouver instead of Winnipeg.

At three horizons in the Cretaceous sands and shales, coal-bearing formations occur; viz., in the Edmonton, Belly river, and Kootenay formations. The Kootenay (lower Cretaceous coals)

are accessible only when brought to the surface in the Rocky mountains and foothill belt in elongated, detached basins, which run parallel to the Rockies. These coals are bituminous and sometimes anthracitic. The structure however is disturbed and the topography difficult. Eastward of the Rockies the rocks are little disturbed, though a major syncline and anticline determine the accessibility of coal seams in the Belly river and Edmonton formations. The seams are thick and persistent over large areas, and little disturbed. The coals pass from sub-bituminous in the west to lignite in the east. Along the belts of accessible coal, mining occurs where there are railway connections. The reserves are enormous, and the present market is for the railways, for power stations in the larger towns, and for domestic fuel. Coal is sent over the border to Saskatchewan, and if freights can be brought low enough may eventually come into competition with American coals in populous southern Ontario. The chief mining areas at present are the Crow's Nest, Drumheller, Lethbridge, Edmonton and Mountain Park fields. Nearly six million tons were mined in 1925. Natural gas is piped to Edmonton, Calgary and Medicine Hat from the Viking, Bow Island, and Medicine Hat fields respectively. There are promising oil developments in the Turner Valley field in the foothills south-west of Calgary. Alberta has 475,000 h.p. water power resources (calculated at ordinary minimum flow) of which 34,000 h.p. is developed.

Transport.—There is an extensive development of railway now in the prairie and grove region, and the Rockies are crossed at three points, viz., the Yellow Head pass (C.N.R.), Kicking Horse pass (C.P.R.) and Crow's Nest (C.P.R.). The first two are through routes to Vancouver, and have, in addition to their normal traffic, a heavy summer tourist traffic. The last leads, by combined lake and rail routes, to the British Columbia southern mining and fruit growing valleys. Population, 1931, 731,605. The chief cities are Edmonton (capital, pop., 79,197); Calgary (83,761); Lethbridge (13,489) and Medicine Hat (10,300).

POPULATION AND RACIAL ORIGIN (1926) 607,599

British	350,086	Ukrainian	35,819
German	47,114	French	31,582

History.—Alberta was administered as a part of the Northwest Territories after 1870 and received provincial status in 1905. Until the coming of the railway in 1883 there was little settlement, though the neighbourhood of Edmonton had acquired some importance from the collecting and furnishing of fur company stores situated on the navigable Saskatchewan near this point.

Administration.—Alberta sends a quota of senators (six nominated for life) and 12 members of the House of Commons, to the Dominion Government; but has as well, like the other prov-

inces, its own separate parliament and administration with a lieutenant-governor, appointed by the governor-general, at the head of the executive. Alberta has one legislative assembly consisting of 60 directly elected members and an executive council. Woman suffrage is established in the province. Among the matters assigned exclusively to provincial legislators are: the amendment of the provincial constitution, direct taxation for revenue, borrowing, education, local works and undertakings, etc. Edmonton is the seat of government. The provincial government controls education. Primary and secondary education is free and non-sectarian, though in certain circumstances minority elementary schools are established. There is a university at Edmonton and normal schools at Calgary and Camrose. (L. R. J.)

ALBERT EDWARD NYANZA: see EDWARD, LAKE.

ALBERTI, DOMENICO (c. 1710–1740), Italian musician, achieved unawares something like immortality in musical history as the writer of dozens of sonatas in which the melody is supported from beginning to end by an extremely familiar, but nowadays little-esteemed, formula of arpeggio accompaniment, consequently known as the Alberti bass.

ALBERTI, LEONE BATTISTA (1404–1472), Italian painter, poet, philosopher, musician and architect, was born in Venice on Feb. 18, 1404. He was so skilled in Latin verse that a comedy he wrote in his twentieth year, entitled *Philodoxius*, deceived the younger Aldus, who edited and published it as the genuine work of Lepidus. In music he was reputed one of the first organists of the age. At Rome he was employed by Pope Nicholas V. in the restoration of the papal palace and of the foundation of Acqua Vergine, and in the ornamentation of the magnificent fountain of Trevi. At Mantua he designed the church of Sant' Andrea, at Rimini the Church of San Francesco, which is generally esteemed his finest work, and in Florence the principal façade of the church of Santa Maria Novella, as well as the palace now known as the Palazzo Strozzi. His most important treatise is that on architecture, *De Re Aedificatoria*, which was translated into Italian, French, Spanish and English.

See Passerini, *Gli Alberti di Firenze* (1869–70); Mancini, *Vita di Alberti* (Firenze, 1882); V. Hoffmann, *Studien zu Leon Battista Alberti's zehn Büchern: De Re Aedificatoria* (Frankenberg, 1883).

ALBERTINELLI, MARIOTTO (1474–1515), Italian painter, was born in Florence, and was a fellow-pupil and partner of Fra Bartolommeo, with whom he painted many works. His chief paintings are in Florence, notably his masterpiece, the "Visitation of the Virgin" (1503) at the Uffizi.

ALBERTINI, LUIGI (1871–), Italian journalist and politician, was born at Ancona Oct. 19, 1871, and after graduating in law took to journalism. In 1896 he joined the staff of the Milan newspaper, *Il Corriere della Sera*, and in 1909 became editor and chief proprietor. Under his guidance *Il Corriere* became the foremost journal in Italy. In 1914 Albertini was nominated senator and showed himself a convinced interventionist. After the War *Il Corriere* was steadily anti-Socialist. Albertini at first sympathized with Fascism, but when the movement began to aspire to seize power by violence he opposed it. When the Black Shirt *squadre* occupied Milan they forced *Il Corriere* to suspend publication, but Mussolini afterwards revoked the suspension. In parliament Albertini made several important speeches against the government and, after the Matteotti affair, against Mussolini in particular. His paper was frequently confiscated under a decree restricting the liberty of the press. In Nov. 1920, owing to the difficult position of *Il Corriere*, the company was dissolved, Albertini bought out, and a new director appointed.

ALBERTITE, a pyrobitumen (see BITUMEN) so named from the type occurrence in Albert county, New Brunswick. It is jet black in colour, has a brilliant lustre and a conchoidal to hackly fracture. It occurs typically in veins up to many feet in thickness and is a derivative of petroleum. (J. R.)

ALBERT LEA, a city of Minnesota, U.S.A., about 97 m. S. of St. Paul; the county seat of Freeborn county. It is on the Jefferson highway, Blackhills Trail, is the northern terminus of

the Illinois Central Railroad, and is served also by the Rock Island, the Chicago, Milwaukee and St. Paul, and the Minneapolis and St. Louis railways. It is pleasantly situated between Lake Albert Lea and Fountain lake. The population was 8,056 in 1920, of whom 1,271 were foreign-born white; in 1930, 10,169.

The manufactures include road-building machines, sprayers for fruits and vegetables, tools, camp stoves, and barn equipment. Thousands of chickens, hatched in electrically controlled incubators, are shipped to all parts of the country. Butter is the leading product of the surrounding country, and the Minnesota State Experimental Creamery was established in Albert Lea in 1911. The two lakes and 16,000 ac. of surrounding territory have been placed in a game refuge, where hunting is forbidden.

The city and the lake owe their names to Lieut. Albert Miller Lea (1808–91), a West Point graduate (1831), who was the topographer of a U.S. Government exploring party. His report was published in 1836. The first post office was established here in 1855, and the city received its charter in 1878.

ALBERT MEDAL, a British decoration instituted in 1866 as an award for signal acts of bravery in saving life at sea, and extended in 1877 to acts of bravery on land. The conditions governing the award were amended in 1905. There are two classes, each with two divisions. The medal, which is in gold for the 1st class and bronze for the 2nd, is oval, and bears the monogram V.A. The ribbon is either blue (for bravery at sea) or crimson (for bravery ashore) with white vertical stripes.

ALBERT PIKE HIGHWAY, a western thoroughfare, running from Hot Springs, Arkansas, through the Ozark mountains to Colorado Springs, Colorado. In 1928 it was graded and improved throughout most of its 1,000-mile length, but had little pavement. Ft. Smith, Muskogee, Tulsa, Dodge City, La Junta and Pueblo are some of the cities that lie along its path. It was named after Albert Pike, American author, soldier and explorer who first passed over the route in an expedition to Santa Fé.

ALBERTUS MAGNUS, ALBERT OF COLOGNE (?1206–1280), scholastic philosopher called *doctor universalis*. Albert was born of the family of the counts of Bollstädt, at Lauingen, in Suabia. In 1223 he joined the Dominican order, and after teaching in turn at Cologne, Hildesheim, Freiburg, Ratisbon, Strasbourg, and again at Cologne, was sent to Paris from 1245–48, and there acquired great fame. (Roger Bacon, who was by no means friendly towards Albert, speaks of him as "the most noted of Christian scholars.") When he returned to Cologne in 1248 to organize the *studium generale*, Thomas Aquinas, who had been under his direction at Paris, went with him. From 1254–57 he was provincial of the German province, during which time he defended the Mendicants against the University of Paris and its spokesman, William of St. Amour. From 1260–62 he held the bishopric of Ratisbon. From that date to 1270, when he returned to Cologne as a *lector*, he seems to have been travelling about preaching a crusade in Germany and Bohemia, and undertaking various other ecclesiastical missions in Würzburg and Strasbourg. In 1277 he returned to Paris to defend the doctrines of Aquinas against the condemnations of Bishop Tempier. Albert's works, which were mostly completed before 1256, were published in 21 folio volumes by Jammy at Lyons in 1651, and reprinted in 36 volumes by Borguet (Paris, 1890). They include paraphrases of all of Aristotle's works, a commentary on the *Sentences* of Peter Lombard, an incomplete *Summa Theologiae*, a treatise against Averroes, and the curious *De Causis et Processu Universitatis*—a work of Neoplatonic colouring.

Albert has a remarkable affinity with the early Franciscan philosophers of Oxford; thus, his love of experimental science, and his knowledge of geography, astronomy, medicine, zoology and botany, are strongly reminiscent of Grosseteste and Bacon, while his interweaving of Aristotelian, Arabian, Jewish, Neoplatonic and Augustinian elements bears a close resemblance to the system of Thomas of York. However, as far as his Dominican successors are concerned, Albert's chief influence seems to lie in his successful propagation of an esteem for Aristotle. Hence his project of "adapting Aristotle to the use of the Latin races" was fulfilled in spite of the intense distrust of Aristotle that had been

aroused by the Paris condemnations of his works on natural science and metaphysics in 1210, 1215, 1231 and 1245.

Michael, *Geschichte d. deutschen Volkes vom 13. Jahrh.* (1903) v. iii, p. 445 seq. (for Albert's scientific interests); A. Schneider, *Die Psychologie Alberts d. Gr.* (1906); C. Baeumker, *Witelo* (1908) (for Albert's Neoplatonism); H. Lauer, *Die Moralthologie Alberts d. Gr.* (1911); P. Mandonnet, *Siger de Brabant* (1911); L. Gaul, *Alberts des Grossen Verhältnis zu Plato* (1913); G. von Hertling, *Albertus Magnus, Beiträge zu seiner Würdigung* (1914).

ALBERUS, ERASMUS (c. 1500–1553), German humanist and poet, was born at Sprendlingen, near Frankfort, and died at Neubrandenburg on May 5, 1553. He was almost the only member of Luther's party who commanded an effective weapon of satire. He ridiculed the Franciscan order in his *Barfüsser Mönche Eulenspiegel und Alkoran* (1542, preface by Luther), and gave his views on church and state in a collection of fables entitled *Buch von der Tugend und Weisheit* (1550). Some of his hymns are used in the Lutheran hymnal.

BIBLIOGRAPHY.—*Das Buch von der Tugend und Weisheit* has been edited by W. Braune (1892); the 16 *Geistliche Lieder* by C. W. Stromberger (1857). Alberus's prose writings have not been reprinted in recent times. See F. Schnorr von Carolsfeld, *Erasmus Alberus* (1894).

ALBI, a city of south-west France, in the department of Tarn, 48m. N.E. of Toulouse, on a branch line of the Southern railway. Pop. (1926) 21,994. It occupies a commanding position on the left bank of the Tarn, where its valley broadens as it emerges from the high *Plateau Central* towards the plain of Toulouse; a bridge crosses to La Madeleine (a suburb).

Albi (*Albiga*) was capital of the Gallo-Roman Albigenes, and later of the viscounty of Albigeois, a fief of the counts of Toulouse. From the 12th century onwards its bishops encroached on the authority of the viscounts and, after the Albigenian War, lost their estates, which passed ultimately to the Crown. By a convention (1264), the chief temporal power was granted to the bishops. A nucleus of narrow, winding streets is surrounded by boulevards, beyond which lie modern quarters. The cathedral of Sainte Cécile, a fine Gothic fortress-church built in 1277–1512, is without transepts or aisles; the rood-screen and the choir-enclosures (about 1500) are masterpieces. The 14th-century archbishop's palace to the north-east is fortified.

The church of St. Salvi belongs to the 13th and 15th centuries. There are dye-works, cement-works, coal-mines, glass-works and important flour-mills. Hats, cloth fabrics, umbrellas, artificial silk and agricultural implements are also made. Trade is in wheat, wine, and prunes. Albi is the seat of an archbishop (1678), a prefect, and a court of assizes. It has tribunals of first instance and of commerce, a board of trade arbitrators and a chamber of commerce.

ALBIA, a city of Iowa, U.S.A., 68m. S.E. of Des Moines, in a fertile farming and stock-raising district and in the Albia coal-field; the county-seat of Monroe county. It is a junction point of the Burlington, the Wabash, and the Minneapolis and St. Louis railways, and is the northern terminus of the Iowa Southern Utilities Company. It has several industrial plants, and is an important distributing centre for the coal and agricultural products of the region. The population in 1920 was 5,067; in 1930, 4,425.

ALBIGENSES, the usual designation of the heretics—and more especially the Catharist heretics—of the south of France in the 12th and 13th centuries. This name appears to have been given to them at the end of the 12th century, but the designation is hardly exact, for the centre of the movement was at Toulouse and in the neighbouring districts rather than at Albi (the ancient *Albiga*). The heresy, which had penetrated into these regions probably by trade routes, came originally from eastern Europe. The name of Bulgarians (*Bougres*) was often applied to the Albigenes, and they always kept up intercourse with the Bogomil sectaries of Thrace. Their dualist doctrines, as described by controversialists, present numerous resemblances to those of the Bogomils (*q.v.*), and still more to those of the Paulicians, with whom they are sometimes connected. It is exceedingly difficult,

however, to form any very precise idea of the Albigenian doctrines, as our knowledge of them is derived from their opponents, and the very rare texts which have come down to us, emanating from the Albigenes (e.g., the *Rituel cathare de Lyon*, ed. by Cunitz, Jena, 1852, and the *Nouveau Testament en provençal*, ed. by Clédat, Paris, 1887), contain very inadequate information concerning their metaphysical principles and moral practice. What is certain is that, above all, they formed an anti-sacerdotal party in permanent opposition to the Roman Church, and raised a continued protest against the corruption of the clergy of their time. The Albigenian theologians and ascetics, the Cathari or *perfecti*, known in the south of France as *bons hommes* or *bons chrétiens*, were few in number; the mass of believers (*credentes*) were perhaps not initiated into the Catharist doctrine; at all events they were free from all moral prohibition and all religious obligation, on condition that they promised by an act called *convenenza* to become "hereticized" by receiving the *consolamentum*, the baptism of the Spirit, before their death or even *in extremis*.

The first Catharist heretics appeared in Limousin between 1012 and 1020. Protected by William IX., duke of Aquitaine, and soon by a great part of the southern nobility, the movement gained ground in the south, and in 1119 the Council of Toulouse in vain ordered the secular powers to assist the ecclesiastical authority in quelling the heresy. The people were attached to the *bons hommes*, whose asceticism and anti-sacerdotal preaching impressed the masses, and the movement maintained vigorous activity for another hundred years, until Innocent III. ascended the papal throne. At first he tried pacific conversion; but his envoys had to contend not only with the heretics, the nobles who protected them and the people who listened to them and venerated them, but also with the bishops of the district, who rejected the extraordinary authority which the pope had conferred upon his legates. At last (1209) the pope ordered the Cistercians to preach the crusade against the Albigenes. This implacable war, which threw the whole of the nobility of the north of France against that of the south, and destroyed the brilliant Provençal civilization, ended, politically, in the Treaty of Paris (1229), which destroyed the independence of the princes of the south, but did not extinguish the heresy, in spite of the wholesale massacres of heretics during the war. The Inquisition, however, operating unremittingly in the south at Toulouse, Albi and other towns during the whole of the 13th century and a great part of the 14th, succeeded in crushing it. There were indeed some outbursts of rebellion, some fomented by the nobles of Languedoc (1240–42) and others emanating from the people of the towns, who were embittered by confiscations and religious persecutions, but the repressive measures were terrible. In 1245, the royal officers assisting the Inquisition seized the heretical citadel of Montségur, and 200 Cathari were burned in one day. Moreover, the Church decreed severe chastisement against all laymen suspected of sympathy with the heretics (Council of Narbonne, 1235; Bull *Ad extirpanda*, 1252).

Hunted down by the Inquisition and now abandoned by the nobles of the district, the Albigenes became more and more scattered, hiding in the forests and mountains, and only meeting surreptitiously. The sect, moreover, was exhausted and could find no more adepts in a district which, by fair means or foul, had arrived at a state of peace and political and religious unity.

BIBLIOGRAPHY.—See C. Schmidt's *Histoire de la secte des Cathares ou Albigeois* (1849), which is still the most important work on the subject. On the ethics of the Catharists, see Jean Guiraud, *Questions d'histoire et d'archéologie chrétienne* (1906); and P. Alphonse, *Les idées morales chez les hétérodoxes latins au début du XIII^e siècle* (1903). See also under CATHARS.

ALBINISM: see PIGMENTS OF SKIN AND HAIR.

ALBINO, a biological term (Lat. *albus*, white) for a pigmentless individual of a pigmented race. Pigmentation depends upon the presence and interaction in the tissues of colour-bases, chromogens, colourless in themselves, and ferments or enzymes which, acting upon the colour-bases, yield coloured products. If, therefore, either of these ingredients of pigmentation is absent from the constitution of an individual, it must perforce remain pigmentless, albinotic, even though in the environment in which it

ALBINO: VARIATIONS OCCURRING IN CRUSTACEAN, RODENT AND BIRD FAMILIES

1. Lobster with the normal blue pigment almost entirely lacking
2. Tree porcupine, American rodent in which albinism is rather common
3. White peacock whose tail is like watered silk in appropriate light
4. Albino squirrel caught in Sussex, England, uncommon in the wild state

lives there are agents, such as sunlight, which are known to stimulate the production of pigment in the tissues of animals and plants exposed to their action. An albino is an individual whose tissues lack the power to elaborate either the ferments or the colour-bases.

In man the general colour of the skin ranges from the fair, almost pigmentless, condition of the Scandinavian to the almost ebony blackness of the natives of certain parts of Africa. These differences have been employed in the classification of races into white, yellow, red, brown, and black. The colour of the skin proper is creamy white. To this is added a tinge of yellow due to the presence of a yellow pigment in the skin. A further ingredient is black, due to the presence of minute granules of melanin, itself sepia in colour but, in masses, so completely absorbing the light that it appears black. Lastly, the red colour of the blood circulating in the minute vessels of the skin adds its tint. It is possible, by using a spinning top with a combination of these colours, white, yellow, red, and black in different proportions, to match any particular skin colour, and it is found, when this is done, that in all pigmented skins all these four colours can be identified, and that different proportions of the yellow and the black in combination correspond to different racial skin colorations. The relative proportions of these two pigments vary greatly in different individuals and in different regions of the body of one and the same individual.

Albinism is the condition, as estimated by this test, in which the black pigment is absent and in which the yellow is present only in relatively small amount.

The eyes of the albino are pink, this colour being the red of the blood circulating in the retinal blood vessels, as seen through the transparent tissues in front. The eyes are extremely sensitive to light and so the eyelids are kept partially closed, while blinking and a general wrinkling of the skin around the eyes are associated conditions which give to the albinotic individual a characteristic appearance. The hair on all parts is white, and all tissues, such as the brain and spinal cord, which in the normal individual are more or less pigmented, are in the albino completely devoid of this melanin.

In the normal individual this black pigment would seem to serve a useful purpose. In the case of the pigmented eye, the intensity of the light falling upon the retina is adequately diminished by the absorbing power of the retinal pigment, and this same melanin in the skin and hair, it is assumed with reason, protects the individual from the rays of the sun in tropical climes. The albino is seriously embarrassed in consequence of its deficiency, the albino animal much less so than the plant, however. Commonly in the breeding of corn or sorghum, when the self-fertilized seeds from an apparently normal green plant are sown, it is found that amongst the seedlings a number of spindling white plants make their appearance only to wither. They die because they lack the pigment chlorophyll, so essential in the manufacture of food, and therefore in the life of the plant. When the seeds of such an albino-producing plant are carefully sown and the number of chlorophyll-possessing and chlorophyll-lacking seedlings are counted, it is found that the greens outnumber the albinos by about three to one. From this it is known that the parent plant was heterozygous for its character green, that albinism in plants as in animals behaves in inheritance as a simple Mendelian recessive, and that in the case of these plants this character in the homozygous condition (*see MENDELISM*) is lethal, since in the absence of chlorophyll the plant cannot assimilate its food.

Albinism has been recorded in the great majority of the species, breeds, and varieties of domesticated animals and of cultivated plants. There are many records of instances of the condition among wild mammals and birds. In the case of mankind it has been observed in most races and probably occurs in all. Its frequency is not known, but it is estimated at perhaps one in 10,000. To-day it is possibly most frequent among the Indians of Arizona and Mexico. Whatever may be the exact frequency of the albinotic in a species, it is certain, since the condition behaves as a Mendelian recessive, that there are far more "car-

riers" than affected individuals in any race in which albinos appear, and that though originally the condition made its appearance as a "sport" or mutation, resulting from some definite change in the hereditary material of some one individual, since that time its reappearance in the stock is the result of the shuffling and reshuffling of the hereditary factors in their transmission from generation to generation and of the matings of apparently normal individuals who, however, are heterozygous for this particular character, not showing the taint but carrying it and transmitting it to their progeny.

The differently coloured races of a species all have albinotic strains and these may each possess the colour-bases or the ferments of the particular race to which it belongs. Albinos are all alike in that they are unpigmented, but they differ remarkably in respect of their unexpressed pigmentation. Properly planned breeding experimentation reveals the hidden. Pigmented races are not coloured uniformly: there is always some suggestion of a differential regional distribution of pigment, some indication of a pattern, and breeding experimentation has shown that the hereditary factors for the different patterns are transmitted from one generation to another quite independently of those which relate to the actual colour of the skin or coat. Thus it is that an albino that cannot exhibit a pattern because it has no colour can possess in its hereditary constitution factors for one or other of the various patterns. It is known, for example, that when a pure-bred self-coloured mouse is mated with an albino, the pattern of the coats of the offspring is determined by hereditary factors that are known to be absent from the self-coloured stock and to be present in the stock out of which the albino was derived.

So far, complete albinism only has been discussed. Partial albinism is also known, and a study of this condition reveals the fact that the interaction of colour-base and colour-developer is conditioned by such agencies as temperature. The Himalayan rabbit is an excellent example of partial albinism. In this breed the eye is pink and the fur of the body is unpigmented, but the ears, legs, tail, and nose are black. It has been shown that if an area of the white-furred body is shaved and the animal kept in the cold ($5-9^{\circ}\text{C}$) the new fur that grows is black, whereas if the animal is kept in a warmed room, the new fur is white as before. The baby coat of the Himalayan is all white and the pattern develops after a few weeks when the young are moving freely about. But if the naked baby rabbit is taken from the nest for about ten minutes on two successive days and exposed to a temperature of about 17°C , and especially if it is sponged with cold water, the fur when it is developed later is black all over the body. It follows that the essential ingredients for pigmentation are present in all parts of the skin but that ordinarily the pigment is elaborated only in certain well-defined areas. The Himalayan is a self-coloured race, but the power to elaborate pigment at ordinary temperatures differs in different regions of the body, certain areas being albinotic because normally the temperature of these parts is not that at which the enzyme and colour-base which are undoubtedly present can in their interaction yield pigment.

In certain animals such as the arctic fox, the stoat, ermine, and several hares, and in certain birds, the ptarmigan for example, the pigmented pelage or plumage of the summer and autumn is replaced in the winter by a white one. In the case of the hare, it is held by some that the autumn coat is moulted completely and that the winter coat is a new growth; others hold that there is no moulting but that the autumn coat itself becomes unpigmented; still others are of the opinion that both processes are involved, a whitening of the old fibres and a new growth of non-pigmented fibres. In the ptarmigan the pigmented feathers certainly become white. It is probable that in the hare and similar forms the whiteness is due to the presence of air in the pigmented fibres and consequently to the irregular reflection of the light from the surfaces of these air bubbles. In the case of the ptarmigan it is possible that the whiteness of the winter plumage is due to a seasonal increase in the activity of the thyroid gland, for it is established that if the active principle of the thyroid gland is administered to pigmented domestic fowls, the new feathers as they grow tend to be non-pigmented. It has not yet been shown conclusively that

this seasonal change from the pigmented to the non-pigmented condition is to be regarded as an instance of seasonal albinism.

Occasionally albinotic frogs or axolotls are recorded, but it is doubtful whether all these cases are true examples of albinism. It is more probable that they are individuals in which the pituitary gland or hypophysis at the base of the brain is abnormal; for experiment has shown that if this gland is removed from these animals, the pigment cells in their skin no longer expand and that therefore the animals must preforce remain very pale in colour. An injection of the active principle of the gland, pituitrin, turns them coal-black almost at once.

(F. A. E. C.)

ALBINOVANUS PEDO, Roman poet, flourished during the Augustan age. He wrote a *Theseis*, referred to in a letter from his friend Ovid (*Ex Ponto*, iv. 10), epigrams which are commended by Martial (ii. 77, v. 5) and an epic poem (*cf.* Quintilian x. i. 90) on the exploits of Germanicus under whom he probably served (*Tac. Ann.*, i. 60). This may have been used as a source by Tacitus. All that remains of his works is a beautiful fragment, preserved in the *Suasoriae* (i. 15) of Seneca, describing the voyage of Germanicus (A.D. 16) through the river Ems to the Northern Ocean.

Three elegies were formerly attributed to Pedo by Scaliger; two on the death of Maecenas (*In Obitum Maecenatis* and *De Verbis Maecenatis moribundi*), and one addressed to Livia (*Consolatio ad Liviam de Morte Drusi* or *Epicædion Drusi*, usually printed with Ovid's works); but it is now generally agreed that they are not by Pedo. The *Consolatio* has been put down as the work of a 15th century Italian imitator, there being no mss. and no trace of the poem before the publication of the *editio princeps* of Ovid in 1471. There is an English verse translation of the elegies by Plumptre (1907).

See Haupt, *Opuscula*, i. (1875); Bährens, *Poetae Latini Minores* (1879) and *Fragmenta Poetarum Latinorum* (1886); Haube, *Beitrag zur Kenntnis des Albinovanus Pedo* (1880).

ALBINUS, BERNARD SIEGFRIED (1697-1770), was born at Frankfurt-on-the-Oder, and from 1718 to his death on Sept. 9, 1770, occupied the chair of anatomy, surgery and medicine at Leyden. He was the first to show by injections the connection of the vascular systems of the mother and the foetus. He also edited with Boerhaave the works of Vesalius and of Harvey. But he is chiefly famed for the excellent drawings in his *Tabula sceleti et musculorum corporis humani* (Leyden, 1747). His *De ossibus corporis humani ad auditores suos libellus* appeared at Leyden, 1726.

ALBION, the most ancient name of the British Isles, generally restricted to England (in Ptolemy 'Αλνιων; Lat. *Albion*, Pliny 4, 16 [30], 102). The name is perhaps Celtic but the Romans connected it with *albus*, white, in reference to the chalk-cliffs of Dover, and A. Holder (*Alt-Keltischer Sprachschatz*, 1896) translates it *Weissland*, "white-land." The early writer (6th century B.C.) whose *Periplus* is translated by Avienus (end of 4th century A.D.) does not use the name Britannia; he speaks of νῆσος Ἰέρων καὶ Ἀλβιώνων ("island of the Ierni and the Albiones"). So Pytheas of Massilia (4th century B.C.) speaks of Ἀλβιον and Ἰέρων.

ALBION, a city of Calhoun county, Michigan, U.S.A., on the Kalamazoo river, 18 m. W. of Jackson. It is on the Michigan Central and the New York Central railways, and is connected by trolley with cities as far north as Grand Rapids and Owosso. The population was 8,354 in 1920 and was 8,324 in 1930 by the Federal census. It has 16 factories. On a commanding site in the east part of the city is Albion college (Methodist Episcopal; co-educational), which had an enrolment of 765 students in 1926-27. Albion was settled in 1831, incorporated as a village in 1866, and

chartered as a city in 1885. The city-manager form of government was adopted in 1915.

ALBION, a village in the north-western part of New York, U.S.A., about 10m. S. of Lake Ontario and 30m. W.N.W. of Rochester; the county-seat of Orleans county. It is served by the New York Central and an electric railway. The population was 4,878 in 1930 Federal census. Albion is an important fruit-shipping point and has fruit and vegetable canning factories. It is the centre of the Medina sandstone quarries. The Albion State training school, a reformatory for women, was established in 1890. The village was settled in 1812, incorporated in 1823, and became the county-seat in 1825.

ALBITE, a mineral of the felspar group and forming the sodic end member of the plagioclases (*q.v.*) (from the Lat. *albus*, in allusion to the white colour of its crystals). Albite crystallizes in the triclinic system and has the chemical composition $\text{NaAlSi}_3\text{O}_8$. In petrology the name is not restricted to the pure sodium compound but is arbitrarily adopted for mixtures containing up to 10% of the anorthite ($\text{CaAl}_2\text{Si}_2\text{O}_8$) molecule, with which it forms solid solutions. Albite forms an essential constituent of many acid and alkaline igneous rocks, in granite, syenite, porphyry, trachyte, etc., whilst in the crystalline schists it is not infrequent, as a metamorphic mineral.

ALBO-CARBON or **WHITE CARBON**: see NAPHTHALENE.

ALBOIN, d. 573, king of the Lombards and barbarian conqueror of northern Italy, succeeded his father Audoin about 565. The Lombards at that time occupied Noricum and Pannonia, and were engaged in constant war with the Gepidae. Alboin obtained the alliance of the Avars, and with their help destroyed the Gepidae, slew their king, Cunimund, in battle and married his daughter, Rosamund. On April 1, 568, Alboin had assembled his people with a great number of allies, among them 20,000 Saxons, to cross the Alps and form a new settlement in Italy. There appears to be no truth in the legend that the Lombards were invited to attack Italy by the Byzantine general, Narses. This was in effect a migration rather than a mere invasion. The Roman defences were overrun, Milan was occupied (Sept. 4, 569), and Pavia was invested. Lombard rule was established in northern Italy. But Alboin was murdered in 573 at the instigation of Rosamund, whom Alboin had insulted, so the story goes, by making her drink wine from her father's skull.

The authorities for the history of Alboin are Procopius, Paulus Diaconus and Agnellus (in his history of the Church of Ravenna).

See Hodgkin, *Italy and her Invaders*, vol. v.

ALBONI, MARIETTA (1823-1894), Italian opera-singer, was born at Cesena, Romagna, and studied at Bologna, where she became a pupil of Rossini. She had a magnificent contralto voice, and made her first appearance at La Scala, Milan, in 1843. In England her reputation was established by her appearance at Covent Garden in 1847, and she had brilliant success both in Europe and in the United States. She lived in Paris from 1866 onwards, and died at Ville d'Avray in 1894.

ALBORADA (*Span.*) signifies strictly a sunrise song or morning serenade akin to the French aubade (*q.v.*) but is now applied to a particular kind of instrumental music of a popular type to be heard in certain parts of Spain, the instruments employed being generally the bagpipes and side drum.

ALBORNOZ, GIL ALVAREZ DE, Spanish cardinal, was born at Cuenca early in the 14th century and died at Viterbo in 1367. He was made archbishop of Toledo in 1337 and cardinal in 1350. In 1353 Innocent VI. sent him from Avignon as legate into Italy with a mission to secure the restoration of the papal authority in the States of the Church. By 1362 he had paved the way for the return of Urban V. to Rome. As legate, Albornoz showed himself to be an astute manager of men and an effective fighter. He began by making use of Rienzi, whose release from prison at Avignon he secured. After the murder of the tribune in 1354 Albornoz pursued his task of restoring the Pope's authority by intrigue and force. A work by Albornoz on the constitution of the Church of Rome, first printed at Jesi in 1473, is now very rare.

BIBLIOGRAPHY.—See "De Vita et Rebus Gestis Aegidii Albornotii," in Sepulveda's *Opera Omnia*, vol. iv. (1780); H. J. Wurm, *Cardenal Albornoz der zweite Begründer des Kirchenstaates* (1892).

ALBRECHT, the German form of Albert (*q.v.*).

ALBRECHTSBERGER, JOHANN GEORG (1736–1809), famous Austrian musical theorist and teacher, was born at Kloster-Neuburg, and died in Vienna. He studied composition under the court organist, Mann, and became one of the most learned and skilful contrapuntists of his age. In 1772 he was appointed organist to the court of Vienna, and in 1792 *Kapellmeister* of St. Stephen's cathedral. His fame attracted a large number of pupils, among whom were Beethoven, Hummel and Moscheles. His compositions, consisting of preludes, fugues and sonatas for the piano and organ, string quartets, etc., are of small importance, and most of them exist only in manuscript, being preserved in the library of the Vienna *Gesellschaft der Musikfreunde*. In 1790 he published at Leipzig his *Gründliche Anweisung zur Komposition*. A collection of his writings on harmony, in three volumes, was published under the care of his pupil Ignaz von Seyfried (1776–1841) in 1826 (English version 1855).

ALBRET. The lordship (seigneurie) of Albret (Labrit, Lebrét), situated in the Landes, gave its name to a powerful French family. Arnaud Amanieu, lord of Albret, helped to take Guienne from the English. His son Charles became constable of France, and was killed at the battle of Agincourt in 1415. Alain the Great, lord of Albret (d. 1522), wished to marry Anne of Brittany, and to that end fought against Charles VIII.; but on the betrothal of Anne to Maximilian of Austria, he surrendered Nantes to the French in 1486.

John of Albret, son of Alain, became king of Navarre by his marriage with Catherine of Foix. Their son Henry, king of Navarre, was created duke of Albret and peer of France in 1550. By his wife Margaret, sister of the French king, Francis I., he had a daughter, Jeanne d'Albret, queen of Navarre, who married Anthony de Bourbon, duke of Vendôme, and became the mother of Henry IV., king of France.

ALBUERA, LA (or **ALBUHERA**), a small village of Spain, in the province of Badajoz, 13m. S.E. of the town of that name, insignificant in itself but celebrated on account of the victory gained there on May 16, 1811, by the British, Portuguese and Spaniards, under Marshal Beresford, over the French army commanded by Marshal Soult.

After Portugal had been cleared of the French invading army under Masséna, Wellington sought to secure his position by recovering the frontier fortresses. He himself invested Almeida while Beresford was sent with 10,000 Spaniards, 9,000 Portuguese and 9,000 British only, to lay siege to Badajoz. But the latter was hardly in position before Soult moved upon him from the south with 27,000 veterans. Beresford took up a covering position at Albuera, astride the road to Badajoz, but his dispositions were faulty and Masséna, feinting at a direct thrust down the road, made a concealed manoeuvre round the allied right flank. Here the Spanish were cut to pieces or dispersed, a British brigade, hurrying to their aid, was annihilated by the French cavalry, and only a thin line of 1,800 British "red-coats" strung out on a ridge intervened between the French mass of manoeuvre and complete victory. Thin as it was, being a line, it overlapped the front of the massed French columns, and thus gained full value from its fire. For half an hour both sides poured a heavy musketry fire into each other's ranks at point-blank range, and then the nerves of the French snapped under the exorbitant toll, and their columns rolled back down the slopes, gaining momentum as they went until their retirement became a rout. The French losses were some 8,000, and those of the British 4,000 in all, while the Spaniards lost 1,400. Strategically, Beresford's decision to fight was a mistake, for the siege had already been abandoned on Soult's approach; it exposed him to disaster when isolated, and even as it was the losses grievously impaired Wellington's strength. But morally, it had a vital influence on subsequent encounters.

ALBUFERA DE VALENCIA, lagoon, 7m. south of Valencia in Spain, about 12m. long, 14m. broad and 12ft. deep

(max.), with a narrow outlet to sea under control. It is crown property and rich in fish and wild fowl, and rice is grown around it. Napoleon made Marshal Suchet duke of Albufera (1812) after the conquest of Valencia. After the battle of Vittoria (1813) he lost the domain but kept the title. Later, the Spanish nation gave the revenues of Albufera to the duke of Wellington.

ALBULA PASS, the principal route from the north to the Upper Engadine in the Grisons. It was used in the 13th century and a carriage road (highest point, 7,595ft.) was made across it in 1865, but for a long time it was not as much used as the easier and more direct Julier pass (7,504ft.). The opening of the railway in 1903, however, vastly increased its importance. Starting from Coire the railway follows the Rhine to Reichenau (6¼m.), and then the Hinter Rhine to Thusis (10½m.). It then runs through the grand Schyn gorge (cut by the Albula torrent) to Tiefenkastell (7½m.), where it leaves the Julier road on the right (south), and continues to follow the course of the Albula past Filisur and Bergün (12½m.) to the mouth (5,879ft.) of the tunnel (3¾m. in length; highest point, 5,987ft.) which has been pierced below the pass. The railway descends through the Bevers glen to Bevers (2½m.), in the Upper Engadine, about 5m. below St. Moritz, which is 56m. from Coire by this route.

AFTER "DICTIONNAIRE DES ANTIQUITÉS GREQUES ET ROMAINES"

AN ALBUM FOUND IN POMPEII, ITALY, AT THE ENTRANCE OF ONE OF THE STREETS LEADING TO THE FORUM

the roll in which a bishop inscribes the names of his clergy. In law, the word is the equivalent of *maillles blanches*, for rent paid in silver ("white") money.

ALBUMAZAR or properly **ABU-MAASCHOR** (805–885), Arab astronomer, was born at Balkh, flourished at Baghdad and died at Wasid in Central Asia. His principal works were translated into Latin: *De Magnis Conjunctionibus* (Augsburg, 1489); *Introductorium in Astronomiam* (Venice, 1506) and *Flores Astrologici* (Augsburg, 1488). He maintained in the first that the world, created when the seven planets were in conjunction in the first degree of Aries, will come to an end at a like conjunction in the last degree of Pisces. Albumazar's name is used for the subject of *L'Astrologo* by Gian Battista del Porta (1606), a play which was adapted in *Albumazar* by John Tomkis, played before James I. in 1614, revived by Dryden in 1748.

See *Biog. Universelle* (Jourdain); Lalande, *Bibliographie Astronomique*; Poggendorff, *Biog. literarisches Handwörterbuch*; Houzeau, *Bibl. Astronomique*.

ALBUMIN or **ALBUMEN** was originally used to denote the main constituent of the white of eggs. It was then applied to any of the substances of similar properties and composition found in vegetable and animal cells and also in milk and eggs. These substances are now known as proteins, and the albumins are regarded as a particular group of this very complex class. The special properties of the albumins are described in the article on proteins (*q.v.*).

ALBUMINOIDS: see **PROTEINS**.

ALBUMINS: see **PROTEINS**.

ALBUMINURIA, a general name for conditions in which the urine contains proteid matter. Normally the secreting and conducting parts of the urinary system hold back in the blood, out of which the urine is formed, all protein. But when the kidney is diseased (see **KIDNEY, DISEASES OF**), whether primarily or secondarily, its efficiency as a filter is impaired and albumin

appears in the urine. As a rule this is in the form of serum-albumin and serum-globulin, but occasionally it occurs as albumoses (albumosuria). Under certain conditions the urine may contain albumin in individuals apparently quite healthy (physiological albuminuria). The most common cause is strenuous muscular exertion, but in some individuals there occurs, intermittently, an albuminuria (paroxysmal albuminuria) which appears without obvious cause beyond perhaps a trivial exposure to cold. Cases in which the urine contains blood (haematuria) or its colouring matter (haemoglobinuria), both of which are proteins, are not included under albuminuria. Owing to its importance as a symptom, its existence in a candidate for life assurance is usually regarded by the company as a complete bar to acceptance of the risk. In inflammatory conditions of the bladder and urethra, albumin is often present in the urine, in a sense as an accident.

(W. S. L.-B.)

ALBUQUERQUE, ALPHONSO D' (in old Portuguese *AFFONSO D'ALBOQUERQUE*) (1453-1515), surnamed **THE GREAT**, and **THE PORTUGUESE MARS**, was born in 1453 at Alexandria, near Lisbon, and educated at the court of Alphonso V. In 1503 he set out on his first expedition to the East. He sailed round the Cape of Good Hope to India, where he obtained from the king of Cochin permission to build a Portuguese fort. He returned home in July 1504, and King Emmanuel gave him the command of a squadron of five vessels in the fleet of 16 which sailed for India in 1506 under Tristan da Cunha. After a series of attacks on the Arab cities on the east coast of Africa, Albuquerque separated from Da Cunha, and captured (Sept. 1507) the island of Ormuz, in the Persian Gulf, which was then one of the chief centres of commerce in the East. He was unable long to maintain his position.

With his squadron increased by three vessels, he reached the Malabar coast at the close of 1508, and produced a commission from the king empowering him to supersede the governor Francisco de Almeida. The governor's reply was imprisonment, from which Albuquerque was only released on the arrival of the grand marshal of Portugal with a large fleet. An unsuccessful attack upon Calicut in Jan. 1510 was immediately followed by the investment and capture of Goa. Albuquerque abandoned the town in August, to return with the reinforcements in November, when he obtained undisputed possession. He next directed his forces against Malacca, which he subdued after a severe struggle. He remained in the town nearly a year to consolidate the position. In 1512 he sailed for the coast of Malabar. On the voyage, Albuquerque's vessel, the "Flor de la Mar," which carried the treasure he had amassed in his conquests, was wrecked, and he himself barely escaped with his life. In September of the same year he arrived at Goa, where he quickly suppressed a serious revolt headed by Idalcán.

Albuquerque had been for some time under orders from the home Government to undertake an expedition to the Red Sea, in order to secure that channel of communication exclusively to Portugal. He accordingly laid siege to Aden in 1513, but was repulsed; and a voyage into the Red Sea, the first ever made by a European fleet, led to no substantial results. His last success was the recapture in 1515 of the island of Ormuz, which remained in the possession of the Portuguese until 1622. Albuquerque had several enemies at the Portuguese court, and on his return from Ormuz, at the entrance of the harbour of Goa, he met a vessel from Europe bearing despatches announcing that he was superseded by his personal enemy, Soarez. He died at sea on Dec. 16, 1515. Before his death he wrote a letter to the king in dignified and affecting terms, vindicating his conduct and claiming for his son the honours and rewards due to himself.

His body was buried at Goa, and it is, perhaps, the most convincing proof possible of the justice of his administration that, many years after, Mussulmans and Hindus used to go to his tomb to invoke protection against the injustice of his successors. His natural son Affonso published a selection from his father's papers under the title *Commentarios do Grande Affonso d'Albuquerque*.

BIBLIOGRAPHY.—See the *Cartas de Albuquerque*, published by the

Lisbon Academy (vol. i., 1884); also Morse Stephens's *Life of Albuquerque* in the "Rulers of India" series; an article in the *Boletim* of the Lisbon Geographical Society (Jan. to June 1902) on "O antigo Imperialismo português, etc.," has especial reference to Albuquerque.

ALBUQUERQUE, MATHIAS DE (d. 1647), Portuguese general, was governor of Pernambuco in 1624 and, after the Dutch captured Bahia, governor-general of North Brazil. As governor in Pernambuco again, in 1629, he had to meet the Dutch invasion of that province, and in 1630 was forced to surrender Olinda and the forts of the Recife. Sent back to Portugal in disgrace in 1635, he took part, later, in the Portuguese War of Liberation, defeating the Spaniards under Mölingen at Montijo, on May 26, 1644, and thereby earning the title of Count of Allegrete. He died at Lisbon June 9, 1647.

ALBUQUERQUE, the largest city of New Mexico, U.S.A., near the centre of the state, in a fertile strip of land on the east bank of the Rio Grande; on the National Old Trails road, and at the junction of two main lines of the Santa Fé railway system. It is the county-seat of Bernalillo county. Between 1900 and 1920 the population increased from 6,238 to 15,157; in 1930 it was 26,570, Federal census.

The city lies at an altitude of 4,954ft., and the average annual precipitation is less than 8in. The bracing climate and the large proportion of sunshiny days have given it an established reputation as a health resort, and it has several private sanatoria for the treatment of tuberculosis.

Albuquerque is the commercial capital of an irrigated farming district, of the sheep and cattle business, and the lumber industry of the state. It ships large quantities of wool. Its industrial establishments include saw and lumber mills, a sash factory, foundry and machine shops, woollen mills, brick yards, railway repair shops, and plants making cement blocks, harness and farm implements. In 1927 there were 28 factories, with an output valued at \$6,343,854, which was 32% of the valuation for the entire state. On the plateau, about a mile east of the business district, stands the University of New Mexico (opened in 1892). In 1926-27 it had an enrolment of 638 and a library of 65,000 volumes, including a collection on the history of the state. An adaptation of the Pueblo style of architecture has been used in the university buildings and in many public buildings of the city.

Albuquerque is in the heart of the Pueblo Indian country, and is an important market for Indian blankets. There is a federal industrial training school for Indian boys and girls. Within easy motoring distance are the pueblos of San Felipe, which has a church built by Fray Cristobal de Quinones (d. 1609); of Isleta and Santo Domingo, where fine ceremonial dances are still performed; of picturesque Laguna, with its interesting mission church; and of Acoma, perched on a precipitous mesa 357ft. high, which was already very old when Fray Marcos arrived in 1539.

The "old town," which lies along the river bank, was founded in 1701 by Gov. Pedro Rodriguez y Cubero, and named by him after the Duke of Albuquerque, a viceroy of New Spain. The Duke ordered the name to be changed to San Felipe de Albuquerque, as a compliment to the reigning king. With the passage of time it became reduced to one word, and that word lost one of its r's. The mission church of San Felipe de Neri (1735) is still standing, and the entire district keeps its old Spanish character. It was an important centre in the Spanish and the Mexican occupations. During the Civil War it was occupied by Confederate troops (Feb. 1862) under Gen. Henry Hopkins Sibley, who soon afterwards advanced into northern New Mexico. In his retreat into Texas he made a stand here, on April 8, 1862, against a detachment of Union troops commanded by Colonel R. S. Canby. The modern city was founded in 1879; the railway reached it in 1880; by 1890 it had a population of 3,785. A commissioner-manager form of government was adopted in 1917.

ALBURNUM (sapwood), the outermost and youngest part of the wood of a tree, through which the upward water current mainly passes. It is distinguished from the harder inner and older wood, the duramen or heart-wood.

ALBURY, a small country town of rising importance in Goulburn county, New South Wales. Situated at an elevation of 542ft. on the right (north) bank of the river Murray (*q.v.*),

approximately 1,470m. from its mouth, Albury marks the head of possible navigation (July–December) on this stream, though at present river steamers normally ply only as far as Echuca. Its position, again, on the western flank of the eastern highlands, not far from the point of debouchment of the Murray, and in the general line of connection between Melbourne and Sydney, constitutes Albury a crossing-place of some importance. As a fording point it has figured in the history of Australian exploration. In 1883 the Victoria and New South Wales railway systems were connected at this point, and Albury is now a bridge town on the main line linking Victoria and New South Wales (Albury–Sydney c. 350m., Albury–Melbourne c. 190 m.), and also the eastern and western portions of the continent (Transcontinental line, Fremantle and Perth–Brisbane). The river is crossed by means of an iron bridge from Wodonga on the Victorian side, and here also is a break of gauge (Victorian system: 5' 3"; N.S.W.: 4' 8½"). A little above Albury is the confluence of the Murray with its tributary the Mitta Mitta. Albury, therefore, figures in the now historic River Murray Agreement (1914), and it will acquire further considerable importance as a result of the execution of the schemes under that agreement, notably that of the Hume reservoir. Albury, which has a mean annual temp. of 60.7°; mean annual rainfall: 27.65in., of which 18.9in. falls in the seven months, April–October, is the centre and virtual capital of the eastern Riverina, a rich agricultural and pastoral district producing wheat, fruit and sheep. Albury became a municipality in 1859, and has shown a steady rise in population (1891, 5,447; 1921, 7,752; 1924, 8,310).

ALCAEUS or **ALKAIOS** (c. 600 B.C.), Greek poet, holds second place in the Alexandrian lyric canon. He was a contemporary of Sappho, and a member of one of the noble families of Mitylene.

In the war against the Athenians (606), he fled from battle with the loss of his shield. His political enemies drove him into exile, but towards the end of his life he is said to have been pardoned by Pittacus. His poems, which were written in the Aeolic dialect, included hymns; political poems (*stasiōtika*), in which he abused the tyrants, his political enemies; love-songs; and drinking-songs. He seems to have invented the Alcaic metre, and was regarded as a model by Horace.

See Bergk, *Poetae Lyrici Graeci* (1882); also *The Songs of Alcaeus*, by J. Easby-Smith (Washington, 1901); Plehn, *Lesbiacorum Liber* (1826); Flach, *Geschichte der griechischen Lyrik* (1883–84); Farnell, *Greek Lyric Poets* (1891). New fragments edited by J. M. Edmonds (1909). See also Edgar Lobel, *Ἀλκαίου Μέλῃ, the Fragments of the Lyric Poems of Alcaeus* (Oxford, 1928).

ALCAICS, the name of several lyric verses, from Alcaeus of Lesbos, their supposed inventor. They comprise:

(1) Alcaic hendecasyllable: ♀-♂-♂-♂-♂-♂-♂-♂-♂-♂-♂

Examples: Latin, "odi profanum volgus et arceo."

English imitation, "O mighty-mouthed inventor of harmonies."

(2) Alcaic decasyllable: ♀-♂-♂-♂-♂-♂-♂-♂-♂-♂

Examples: Latin, "virginibus puerisque canto."

English imitation, "Milton, a name to resound for ages."

(3) Alcaic enneasyllable: ♀-♂-♂-♂-♂-♂-♂-♂-♂

Examples: Latin, "audita Musarum sacerdos."

English imitation, "God-gifted organ-voice of England."

The Alcaic stanza consists of (1) twice repeated, followed by (3) and then (2), once each. It was a great favourite, not only of its inventor, but of Horace, who made some very slight modifications to adapt it to Latin. In modern languages it has been imitated by Tennyson (from whom the above English lines are taken) and occasionally by poets in other languages, but never with much success.

The manner in which the lines should be divided into feet is, in this as in all "Aeolic" metres, a highly controversial point.

ALCAIDE, a Spanish title meaning the governor of a fortress (Arabic *al-quā'id*).

ALCALÁ (Moorish *al kala*, the "Fortress" or "Castle"), the name of thirteen Spanish towns, all founded or named by the Moors. Alcalá de Henares, pop. (1920) 11,142, is separately described on account of its historical importance. Alcalá la Real

(17,267), a picturesque town with a fine abbey, is situated in the mountainous south-west part of Jaén. Its distinctive name *la Real*, "the Royal," was conferred in memory of its capture by Alphonso XI. of Leon in 1340. In 1810 the French under Count Sebastiani here defeated the Spaniards. Alcalá de los Gazules (9,959), on the river Barbate, in the province of Cadiz, trades in cork and agricultural produce. Alcalá de Guadaira (11,038), on the river Guadaira, near Seville, is popularly called Alcalá de los Panaderos, or "Alcalá of the Bakers," because it supplies Seville with large quantities of bread; it also manufactures for export the best "Seville oil."

ALCALA DE HENARES, Spain, 17m. E.N.E. of Madrid, on the river Henares. Pop. (1920) 11,142. Alcala de Henares contains a military academy. The town has been identified with the Roman *Complutum*, destroyed about 1000, and rebuilt by the Moors in 1083. Later its university, founded by Cardinal Jimenes de Cisneros in 1510, was second only to that of Salamanca. Here the famous *Complutensian Polyglot Bible* was prepared from 1514 to 1517. The college of San Ildefonso completed in 1583, was the chief university building. Its modernized Gothic church, the Colegiata, contains the 16th century marble monument of Jimenes (d. 1517) and a fine reredos.

On the removal of the university to Madrid in 1836 the town declined, and the university buildings became archives of state departments and of the Inquisition. One of the principal libraries is the former palace of the archbishops of Toledo.

BIBLIOGRAPHY.—H. Florez and others, "Annales Complutenses" and "Chronicon Complutense" in *España Sagrada* (1754–1879); Galo Sanchez, *Fueros Castellanos de Soria y Alcalá de Henares* (1919).

ALCALDE, the title in Spanish for officials of somewhat varied functions in which, however, there is always a judicial element. *Alcalde de corte* was a judge of the palace court, having jurisdiction in and about the residence of the king. But the title is now exclusively used for the mayor of a town or village who discharges the functions of a justice of the peace. The title of *alcalde* must be carefully distinguished from *alcaide* (*q.v.*) which means the governor of a fortress.

ALCAMENES, a Greek sculptor of Lemnos and Athens. He was a younger contemporary of Pheidias and noted for the delicacy and finish of his works, among which a Hephaestus and an Aphrodite "of the Gardens" were conspicuous. Pausanias says (v. 10, 8) that he was the author of one of the pediments of the temple of Zeus at Olympia (see GREEK ART), but this seems a chronological and stylistic impossibility. At Pergamum there was discovered in 1903 a copy of the head of the Hermes "Propylaeus" of Alcamenes (*Athenische Mittheilungen*, 1904, p. 180). It is safer, however, to judge him by the sculptural decoration of the Parthenon, in which he must almost certainly have taken a share under the direction of Pheidias.

ALCAMO, province of Trapani, Sicily, 24m. W.S.W. of Palermo direct (51½m. by rail). Population (1921) 63,051. The Saracenic chief Al-Kamuk erected the castle (A.D. 828), considerably altered since. Frederick II. removed the site lower down (1233). The surrounding district is very fertile.

ALCANTARA, a small seaport of Brazil, in the State of Maranhão, on the west shore of the bay of São Marcos, 16m. from the city of Maranhão by water. It has a fairly good harbour, and excellent cotton and rice are grown in the vicinity and shipped from the port.

ALCÁNTARA, western Spain, province of Cáceres, on a rocky height on the left bank of the river Tagus, 7m. from the Portuguese frontier. Pop. (1920) 3,954. Alcántara (in Arab. "the bridge") owes its name to the magnificent Roman bridge which spans the Tagus on the northwest, built about A.D. 105, in honour of the emperor Trajan and at the cost of eleven Lusitanian communities. A small temple, dedicated to Trajan and other deified emperors, adjoined the bridge on the left bank. Though it has been identified with Norba Caesarea and with Interamnium, it is doubtful whether there was a Roman town here. It became famous about 1215 as the stronghold of the knights of Alcántara, many of whose grand masters lie buried in the 13th-century Gothic church.

ALCAVALA, a duty charged in Spain and its colonies until the invasion of Napoleon (from Arab. *al-quabalah*, "tax," *quabala*, "to receive"; cf. Fr. *gabelle*). Originally imposed in 1341 by Alphonso XI. to secure freedom from the Moors, it was an *ad valorem* tax of 10%, increased afterwards to 14%, on the selling price of all commodities, whether raw or manufactured, and chargeable as often as they were sold or exchanged. This was a monstrous imposition which subjected every farmer, manufacturer, merchant and shopkeeper to the continual visits and examination of the tax-gatherers, whose number was necessarily very great.

ALCAZAR, B. DEL (1530–1606), Spanish poet, was born at Seville. He served under the Marqués de Santa Cruz and afterwards in the households of the Duque de Alcala and of the Conde de Gelves. Alcazar belonged to the Italianate school and modelled himself on Martial. The grace and cynicism of Baltasar del Alcazar are manifested in his *Poesias* (ed. F. R. Marin, 1910).

ALCÁZAR DE SAN JUAN or **ALCÁZAR**, Spain, province of Ciudad Real, and an important railway junction, where the lines to the east and south-east diverge from the main line to Andalusia. Pop. (1920) 16,117. Alcázar trades in wine and manufactures soap, gunpowder, chocolate and inlaid daggers. It is sometimes identified with the Roman *Alce*, captured by Tiberius Sempronius Gracchus in 180 B.C. It derives its name from its mediaeval Moorish castle (*al-kasr*), afterwards garrisoned by the knights of St. John. The entire district is associated with Cervantes and with the action of *Don Quixote* (El Toboso, 12m. E.N.E.; Argamasilla de Alba, 22m. S.E.). Local antiquaries even identify the knight with Don Rodrigo de Pacheco, whose portrait adorns the parish church.

ALCESTER, FREDERICK BEAUCHAMP PAGET SEYMOUR, BARON (1821–95), British admiral, was born April 12, 1821. Entering the navy in 1834, he served in the Mediterranean and the Pacific, was for three years flag-lieutenant to his uncle Sir George Seymour, and was promoted to be commander in 1847. He had a distinguished naval record and held a series of high commands. In 1880–83 he was commander-in-chief of the fleet in the Mediterranean, and in 1880 had also the chief command of the European squadron sent to the coast of Albania as a demonstration to the Porte to cede Dulcigno to Montenegro. In July 1882 Admiral Seymour commanded at the bombardment of Alexandria and in the subsequent operations on the coast of Egypt, for which service he was raised to the peerage, received a parliamentary grant of £25,000, the freedom of the City of London and a sword of honour. He retired from the service in 1886, and died in London, March 30, 1895.

ALCESTER (aul'stūr), a market-town, Warwickshire, 16m. W.S.W. of Warwick on the Great Western, Southern, and London, Midland and Scottish railways. Population of rural district (1931) 11,233. It is situated at the junction of the small stream Alne with the Arrow, a northern tributary of the Avon.

The name (Alnecestre, Alyncester) signifies "the camp on the Alne." A small Romano-British town or village was situated here on the road which ran from Derby to join the Fosse Way near Cirencester. Pavements, potsherds, coins and burials have been found, but nothing to indicate an important station. No written document relating to Alcester exists before the reign of Henry I. when it seems to have been a royal borough, but the title of borough soon lapsed. In the reign of Henry III. a moiety of the manor was purchased by Sir Walter Beauchamp, who granted a charter establishing a Tuesday market for corn, cattle and all kinds of merchandise, and also obtained grants of fairs. In 1444 Sir John Beauchamp purchased the remaining moiety of the manor, and was granted an additional fair. From this date the Beauchamps were lords of the whole manor until it passed by female descent to the Grevilles in the reign of Henry VIII. In 1140 a Benedictine monastery was founded here by Ralph Boteler of Oversley, and received the name of the Church of Our Lady of the Isle, owing to its insulation by a moat meeting the River Arrow. The monastery was suppressed among the smaller houses in 1536. Traces of the moat and the foundations are still to be seen in Priory Close. The ancient fairs sur-

vived to the end of the 19th century. The church of St. Nicholas was rebuilt in 1734.

The manufacture of needles, which employed nearly 1,000 hands in 1830, is now unimportant, having been absorbed into the centre of the industry at Redditch. There are implement and cycle works, metal glazing and polishing being a special feature.

ALCESTIS, in Greek legend, the wife of Admetus (*q.v.*).

ALCHEMY. In the narrow sense of the word, alchemy is the pretended art of making gold and silver, or transmuting the base metals into the noble ones. The idea of such transmutation probably arose among the Alexandrian Greeks in the early centuries of the Christian era; thence it passed to the Arabs, by whom it was transmitted to western Europe, and its realization was a leading aim of chemical workers down to the time of Paracelsus and even later. Alchemy in its wider and truer significance stands for the chemistry of the middle ages. The idea of transmutation, in the country of its origin, had a philosophical basis, and was linked up with the Greek theories of matter there current; thus, by supplying a central philosophical principle, it to some extent unified and focused chemical effort, which previously, so far as it existed at all, had been expended on acquiring empirical acquaintance with a mass of disconnected technical processes. Alchemy in this sense is merely an early phase of the development of systematic chemistry; in Liebig's words, it was "never at any time anything different from chemistry."

Regarding the derivation of the word, there are two main views which agree in holding that it has an Arabic descent, the prefix *al* being the Arabic article. But according to one, the second part of the word comes from the Greek *χυμela*, pouring, infusion, used in connection with the study of the juices of plants, and thence extended to chemical manipulations in general; this derivation accounts for the old-fashioned spellings "chymist" and "chymistry." The other view traces it to *khem* or *khamé*, hieroglyph *khmi*, which denotes black earth as opposed to barren sand, and occurs in Plutarch as *χυμela*; on this derivation alchemy is explained as meaning the "Egyptian art." The first occurrence of the word is said to be in a treatise of Julius Firmicus, an astrological writer of the 4th century, but the prefix *al* there must be the addition of a later copyist. In English, *Piers Plowman* (1362) contains the phrase "experimentis of alconomye," with variants "alkenemye" and "alknamye." The prefix *al* begins to be dropped about the middle of the 16th century.

Origins of Alchemy.—Numerous legends cluster round the origin of alchemy. According to one story, it was founded by the Egyptian god Hermes (Thoth), the reputed inventor of the arts and sciences; after him later alchemists called their work the "hermetic art," and the seal of Hermes, which they placed upon their vessels, is the origin of the common phrase "hermetically sealed." Another legend asserts that the fallen angels taught the arts to the women they married, their instruction being recorded in a book called *Chemā*. A similar story appears in the Book of Enoch, and Tertullian has much to say about the wicked angels who revealed to men the knowledge of gold and silver, of lustrous stones and of the power of herbs, and who introduced the arts of astrology and magic upon the earth. Another legend, to be found in Arabic sources, asserts that alchemy was revealed by God to Moses and Aaron. But there is some evidence that, in accordance with the strong and constant tradition among the alchemists, the idea of transmutation did originate in Egypt with the Greeks of Alexandria. In the Leyden museum there are a number of papyri which were found in a tomb at Thebes, written probably in the 3rd century A.D., though their matter is older. Some are in Greek and demotic, and one, of peculiar interest from the chemical point of view, gives a number of receipts, in Greek, which show a considerable knowledge in the manipulation of base metals to form alloys which simulate gold, and are intended to be used as a workshop manual in the manufacture of imitation jewellery. Possibly this is one of the books about gold and silver of which Diocletian decreed the destruction about A.D. 290. It has been suggested by M. P. E. Berthelot that the workers in these processes, which were a monopoly of the priestly caste and were

kept strictly secret, though fully aware that their products were not truly gold, were in time led by their success in deceiving the public to deceive themselves also, and to come to believe that they actually had the power of making gold from substances which were not gold. Philosophical sanction and explanation of this belief was then found by bringing it into relation with the theory of the *prima materia*, which was identical in all bodies but received its actual form by the adjunction of qualities expressed by the Aristotelian elements—earth, air, fire and water. Some support for this view is gained from study of the alchemical writings of the period. Thus, in the treatise known as *Physica et Mystica* and falsely ascribed to Democritus (such false attributions are a constant feature of the literature of alchemy), various receipts are given for colouring and gilding metals, but the conception of transmutation does not occur. This treatise was probably composed at a date not very different from that of the Leiden papyrus. Later, however, as in the *Commentary* on this work written by Synesius to Dioscorus, priest of Serapis at Alexandria, which probably dates from the end of the 4th century, a changed attitude becomes apparent; the more practical parts of the receipts are obscured or omitted, and the processes for preparing alloys and colouring metals, described in the older treatise, are by a mystical interpretation represented as resulting in real transmutation.

But while there are thus some grounds for supposing that the idea of transmutation grew out of the practical receipts of Alexandrian Egypt, the alchemy which embraced it as a leading principle was also much affected by Eastern influences such as magic and astrology. The earliest Greek alchemical writings abound in references to Oriental authorities and traditions. Thus the pseudo-Democritus, who was the reputed author of the *Physica et Mystica*, which itself concludes each of its receipts with a magical formula, was believed to have travelled in Chaldaea, and to have had as his master Ostanos the Mede, a name mentioned several times in the Leyden papyrus, and often by early Christian writers such as Tertullian, St. Cyprian and St. Augustine. The practices of the Persian adepts also are appealed to in the writings of the pseudo-Democritus, and of Zosimus and Synesius. The philosopher's egg, as a symbol of creation, is both Egyptian and Babylonian. In the Greek alchemists it appears as the symbol at once of the art and of the universe, enclosing within itself the four elements. The conception of man, the microcosm, containing in himself all the parts of the universe or macrocosm, is also Babylonian, as again probably is the famous identification of the metals with the planets. Even in the Leyden papyrus the astronomical symbols for the sun and moon are used to denote gold and silver, and in the *Meteorologica* of Olympiodorus lead is attributed to Saturn, iron to Mars, copper to Venus, tin to Hermes (Mercury) and electrum to Jupiter. Similar systems of symbols, but elaborated to include compounds, appear in Greek mss. of the 10th century, preserved in the library of St. Mark's at Venice. Subsequently electrum (an alloy of gold and silver) disappeared as a specific metal, and tin was ascribed to Jupiter instead, the sign of mercury becoming common to the metal and the planet.

Literature of Alchemy.—A considerable body of Greek chemical writings is contained in mss. belonging to the various great libraries of Europe, the oldest being that at St. Mark's, just mentioned. The contents of these mss. are all of similar composition, and in Berthelot's opinion represent a collection of treatises made at Constantinople in the 8th or 9th century. The treatises are nearly all anterior to the 7th century, and most appear to belong to the 3rd and 4th centuries; some are the work of authentic authors like Zosimus and Synesius, while others, such as profess to be written by Moses, Democritus, Ostanos, etc., are of clearly fictitious authorship. Some of the same names and the same works can be identified in the lists of the *Kitāb-al-Fihrist* (written by al-Nadim towards the end of the 10th century). But the Arabs did not acquire their knowledge of this literature at first hand. The earliest Hellenic culture in the East was Syrian, and the Arabs made their first acquaintance with Greek chemistry, as with Greek philosophy, mathematics, medicine, etc., by the intermediary of Syriac translations. (See ARABIAN PHILOSOPHY and SYRIAC LITERATURE.) Examples of such translations are

preserved in mss. at the British Museum, partly written in Syriac, partly in Arabic with Syriac characters. In Berthelot's opinion, the Syriac portion represents a compilation of receipts and processes undertaken in the Syrian school of medicine at Bagdad under the Abbasids in the 9th or 10th century, and to a large extent constituted by the earlier translations made by Sergius of Resaena in the 6th century. They contain, under the title *Doctrinae of Democritus*, a fairly methodical treatise in ten books comprising the *Argyropoeia* and *Chrysopoeia* of the pseudo-Democritus, with many receipts for colouring metals, making artificial precious stones, effecting the *diplosis* or doubling of metals, etc. They give illustrations of the apparatus employed, and their close relationship to the Greek is attested by the frequent occurrence of Greek words and the fact that the signs and symbols of the Greek alchemists appear almost unchanged. The other portion seems of somewhat later date. Another Syriac ms., in the library of Cambridge university, contains a translation of a work by Zosimus which is so far unknown in the original Greek. Berthelot gives reproductions of the British Museum mss. in vol. ii. of *La Chimie au moyen âge*.

Several alchemical treatises, written in Arabic, exist in manuscript in the National Library at Paris and in the library of the University of Leyden, and have been reproduced by Berthelot, with translations, in vol. iii. of *La Chimie au moyen âge*. They fall into two groups: those in one are largely composed of compilations from Greek sources, while those in the other have rather the character of original compositions. Of the first group the most interesting and possibly the oldest is the *Book of Crates*; it is remarkable for containing some of the signs used for the metals by the Greek alchemists, and for giving figures of four pieces of apparatus which closely resemble those depicted in Greek mss., the former being never, and the latter rarely, found in other Arabic mss. Its concluding words suggest that its production was due to Khalid ben Yezid (died in 708), who was a pupil of the Syrian monk Marianus, and according to the *Kitāb-al-Fihrist* was the first Muslim writer on alchemy. The second group consists of a number of treatises professing to be written by Jaber, celebrated in Latin alchemy as Geber (*q.v.*). Internal evidence suggests that they are not all from the same hand or of the same date, but probably they are not earlier than the 9th nor later than the 12th century. The Arabic chroniclers record the names of many other writers on alchemy, among the most famous being Rhazes and Avicenna.

But the further development of alchemy took place in the West rather than in the East. With the spread of their empire to Spain the Arabs took with them their knowledge of Greek medicine and science, including alchemy, and thence it passed to the nations of western Europe, through the medium of Latin translations which began about the 11th century. The *Liber de compositione alchemiae*, which professes to be by Morienus—perhaps the same as the Marianus who was the teacher of Khalid—was translated by Robertus Castrensis, who states that he finished the work in 1182. The earlier translations, such as the *Turba Philosophorum* and other works printed in collections like the *Artis auriferae quam chemiam vocant* (1572), *Theatrum chemicum* (1602), and J. J. Manget's *Bibliotheca chemica curiosa* (1702), are confused productions, written in an allegorical style, but full of phrases and even pages taken literally from the Greek alchemists, and citing by name various authorities of Greek alchemy. They were followed by treatises of a different character, clearer in matter, more systematic in arrangement, and reflecting the methods of the scholastic logic; these are farther from the Greek tradition, for although they contain sufficient traces of their ultimate Greek ancestry, their authors do not know the Greeks as masters and cite no Greek names. So far as they are Latin versions of Arabico-Greek treatises, they must have been much remodelled in the course of translation; but there is reason to suppose that many of them, even when pretending to be translations, are really original compositions. It is curious that although we possess a certain number of works on alchemy written in Arabic, and also many Latin treatises that profess to be translated from Arabic, yet in no case is the existence known of both the Arabic and the Latin version. The Arabic works of Jaber, as contained in mss. at Paris and Leyden,

are quite dissimilar from the Latin works attributed to Geber, and show few if any traces of the positive chemical knowledge, as of nitric acid (*aqua dissolutiva* or *fortis*) or of the mixture of nitric and hydrochloric acids known as *aqua regis* or *regia*, that appears in the latter. The treatises attributed to Geber, in fact, appear to be original works composed not earlier than the 13th century and fathered on Jaber in order to enhance their authority.¹ If this view be accepted, an entirely new light is thrown on the achievements of the Arabs in the history of chemistry, for the chemical knowledge attributed to the Arabs has been so attributed largely on the basis of the contents of the Latin Geber, regarded as a translation from the Arabic Jaber. If, then, those contents do not represent the knowledge of Jaber, and if the contents of other Latin translations, which there is reason to believe are really made from the Arabic, show little, if any, advance on the knowledge of the Alexandrian Greeks, evidently the part played by the Arabs must be less, and that of the Westerns greater, than is generally supposed.

The descent of alchemical doctrine can thus be traced with fair continuity for a thousand years, from the Greeks of Alexandria down to the time when Latin alchemy was firmly established in the West, and began to be written of by historical authors like Albertus Magnus, Roger Bacon and Arnoldus Villanovanus in the 13th century. But side by side with this literary transmission Berthelot insists that there was another mode of transmission, by means of the knowledge of practical receipts and processes traditional among jewellers, painters, workers in glass and pottery, and other handicraftsmen. The chemical knowledge of Egyptian metallurgists and jewellers, he holds, was early transmitted to the artisans of Rome, and was preserved throughout the dark ages in the workshops of Italy and France until about the 13th century, when it was mingled with the theories of the Greek alchemists which reached the West by way of the Arabs. Receipts given in the Leiden papyrus reappear in the *Compositiones ad Tingenda* and the *Mappae Clavicula*, both workshop receipt books, one known in an 8th-century ms. at Lucca, and the other in a 10th-century ms. in the library of Schlettstadt; and again in such works as the *De Artibus Romanorum* of Eraclius and the *Schedula Diversarum Artium* of Theophilus, belonging to the 11th or 12th century.

Theory of Transmutation.—The fundamental theory of the transmutation of metals is to be found in the Greek alchemists, although in details it was modified and elaborated by the Arabs and the Latin alchemists. Regarding all substances as being composed of one primitive matter—the *prima materia*—and as owing their specific differences to the presence of different qualities imposed upon it, the alchemist hoped, by taking away these qualities, to obtain the *prima materia* itself, and then to get from it the particular substance he desired by the addition of the appropriate qualities. The *prima materia* was early identified with mercury, not ordinary mercury, but the “mercury of the philosophers,” which was the essence or soul of mercury, freed from the four Aristotelian elements—earth, air, fire and water—or rather from the qualities which they represent. Thus the operator had to remove from ordinary mercury, earth or an earthy principle or quality, and water or a liquid principle, and to fix it by taking away air or a volatile principle. The *prima materia* thus obtained had to be treated with sulphur (or with sulphur and arsenic) to confer upon it the desired qualities that were missing. This sulphur again was not ordinary sulphur, but some principle derived from it, which constituted the philosopher’s stone or elixir—white for silver and yellow or red for gold. This is briefly the doctrine that the metals are composed of mercury and sulphur, which persisted in one form or another down to the 17th century. Of course there were numerous variations and refinements. Thus in the *Speculum Naturale* of Vincent of Beauvais (c. 1250) it is said that there are four spirits—mercury, sulphur, arsenic and sal ammoniac—and six bodies—gold, silver, copper, tin, lead and iron. Of these bodies

¹These conclusions, which are due mainly to Berthelot, have been criticized by E. J. Holmyard and by J. R. Partington (*Nature*, 1923, vol. iii., pp. 191, 219). The former believes Geber to have been Jābir ibn Haiyān (8th century), and the latter believes the Latin works are correctly ascribed to Geber.

the first two are pure, the last four impure. Pure white mercury, fixed by the virtue of white non-corrosive sulphur, engenders in mines a matter which fusion changes into silver and united to pure clear red sulphur it forms gold, while with various kinds of impure mercury and sulphur the other bodies are produced. Vincent attributes to Rhazes the statement that copper is potentially silver, and any one who can eliminate the red colour will bring it to the state of silver, for it is copper in outward appearance, but in its inmost nature silver. This statement represents a doctrine widely held in the 13th century, and also to be found in the Greek alchemists, that everything endowed with a particular apparent quality possesses a hidden opposite quality, which can be rendered apparent by fire. Later, as in the works attributed to Basil Valentine, sulphur, mercury and salt are held to be the constituents of the metals.

It must be noted that the processes described by the alchemists of the 13th century are not put forward as being miraculous or supernatural; they rather represent the methods employed by nature, which it is the end of the alchemist’s art to reproduce artificially in the laboratory. But even among the late Arabian alchemists it was doubted whether the resources of the art were adequate to the task; and in the West, Vincent of Beauvais remarks that success had not been achieved in making artificial metals identical with the natural ones. Thus he says that the silver which has been changed into gold by the projection of the red elixir is not rendered resistant to the agents which affect silver but not gold, and Albertus Magnus in his *De Mineralibus*—the *De Alchemia* attributed to him is spurious—states that alchemy cannot change species but merely imitates them—for instance, colours a metal white to make it resemble silver or yellow to give it the appearance of gold. He has, he adds, tested gold made by alchemists, and found that it will not withstand six or seven exposures to fire. But scepticism of this kind was not universal. Roger Bacon—or more probably some one who usurped his name—declared that with a certain amount of the philosopher’s stone he could transmute a million times as much base metal into gold, and on Raimon Lull was fathered the boast “Mare tingerem si mercurius esset.”

Later History of Alchemy.—In the earlier part of the 16th century Paracelsus gave a new direction to alchemy by declaring that its true object was not the making of gold but the preparation of medicines, and this union of chemistry with medicine was one characteristic of the iatrochemical school of which he was the precursor. Increasing attention was paid to the investigation of the properties of substances and of their effects on the human body, and chemistry profited by the fact that it passed into the hands of men who possessed the highest scientific culture of the time. Still, belief in the possibility of transmutation long remained orthodox, even among the most distinguished men of science. Thus it was accepted, at least academically, by Andreas Libavius (d. 1616); by F. de la Boë Sylvius (1614–72), though not by his pupil Otto Tachenius, and by J. R. Glauber (1603–68); by Robert Boyle (1627–91) and, for a time at least, by Sir Isaac Newton and his rival and contemporary, G. W. Leibnitz (1646–1716); and by G. E. Stahl (1660–1734) and Hermann Boerhaave (1668–1738). Though an alchemist, Boyle, in his *Sceptical Chemist* (1661), cast doubts on the “experiments whereby vulgar Spagyrist are wont to endeavour to evince their salt, sulphur and mercury to be the true principles of things,” and advanced towards the conception of chemical elements as those constituents of matter which cannot be further decomposed. With J. J. Becher (1635–82) and G. E. Stahl, however, there was a reversion to earlier ideas. The former substituted for the salt, sulphur and mercury of Basil Valentine and Paracelsus three earths—the mercurial, the vitreous and the combustible—and he explained combustion as depending on the escape of this last combustible element; while Stahl’s conception of phlogiston—not fire itself, but the principle of fire—by virtue of which combustible bodies burned, was a near relative of the mercury of the philosophers, the soul or essence of ordinary mercury.

Perhaps J. B. van Helmont (1577–1644) was the last distinguished investigator who professed actually to have changed mer-

cury into gold, though impostors and mystics of various kinds continued to claim knowledge of the art long after his time. Since the early years of the 20th century, however, the possibility of the transmutation of elements has entered upon a new phase. (See RADIOACTIVITY; TRANSMUTATION OF ELEMENTS; MATTER.)

ALCIATI, ANDREA (1492–1550), Italian jurist, was born in Alzano, near Milan, on Jan. 12, 1492. He was one of the first to interpret the civil law by the history, languages and literature of antiquity, and to substitute original research for the servile interpretations of the glossators. His *Emblems*, a collection of moral sayings in Latin verse, was translated into French, Italian and Spanish.

ALCIBIADES (c. 450–404 B.C.), Athenian general and politician. He belonged to the family of the Alcmaeonidae, and was a near relative of Pericles. He was very handsome and possessed great wealth, which he squandered in every sort of dissipation and extravagance, including the upkeep of a fine stud of horses (Thuc. vi. 12, 16). He was an admirer of Socrates, who saved his life at Potidaea (432), a service which Alcibiades repaid at Delium; but he could not practise his master's virtues, and there is no doubt that the example of Alcibiades strengthened the charges brought against Socrates of corrupting the youth (399). In 421 he came to the fore as the political opponent of Nicias and the peace-party, and engineered an anti-Spartan alliance between Athens and the democracies of Argos, Mantinea and Elis. Sparta was thus placed in a critical position, and the policy might have been successful had Athens given it whole-hearted support. But in 418 Alcibiades was not re-elected general, and Sparta broke up the confederacy by the crushing victory of Mantinea. On the failure of Nicias in Thrace (418–417) he became the chief advocate of the Sicilian expedition, partly from policy and partly from private ambition, and was appointed commander jointly with Nicias and Lamachus. But on the day before the expedition sailed there occurred the mysterious mutilation of the Hermæ, and Alcibiades was accused not only of being the originator of the crime, but also of having profaned the Eleusinian mysteries. He demanded an immediate inquiry, but his enemies obliged him to set sail with the charge still hanging over him. When he reached Sicily he was recalled to stand his trial, but on the journey home he escaped to Sparta. Learning that he had been condemned to death in his absence, he openly joined the Spartans and persuaded them to send Gylippus to assist the Syracusans and to fortify Decelea in Attica, advice which proved the ruin of Athens. He then passed over to Asia Minor, induced many of the Ionic allies of Athens to revolt, and made an alliance with the Persian satrap Tissaphernes. But in a few months he had lost the confidence of the Spartans and made an enemy of King Agis. He therefore retired to the court of Tissaphernes (412), and hoping to secure his recall to Athens, advised the satrap to withdraw his active support from Sparta. At the same time he conspired with the oligarchic party at Athens, who brought about a revolution in 411 but did not recall Alcibiades. He therefore attached himself to the fleet at Samos, which remained loyal to the democracy, and was recalled by Thrasybulus, but he did not at once return to Athens. Being appointed commander in the neighbourhood of the Hellespont, he defeated the Spartan fleet at Abydos (411) and Cyzicus (410), and recovered Chalcedon and Byzantium. These successes encouraged him to return to Athens, where he was welcomed with enthusiasm (407); proceedings against him were cancelled, and he was appointed general with full powers. But the Athenians did not fully trust him, and

the defeat at Notium (407) led them to dismiss him from his command. He thereupon retired to the Thracian Chersonesus. After the final defeat of Athens he took refuge in Phrygia with Pharnabazus, who was induced by the Spartans to have him murdered (404).

Alcibiades possessed great charm and brilliant abilities but was absolutely unprincipled. His advice, whether to Athens or Sparta, oligarchs or democrats, was dictated by selfish motives, and the Athenians could never trust him sufficiently to take advantage of his talents. "They feared," says Thucydides, "the extremes to which he carried his lawless self-indulgence, and . . . thought he was aiming at a tyranny . . . therefore, though his talents as a military commander were unrivalled, they entrusted the administration of the war to others; and so they speedily shipwrecked the state" (Jowett's trans.).

Grote, *History of Greece*; E. F. Benson, *The Life of Alcibiades* (1929); Ed Meyer, and works quoted under GREECE: *Ancient History*; also PELOPONNESIAN WAR.

ALCIDAMAS, of Elaea, in Aeolis, Greek sophist and rhetorician, flourished in the 4th century B.C. He was the pupil and successor of Gorgias and taught at Athens at the same time as Isocrates. We possess two declamations under his name: *Περὶ Σοφιστῶν*, directed against his rival Isocrates and setting forth the superiority of extempore over written speeches (a recently discovered fragment of another speech against Isocrates is probably of later date); *Ὀδυσσεύς*, in which Odysseus accuses Palamedes of treachery during the siege of Troy (this is generally considered spurious). Of other works only fragments and the titles have survived: *Μεσσηνιακός*, advocating the freedom of the Messenians and containing the sentiment that "all are by nature free"; a *Eulogy of Death*, in consideration of the wide extent of human sufferings; a *Τέχνη* or instruction-book in the art of rhetoric; and a *Φυσικός λόγος*. Lastly, his *Μουσείον* (a word of doubtful meaning) contained the narrative of the contest between Homer and Hesiod, two fragments of which are found in the *Ἀγών Ὀμήρου καὶ Ἡσιόδου*, the work of a grammarian in the time of Hadrian. A 3rd-century papyrus (Flinders Petrie, *Papyri*, ed. Mahaffy, 1891, pl. xxv.) probably contains the actual remains of a description by Alcidamas.

See fragments in Müller, *Oratores Attici*, ii. (1858); Vahlen, *Der Rhetor Alkidamas* (1864); Blass, *Die attische Beredsamkeit*; and the edition by Blass, 1881.

ALCINOUS (Gr. *āl-kîn-ō-ōs*), in ancient Greek legend, king of the Phaeacians, in the island of Scheria, son of Nausithous and grandson of Poseidon. His reception and entertainment of Odysseus (*q.v.*), who when cast by a storm on the shore of the island was relieved by the king's daughter, Nausicaa, is described in the *Odyssey* (vi., xiii.). Scheria was identified in very early times with Corcyra, where Alcinoüs was revered as a hero. In the Argonautic legend, his abode was the island of Drepane (Apoll. Rhodius iv., 990).

ALCINOUS, the Platonic philosopher, lived probably in the time of the Caesars. He was the author of an analysis of Plato's philosophy, and attributed to Plato ideas of other philosophers. He produced latterly a synthesis of Plato and Aristotle with an admixture of Pythagorean or Oriental mysticism, and is closely allied to the Alexandrian school of thought. He recognized a God who is unknowable, and a series of beings (*δαίμονες*) who hold intercourse with men. He recognized also ideas and matter, and borrowed largely from Aristotle and the Stoics.

The *Ἐπιτομή* has been translated by Pierre Balbi (Rome, 1469) and by Marsilio Ficino; into French by J. I. Combes-Dounous (1800); and into English by Thomas Stanley in his *History of Philosophy*. Editions: Heinsius (Leyden, 1630); Fischer (Leipzig, 1783); in Aldine Edition of Apuleius (Venice, 1521, 1532); Fell (1667). See Ritter, *Geschichte der Philosophie*, iv. 249.

ALCIPHON, Greek rhetorician, was probably a contemporary of Lucian (2nd century A.D.). He was the author of a collection of fictitious letters, of which 124 (118 complete and six fragments) have been published; they are written in the purest Attic dialect and are considered models of style. The scene is throughout at Athens; the imaginary writers are country people,

fishermen, parasites and courtesans, who express their sentiments and opinions on familiar subjects in elegant language. The "courtesan" letters are especially valuable, the information contained in them being chiefly derived from the writers of the New Comedy, especially Menander.

ALCIRA, eastern Spain, province of Valencia; on the left bank of the river Júcar. Pop. (1920) 20,839. Alcira is a walled town, surrounded by palm, orange and mulberry groves, and by low-lying and unhealthy rice-swamps. Silk, fruit, rice and cabinet woods are its chief products. It has a Roman bridge and has been thought to be the Roman Saetabula or Suero; it was later a Moorish trading station.

ALCMAEON, son of Amphiarus (*q.v.*). After the destruction of Thebes by the Epigonoï, Alcmaeon carried out his father's injunctions by killing his mother, as a punishment for which he was pursued by the Erinyes from place to place. On his arrival at Psophis in Arcadia, he was purified by its king Phegeus, whose daughter Arsinoe (or Alpheisiboea) he married, making her a present of the fatal necklace and the robe of Harmonia. But the land was cursed with barrenness, and the oracle declared that Alcmaeon would never find rest until he reached a spot on which the sun had never shone at the time he slew his mother. Such a spot he found at the mouth of the river Achelous, where an island had recently been formed by the alluvial deposit; here he settled and, forgetting his wife Arsinoe, married Callirhoe (*q.v.*), the daughter of the river-god. His new wife longed for the necklace and robe, and Alcmaeon, returning to Psophis, obtained possession of them, on the pretence that he desired to dedicate them at Delphi. When the truth became known he was pursued and slain by Phegeus and his sons. After his death Alcmaeon was worshipped at Thebes; his tomb was at Psophis in a grove of cypresses.

See Apollodorus iii. 7; Thucydides ii. 68. 102; Pausanias viii. 24. x. 10; Ovid, *Metam.* ix. 400 *et seq.*

ALCMAEONIDAE, a powerful Athenian family, which played a leading part in the politics of the 6th and 5th centuries, B.C. The murder of the Cylonian conspirators (*c.* 632) brought the pollution of blood-guilt on them (*cf.* esp. Hdt. v. 70–71 and Thuc. i. 126–127) and they were banished until the time of Solon. Alcmaeon seems to have made his fortune through the favour of the kings of Lydia. Megacles, who made a great marriage with the daughter of the ruler of Sicyon, led the merchant party in opposition to the tyrant Peisistratus, and was exiled (Hdt. i. 59); his son Cleisthenes drove out the tyrants (510), defeated the Spartan attempt to set up an oligarchy, and by his reforms secured the Athenian democracy. The Alcmaeonids were suspected, however, of treacherously helping the Persians by giving the famous shield signal at Marathon. To the same family belonged Pericles and Alcibiades.

See Herodotus vi. 121–131, and articles on **CLEISTHENES**, **PERICLES**, **ALCIBIADES**, **GRAECO-PERSIAN WARS** and *Camb. Anc. Hist.* vol. iv. ch. vi., § 6 and ch. viii.

ALCMAN or **ALCMAEON** (*fl.* in the 7th cent. B.C.), the founder of Doric lyric poetry, to whom was assigned the first place among the nine lyric poets of Greece in the Alexandrian canon. He was a Lydian of Sardis, who came as a slave to Sparta, where he was emancipated and given the citizenship. Alcman composed various kinds of poems in various metres; Parthenia (maidens' songs), hymns, paeans, prosodia (processionals), and love-songs, of which he was considered the inventor. The fragments are scanty, the most considerable being part of a *Parthenion* found in 1855 on an Egyptian papyrus; some hexameters discovered in 1898 are attributed to Alcman or Erinna (*Oxyrhynchus papyri*, i. 1898).

For general authorities see **ALCAEUS**.

ALCMENE (älk-mā-nā), in Greek mythology the daughter of Electryon, king of Mycenae, and wife of Amphitryon. She was the mother of Heracles by Zeus, who assumed the likeness of her husband during his absence.

See Plautus, *Amphitruo*.

ALCOBAÇA, a town of Portugal, in the district of Leiria. Pop. (1920) 2,661. Alcobaça is chiefly interesting for its Cistercian convent, now partly converted into schools and barracks. The monastic buildings, a square, 725ft. across, were founded in 1148 and completed in 1222. During the middle ages it rivalled the greatest European abbeys in size and wealth. It was supplied with water by an affluent of the Alcoa, which still flows through the kitchen. The convent was partly burned by the French in 1810, secularized in 1834, and afterwards gradually restored. Portions of the library are now preserved in the public libraries of Lisbon and Braga. The monastic church (1222) is a good example of early Gothic, somewhat defaced by Moorish and other additions.

ALCOCK, JOHN (*c.* 1430–1500), English divine, was born at Beverley in Yorkshire and educated at Cambridge. He was bishop successively of Rochester, Worcester and Ely, and twice held the office of lord chancellor. He died at Wisbech Castle Oct. 1, 1500. Alcock was one of the most eminent pre-Reformation divines; he was a man of deep learning and also of great proficiency as an architect. Besides founding a charity at Beverley and a grammar school at Kingston-upon-Hull, he restored many churches and colleges; but his greatest enterprise was the erection of Jesus College, Cambridge, which he established on the site of the former convent of St. Radigund.

Alcock's published writings, most of which are extremely rare, are: *Mons Perfectionis, or the Hill of Perfection* (London, 1497); *Gallcontus Johannis Alcock episcopi Eliensis ad fratres suos curatos in sinodo apud Barnwell* (1498), a good specimen of early English printing and quaint illustrations; *The Castle of Labour*, translated from the French (1536); and various other tracts and homilies.

See J. Bass Mullinger's *Hist. of the University of Cambridge*, vol. i.

ALCOCK, SIR JOHN WILLIAM (1892–1919), English airman, was born in Manchester on Nov. 6, 1892, the son of a horse dealer. Before the World War he had been in possession of the aviation certificate for two years, when he joined the Royal Naval Air Force as an instructor in 1914. In 1916 he was posted at No. 2 wing at Mudros. Here he performed many famous exploits, including the bombing of Constantinople on Sept. 30, 1917. He was forced to alight at sea near Suvla bay on his return from this expedition, and he and his companions swam ashore, and were taken prisoners by the Turks. After leaving the Air Force in March 1919, he made a flying record with Lieut. Arthur Whitten Brown by flying from St. John's, Newfoundland, to Clifden, Ireland, in 16hrs. 12mins. He was then created K.B.E. A week later Alcock was flying to Paris in an amphibian aeroplane when he sustained fatal injuries at Côte d'Evvard, Normandy, on Dec. 18, 1919. See **AVIATION**; **TRANS-OCEANIC AND TRANS-CONTINENTAL FLIGHTS**.

ALCOCK, SIR RUTHERFORD (1809–1897), British consul and diplomatist, practised medicine until 1837. In 1844 he became consul at Fuchow in China, opened to trade by the treaty of 1842, and Mr. Alcock, as he then was, had to maintain an entirely new position with the Chinese authorities. He went in 1846 to Shanghai and there superintended the establishment and laying out of the British settlement. In 1858 he was appointed consul-general in the newly opened empire of Japan, and in the following year was promoted to be minister plenipotentiary. In 1860 Mr. Alcock's native interpreter was murdered at the gate of the legation, and in the following year the legation was stormed by a body of Ronins, whose attack was repulsed by Mr. Alcock and his staff. After a brief period at home he returned to Japan in 1864 and he was transferred to Peking in 1865, where he represented the British Government until 1871. Alcock was one of the first to awaken in England an interest in Japanese art; his best-known book *The Capital of the Tycoon*, appeared in 1863. He died in London on Nov. 2, 1897.

See A. Michie, *The Englishman in China during the Victorian Era, as illustrated in the career of Sir Rutherford Alcock* (Edinburgh, 1910).

ALCOFORADO, MARIANNA (1640–1723), writer of the *Letters of a Portuguese Nun*, was the daughter of a landed proprietor in Alemtejo. She made her profession as a Franciscan nun at 16 or earlier, without any real vocation, and lived a routine life in the convent of the Concepcion at Béja until her 25th year.

when she met Noel Bouton, afterwards marquis de Chamilly, and marshal of France. During the years 1665-67 Chamilly spent much of his time in and about Béja, and probably became acquainted with the Alcoforado family through Marianna's brother, who was a soldier. Custom then permitted those in religious orders to receive and entertain visitors, and Chamilly began an intrigue with Marianna which caused a scandal. To avoid the consequences Chamilly deserted Marianna, and withdrew clandestinely to France. The letters to her lover were written between Dec. 1667 and June 1668, and describe the successive stages of faith, doubt and despair through which she passed. These five short letters written by Marianna to "expostulate her desertion" have become a classic. There are signs in the fifth letter that Marianna had begun to conquer her passion, and after a life of rigid penance, accompanied by much suffering, she died at the age of 83. The letters came into the possession of the comte de Guilleragues, director of the *Gazette de France*, who turned them into French, and they were published anonymously in Paris in Jan. 1669. In 1810 Boissonade discovered Marianna's name written in a copy of the first edition by a contemporary hand, and the veracity of this ascription has been placed beyond doubt by the investigations of Luciano Cordeiro, who found a tradition in Béja connecting the French captain and the Portuguese nun.

The foreign bibliography of the *Letters*, containing almost 100 numbers, will be found in Cordeiro's admirable study, *Soror Marianna, A Frieria Portuguesa*, 2nd ed. (Lisbon, 1891). Besides the French editions, versions exist in Dutch, Danish, Italian and German; and the English bibliography is given by Edgar Prestage in his translation *The Letters of a Portuguese Nun (Marianna Alcoforado)*, 3rd ed. (1903). The French text of the *editio princeps* was printed in the 1st ed. (1893) of this book. Edmund Gosse in the *Fortnightly Review*, vol. xlix. (old series) p. 506, shows the considerable influence exercised by the *Letters* on the sentimental literature of France and England.

ALCOHOL, the name applied to any member of a class of organic compounds (see *ALCOHOLS*). The word is of Arabic origin, being derived from the particle *al* and the word *kohl*, an impalpable powder used in the East for painting the eyebrows. For many centuries the word was used to designate any fine powder; its present day application is of comparatively recent date. Thus Paracelsus and Libavius both used the term to denote a fine powder, the latter speaking of an *alcohol* derived from antimony. Paracelsus also used the term to denote a volatile liquid; *alcohol* and *alcohol vini* occur often in his writings, and once he adds *id est vino ardente*.

The word is commonly applied to one particular member of the class (ethyl alcohol or ethanol) having the formula C_2H_5O . Alcohol, as an article of widespread consumption and use, has various other names, e.g., "Spirits of Wine," "Eau de Vie," "Aqua Vitae."

Ethyl alcohol does not occur in appreciable quantities in nature except under abnormal conditions, the most common instances being the urine of persons suffering from diabetes or those addicted to excessive consumption of alcoholic beverages. In the vegetable kingdom it occurs, mixed with ethyl butyrate, in the unripe seeds of *Heracleum giganteum* and *H. sphondylium*. In consequence, however, of its ready formation by the fermentation of saccharine juices of vegetable origin, it has been known, in its impure state, from ancient times. It was not until 1808 that its constitution was determined by de Saussure, although Lavoisier had previously established its qualitative composition. Sir Edward Frankland, by demonstrating its relation to the hydrocarbon ethane ($CH_3 \cdot CH_3$), proved it to be $CH_3 \cdot CH_2OH$, one hydrogen atom of the ethane molecule being replaced by the hydroxyl group. Ethyl alcohol may be synthetically prepared by any of the general methods described in the article *ALCOHOLS*. The mechanism of alcoholic fermentation is discussed in the article *FERMENTATION*, and the manufacture of alcohol from fermented liquors in the article *SPIRITS*.

Properties.—Pure ethyl alcohol is a mobile colourless liquid having an agreeable ethereal odour. It boils at $78.3^\circ C$ at a pressure of 760mm. of mercury; at $-90^\circ C$ it is a thick liquid, whilst at $-130^\circ C$ it solidifies to a white mass. Its specific gravity at various temperatures is as follows, the gravities being compared with water at $4^\circ C$:

Temp., $^\circ C$.	Sp. Grav.	Temp., $^\circ C$.	Sp. Grav.
10°	0.79784	30°	0.78075
15°	0.79360	35°	0.77641
20°	0.78934	40°	0.77203
25°	0.78506		

Its high coefficient of thermal expansion, coupled with its low freezing point, renders it a valuable thermometric fluid, especially when the temperatures to be measured are below $-39^\circ C$ when the mercury thermometer cannot be used. It burns readily in air with a blue smokeless flame, producing water and carbon dioxide. Since its combustion is attended with the evolution of great heat, alcohol is used extensively as a fuel.

Ethyl alcohol is miscible with water in all proportions, the mixing being accompanied by a contraction in volume and a rise in temperature. The maximum contraction corresponds approximately to a mixture of three molecules of alcohol and one of water. Owing to the energy with which it absorbs moisture from the air, it is difficult to obtain or preserve ethyl alcohol in a completely anhydrous state. Commercial alcohol, which usually contains about 95% of the pure alcohol and 5% of water, can be obtained by fractional distillation of spirituous liquors. This method of purification fails to remove the last traces of water, which can only be effected by distilling the commercial product after it has stood in contact with a dehydrating agent such as quick-lime, baryta, or anhydrous copper sulphate, or by taking advantage of its peculiar behaviour when mixed with benzene. Calcium chloride must not be used, as it forms a crystalline compound with alcohol, the latter playing the rôle of water of crystallization. The presence of water in alcohol may be detected in several ways. Aqueous alcohol, when mixed with benzene, carbon disulphide, or paraffin oil, becomes turbid. A more delicate method is the addition of a small quantity of anthraquinone and sodium amalgam, when absolute alcohol gives a green coloration, but in the presence of minute traces of water a red coloration is obtained.

Traces of ethyl alcohol can be detected by converting it into ethyl benzoate on shaking with benzoyl chloride and caustic soda; by warming it with iodine and potassium hydroxide and thus producing iodoform, which is recognized by its characteristic odour; or by oxidation to acetaldehyde. The latter test is elaborated by distillation into a strong solution of sodium hydroxide, when an "aldehyde resin" easily recognized by appearance and smell is formed.

Determination.—The quantity of alcohol present in a mixture of alcohol and water can readily be determined. If other substances are present, it is usually necessary to separate them by distillation and sometimes by preliminary chemical treatment. The determination may be made by ascertaining the vapour tension or by finding the boiling point. The most common and convenient method, however, is the determination of the specific gravity of the aqueous mixture. This can be ascertained by means of some form of pyknometer or hydrometer, standard tables being available which correlate gravities with proportion of alcohol. The latter may be expressed in various forms, depending upon the requirements of the Government or other authority by whom the tables have been prepared. The usual form is percentage of absolute alcohol by weight or by volume. The former has certain advantages as it is independent of temperature, whilst the latter, owing to the difference in the coefficients of expansion of the two ingredients, is subject to thermal variation. In the United Kingdom and in America arbitrary standards called "Proof Spirit" are used. British "Proof Spirit" is that mixture of alcohol and water which at the temperature of $51^\circ F$ weighs exactly $\frac{1}{2}$ of an equal measure of distilled water also at $51^\circ F$. It contains 49.28% of alcohol by weight, and at $60^\circ F$ it contains 57.10% of alcohol by volume and has a specific gravity of 0.91976. The "quantity at proof" is given by the formula; (quantity of sample)

$$\times \frac{(\text{percentage of proof spirit})}{100} \quad \text{United States "Proof Spirit" is}$$

that which at $15.6^\circ C$ contains exactly one-half its volume of alcohol.

The hydrometer used varies considerably and may indicate directly specific gravity, proportion of alcohol, or have an arbitrary scale, the readings of which have to be referred to tables. Sikes's hydrometer, the British legal instrument, is of the last-mentioned type. It was devised by Bartholomew Sikes, an English excise officer, at the end of the 18th century. The tables now used with it, however, are of modern compilation, and were legalized in 1915. Sikes's system has been extended by the addition of two hydrometers "A" and "B" to cover all strengths up to absolute alcohol at 84° F.

Yet another physical property which is frequently used for detecting and estimating ethyl alcohol is the refractive index. Holmes (see *Trans. Chem. Soc.*, 1913, 103, p. 2,165) gives the following indices of refraction (n_D) at 15.5° C for molecular mixtures of alcohol with water, that of pure alcohol being 1.36316:

Alcohol (mols.).	Water (mols.).	n_D	Alcohol (mols.).	Water (mols.).	n_D
4	1	1.36574	1	2	1.36408
2	1	1.36651	1	3	1.36152
1	1	1.36630	1	4	1.35883

Holmes found the maximum value 1.36661 to correspond to a mixture containing 79.2% of alcohol by weight.

Uses.—The most important industrial application of ethyl alcohol is as a solvent. It dissolves a large number of solid and liquid organic compounds, resins, hydrocarbons, fatty acids, and many mineral salts. Potassium and sodium readily dissolve in it, yielding alcoholates (ethoxides) in the form of voluminous white powders. With sulphuric acid it yields ethyl sulphuric acid and with sulphuric anhydride diethyl sulphate. The phosphorus haloids give the corresponding ethyl haloids. It is readily oxidized into acetaldehyde and acetic acid by such agents as manganese peroxide and sulphuric acid. With bleaching powder it yields chloroform, whilst with iodine and potassium hydroxide it reacts to give iodoform. Most gases dissolve in it more readily than in water; for instance 100 volumes will dissolve seven volumes of hydrogen, 25 volumes of oxygen or 16 volumes of nitrogen. (For industrial uses, see ALCOHOL IN INDUSTRY.)

Pharmacology, Toxicology and Therapeutics of Alcohol.

—The great solvent power of alcohol is of high medicinal value in the preparation of solutions of alkaloids, resins, volatile oils, iodoform, etc. The effect of alcohol when applied externally to the human body depends upon the strength of the solution and the conditions of application. When of a strength above 10% it is antiseptic. If applied in such a manner that evaporation can take place readily, it has a cooling effect of which advantage is often taken by bathing the forehead with perfume to soothe headache. If on the other hand evaporation is retarded, the affinity of alcohol for water causes its extraction from the tissues, which become hardened. Thoroughly rubbed into the skin, alcohol dilates the blood vessels and produces a mild counter-irritant effect. Many alcoholic liniments are therefore employed for the relief of pain, especially lumbago and other forms of so-called "muscular rheumatism." When taken internally alcohol is completely and rapidly absorbed from the stomach and intestines and distributed by the blood to different organs of the body. The rate of absorption is checked if the alcohol is diluted either with water or with food taken immediately before drinking. A variable but small proportion of alcohol escapes unchanged in the breath and urine. The remainder is slowly oxidized in the body, disappearing at a uniform rate of about 0.185 cu.cm. per kg. of body per hour. None is known to be converted into substances which the body can retain.

The effects of consumption of alcohol are almost all due (directly or indirectly) to its action upon the nervous system. Thus the immediate sensation of well-being is due to the flushing of the skin, suppressing temporarily the sense of chill and to the fact that the sensibility to minor pains and inconveniences becomes blunted; whilst with larger doses the diminution of the power of self-control and sense of personal responsibility gives rise to excitability. In the secondary stage the fineness of the senses (hearing, touch, taste and vision) is affected, and this gives rise to an inability to control bodily movements such as facial expression.

In the advanced stage of drunkenness, the intellectual processes of judgment and control are suspended, and in the absence of a strong appeal to emotional tendencies the drinker sinks inert and nerveless into a heavy sleep or condition of torpor, which lasts until the alcohol absorbed has all been oxidized. (See DRUNKENNESS; DELIRIUM.)

A dose of alcohol (such as would be present in 2½ oz. of whisky or 1½ pints of beer) exerts no influence on the performance of simple muscular acts not demanding precision. For acts requiring skill or accuracy efficiency is temporarily impaired by such a dose. The digestion is not affected by a moderate amount of alcohol, the deleterious results of consuming alcoholic beverages being probably due to other substances; e.g., non-volatile bodies in wine, and higher alcohols and esters in distilled drinks such as brandy or whisky. Contrary to the common belief, alcohol does not act as a direct stimulant to the heart in cases of threatened failure. Recovery from fainting is probably due to the irritant action on the mucous membrane of the nose and throat comparable to that of smelling salts or burnt feathers. In protracted weakness the beneficial effect of alcohol appears to be due to its mildly narcotic and sedative action relieving the centres which in conditions of anxiety or pain affect the action of the heart. For the purpose of "keeping out the cold" alcohol is probably not harmful in a small dose, as it promotes activity, but as a preliminary to long exposure it is dangerous. It renders the drinker subject to an illusion of warmth and indifferent to the peril of extreme cold which may result fatally. At the end of long exposure, however, after the patient has been placed in hot blankets a moderate dose of alcohol is beneficial, promoting the return of the blood to the superficial tissues to which the extreme heat is applied.

Excessive consumption of alcohol tends to shorten life, but it is uncertain if moderate drinking has any effect on longevity. The following extract from the British official returns is of interest in this connection, the year 1900 being inserted as the "peak" year under both headings.

	Consumption per head of the population			Death rate per million of the population	
	Beer, gals.	Spirits, Pf. gals.	Wine, gals.	From alcoholism	From cirrhosis of the liver
1897	30.23	1.20	0.40	77	133
1900	32.04	1.22	0.42	113	144
1922	17.67	0.37	0.24	14	46

After death the presence of alcohol can be detected in all the body fluids. Its especial affinity for the nervous system is indicated by the fact that, when all traces of it have disappeared elsewhere, it can still be detected with ease in the cerebro-spinal fluid. (See PHARMACOLOGY, and *Alcohol: Its Action on the Human Organism*, Medical Research Council, 1924.)

Fiscal.—Ethyl alcohol is a fruitful source of revenue to most of the Governments of the world. In Great Britain the excise duty on spirits varies from £3 12s. 6d. to £3 14s. per proof gallon, and the customs duty is in some instances as high as £6 3s. 5d. per liquid gallon. Both duties, however, are liable to considerable modification in certain circumstances. The revenue derived from the spirit duties has recently shown steady decline:—

Financial Year	Net Receipts from Customs and Excise.
1923-24	£54,036,746
1924-25	£51,053,606
1925-26	£49,927,045
1926-27	£43,552,785

In the U.S.A. the adoption of prohibition has greatly diminished the revenue importance of alcohol. Thus whilst in the fiscal year 1919 the yield of internal revenue tax on distilled spirits (including wines, etc.) and fermented liquors was \$483,050,854 40, in 1926 it was only \$26,452,028.63. The import duty on non-beverage alcohol is 15 cents per gallon, and on brandy and similar articles—imported for special purposes only—\$5.00 per proof gallon. The quantities of distilled liquors in proof gallons imported in recent years have been as follows:—

1924	52,676	1926	71,622
1925	57,679	1927 (1st 9 months only)	50,971

The great industrial importance of alcohol has necessitated the introduction of a duty-free product retaining its suitability for the many purposes for which it may be used in the arts and manufactures. (For details of "denatured alcohol" see ALCOHOL IN INDUSTRY.) (J. J. F.; F. G. H. T.)

ALCOHOL, PATHOLOGICAL EFFECTS OF. The pathological effects of alcohol are due to a chronic poisoning rather than an acute. Large doses may, however, cause death almost instantaneously by a reflex action on the heart or by cardiac and respiratory depression after the drug has been absorbed. If the alcohol be taken in the form of spirits, the subject usually becomes thin, probably owing to the spirits so affecting the gastro-intestinal tract that little or no nourishment is absorbed; if beer be the form of drink the subject is liable to become fat. Prolonged drinking of any form of alcohol makes persons less able to withstand operations and diseases, such as phthisis and pneumonia, and is the direct cause of certain diseases of which the chief are the following:

Chronic Gastritis.—This is most likely to occur in those who drink spirits. The action of the strong alcohol on the stomach sets up an inflammatory condition which, owing to the continued action of the irritant, never subsides, with the result that permanent damage results and the proper digestion of food cannot take place and the patient becomes thinner and thinner.

Cirrhosis of the Liver (gin-drinker's liver).—The quantity of alcohol associated with this condition differs with different persons; in some cases a few months' indulgence may suffice, in others it may be a matter of years. Whether the alcohol itself or some toxin due to gastro-intestinal disturbance acts on the liver is not certain, but the result is a chronic inflammation which passes on to an extensive growth of fibrous tissue. This by its contraction compresses and destroys the liver cells and seriously impedes the flow of blood through the veins of the organ. The size of the liver varies within wide limits, but is usually small owing to the contraction of the fibrous tissue. The most important and constant result of this contraction is the effusion of fluid from the compressed and distended veins into the peritoneal cavity, constituting one of the types of dropsy called ascites. The patient gradually becomes more and more ill and death often ensues within a few months of the appearance of ascites. (See LIVER, DISEASES OF.)

Multiple or Peripheral Neuritis (see NEURITIS).

Gout (*g.v.*).—The habitual drinking of heavy or sweet wines is one of the causes of this disease, as is excessive beer drinking when combined with poor or insufficient food.

Mania may at times be due to chronic alcoholic poisoning and possibly chronic Bright's disease. Certainly the kidneys will be affected more or less adversely by the toxins due to the gastro-intestinal disturbance.

Delirium tremens (see DELIRIUM) occurs in habitual drinkers.

ALCOHOL IN INDUSTRY. Owing to its very high price, duty-paid alcohol cannot be used for most industrial purposes (even in "wet" countries); exhaustive experiments were therefore carried out in England about the year 1853 to ascertain whether it would be possible so to treat alcohol as to enable it to be used industrially without any risk of the revenue being defrauded.

Industrial Methylated Spirits.—The experiments of 1853 resulted in the legislation of 1855 which authorized the use, for purely manufacturing purposes, of duty-free spirits mixed with 10% by volume of wood naphtha (an impure methyl alcohol), the product being unfit for beverage purposes and known as "methylated spirits." By the Revenue Act of 1906 "methylated spirits" became "industrial methylated spirits" and the volume of wood naphtha was reduced to 5%. Methyl alcohol (*g.v.*) was selected because it is very difficult to remove even by distillation, and because its presence can readily be detected. Industrial methylated spirits are for use in industrial and other operations for which mineralized methylated spirits are unsuitable. By the regulations dated Dec. 7, 1925, a pharmaceutical chemist may be authorized to obtain industrial methylated spirits for sale as such or for other specified purposes under defined conditions.

Industrial Methylated Spirits (Pyridinized).—Regulations dated Dec. 7, 1925, authorized industrial methylated spirits, having the same composition as industrial methylated spirits, with an added $\frac{1}{2}$ of 1 part of crude pyridine, to be used in the manufacture of "finish" for sale.

Mineralized Methylated Spirits.—From 1861 to 1891 methylated spirits were allowed to be sold by retail in Great Britain in small quantities for domestic purposes, but use in large quantities or in manufacture was only possible under excise supervision. In 1890, a new form known as "mineralized methylated spirits" was introduced, free from revenue supervision, for general use, the difference consisting in the further addition of $\frac{3}{8}$ of 1% of mineral naphtha. Mineralized methylated spirits in 1928 are a mixture of 90 parts by volume of alcohol, $9\frac{1}{2}$ parts of wood naphtha, and $\frac{1}{2}$ part of crude pyridine, adding to every 100 gallons of the mixture $\frac{3}{8}$ gallon of mineral naphtha and not less than $\frac{1}{16}$ oz. of powdered aniline dye (methyl violet).

Power Methylated Spirits.—Following on a report by a departmental committee in 1918, clauses were inserted in the Finance Act of 1920 legalizing the use of alcohol for power purposes under the name of "power methylated spirits." The regulations were issued in 1921, and such spirits are prepared according to the following formula:—92 parts of alcohol, 5 parts of benzol, $\frac{1}{2}$ part of crude pyridine and $2\frac{1}{2}$ parts of wood naphtha, together with $\frac{1}{16}$ oz. of Spirit Red III. dye in each 100 gallons of the mixture. Spirits so prepared are sold free of duty and restriction when mixed with 25% of petrol, benzol, denatured ether or some other approved substance.

Non-dutiable (Specially Denatured) Spirits.—The Finance Act of 1902 made it possible to use duty-free spirits in any art or manufacture when it is proved that the use of methylated spirits is unsuitable or detrimental. The spirits must be rendered unfit for use as a beverage before and during use. Frequently a suitable denaturant is found in some acid used or produced during the manufacturing operations, or the alcohol is a constituent of some mixed solvent. Thus the employment of pure alcohol denatured with 2% of pure methyl alcohol is allowed in the production of insulin without onerous excise restrictions. The use of pure duty-free spirits by "universities, colleges and other public institutions for research and teaching" are laid down in regulations issued in May 1911.

Customs and Excise.—Under the Finance Act of 1921 an allowance of 5d. per proof gallon, equivalent to about 8d. per bulk gallon, is made on spirits used for preparing industrial methylated spirits and power methylated spirits; or on spirits received for use in the arts and manufacture. Imported spirits used for the manufacture of mineralized methylated spirits are charged a differential duty of 2s. 10d. or 2s. 11d. per proof gallon if foreign, and 4d. or 5d. per gallon if empire. When used for other purposes, empire spirits are free of duty, while foreign spirits are charged 2s. 6d. per proof gallon. A rebate under the Finance Act of 1921 amounting to 80% of the present duty is made in the case of duty-paid spirits used for medicinal and for scientific purposes.

Industrial Uses of Alcohol.—Apart from its use as a beverage, alcohol is the raw material for the manufacture of vinegar, ether and chloroform, and enters into the composition of many dye stuffs. It is largely used as a solvent for the preparation of pure chemicals as well as for cleaning purposes. Various scientific operations require its use, as does also the preservation of museum and hospital specimens.

Out of a total of rather over 4 million bulk gallons of industrial methylated spirits used during the year 1926–27, $2\frac{1}{2}$ million gallons were employed for varnishes, "finishes," stains and paints. Of this quantity "finish" accounted for nearly 300,000 gallons of *pyridinized spirits*. The balance was distributed under 60 headings. The other chief uses were ether, 271,400 gallons; oil-cloths, leather-cloths and similar substances, 241,212 gallons; soap, 172,661 gallons; and hospitals, asylums and infirmaries, 104,387 gallons. *Mineralized methylated spirits* are largely used for burning in lamps and for cleaning purposes. The quantity used in a year is about $1\frac{1}{2}$ million bulk gallons. *Power methylated spirits* must be mixed with petrol or benzol, or denatured ether, and when so

mixed may be distributed and used without restrictions for power purposes.

The following table gives the quantity in bulk gallons of the various descriptions of methylated spirits issued in the United Kingdom during the years specified:—

	1913-14.	1925-26.	1926-27.
Industrial methylated spirits	3,253,061	4,247,347	4,039,809*
Mineralized methylated spirits	1,754,514	1,446,358	1,593,022
Power methylated spirits	91,282	46,447
Non-dutiable spirits	438,583	439,338	355,405
Totals	5,446,158	6,224,325	6,034,683

*Includes 304,778 gallons industrial methylated spirits (pyridinized).

A great extension has occurred in the use of methyl alcohol for industrial purposes, apart from its use for denaturing, namely, from 38,000 gallons in 1913-14, to 300,000 gallons in 1926-27.

Industrial Alcohol in the British Dominions, etc.—The regulations governing the use of industrial alcohols in the British dominions, colonies and protectorates are generally similar to those of the Imperial Government. In *Australia* there are four classes, and the principal substances used as denaturants are wood naphtha, pyridine, benzene, benzine (petroleum) and crystal violet. In *Canada* there are three grades of "denatured alcohol" and seven grades of "specially denatured alcohol"; wood alcohol is the main denaturant, but benzine, iodine, benzol, nitrobenzol and other substances are used. There are four kinds of "methylated spirits" used in *New Zealand*, the denaturants being wood naphtha and also pyridine, mineral naphtha, turpentine and shellac, according to the intended use. "Methylated spirits" in the *Union of South Africa* are denatured with crude methyl alcohol and pyridine bases, or with Simonson oil and pyridine bases. For denaturing motor fuel the same denaturants are employed. In *Kenya Colony* "industrial alcohol" is denatured with crude methyl alcohol with or without pyridine bases, or, when used as a fuel for internal combustion engines, with sulphuric ether and pyridine bases. "Denatured spirits" in *Mauritius*, including spirits used as motor fuel, are denatured with wood naphtha and pyridine, or kerosene and pyridine. In *India* the generally accepted official formula prescribes the addition of 0.5% light caoutchoucine and 0.5% pyridine bases of mineral origin. In the *West Indies* methylated spirits are always denatured with wood naphtha or methyl alcohol with, in some cases, the addition of mineral naphtha.

Industrial Alcohol in Other Countries.—The Netherlands legalized the use of denatured alcohol in 1865; in 1872 France permitted its use under a special tax, and in Germany its employment was authorized in 1879, the other European countries following—Austria in 1888, Italy in 1889, Sweden in 1890, Norway in 1891, Switzerland in 1893 and Belgium in 1896. Alcohol was used in Germany for many years before the war in increasing quantities as a source of heat, but its application for light and power started about 1887. In 1895 a distillation tax was imposed from which a refund was paid on alcohol used for other than beverage purposes.

In France a formula for general use has been approved which prescribes that to 100 litres of spirit, which must not contain more than 1% of essential oils and must indicate at least 90% alcohol at 15° C., must be added 5.5 litres of "Methylene type régie." The latter must indicate at least 90% alcohol, contain 25% acetone and at least 2.5% pyrogenous impurities produced by wood distillation. Should the use to which the alcohol is to be put justify such a course, a special formula for denaturing is allowed.

In Germany, apart from special substances added to denature alcohol for use in medicaments and foodstuffs, the materials added to alcohol destined for industrial use are as follows:—2.5 litres of wood spirit, or 1 litre of pyridine bases, or 0.025 litre of animal oils, or 1 litre of turpentine oil, or 2 litres of toluene, or 2 litres of benzine, or 0.5 kilogramme of centralite, for 100 litres of denatured spirit. For internal combustion engines 1.25 litres of a mixture of 2.5 parts wood spirit to 1 part of pyridine, 0.25 litres of methyl violet solution and from 2 to 20 litres of benzol may be added to 100 litres of spirit. For special industrial pur-

poses other mixtures are allowed, the chief denaturants being shellac, camphor, carbon tetrachloride or ether. The use of duty-free pure alcohol is allowed in public hospitals and scientific institutions, and for the manufacture of fulminates, fuzes and smokeless powders.

France denatured 12 million bulk gallons in 1922, and 19 million bulk gallons in 1925. The quantity of alcohol used for industrial and other purposes in Germany is on the increase; in 1924-25 it amounted to nearly 24½ million bulk gallons, whereas in 1925-26 it reached nearly 26½ million.

POWER ALCOHOL

Whilst alcohol can be used like petrol (gasolene) in motor engines, it cannot be used with maximum efficiency by itself in engines of modern motor vehicles because it requires a higher degree of compression than such engines are usually designed to stand, and also because, unless special arrangements are made, a motor engine will not start readily from the cold on alcohol. After mixture with benzol or petrol, or with ether in varying proportions, it can, however, be employed successfully. In the event of its production proving a commercial possibility it should, therefore, form a valuable addition to the liquid-fuel resources of the world.

In the appended table are given some comparative figures in connection with commercial petrols and alcohol, taken from a paper by H. R. Ricardo published in the *Automobile Engineer* (1921):—

Alcohol and Petrol as Fuel

	Sp. gr. at 15° C.	Latent heat at const. press. (atmospheric) B. Th. U. per lb.	Corrected "Lower" calorific value B. Th. U. per lb.*	Minimum consumption at 5:1 compn., lb. per I. H. P. hours.	Corrected thermal efficiency per cent.	Minimum consumption at highest useful compn. lb. per I. H. P. hours.
Petrols from to	0.704 0.782	132 142	18,580 19,250	0.414 0.425	31.6 31.9	0.389 0.435
Alcohol 95 vol. %	0.815	442	11,130	0.705	32.5	0.565

*The lower calorific value plus the latent heat of evaporation at constant volume.

Miscibility.—Alcohol of the strength usually employed as a liquid fuel, viz., 95% by volume, will mix with ether in all proportions, and motor fuels consisting of alcohol and ether are in use; e.g., Natalite. Alcohol will not form a stable mixture with benzol or petrol under all conditions of temperature, but increased miscibility at low temperature can be obtained by the addition of a third substance, and higher alcohols, of which butyl and amyl alcohol are the best, and many other liquids, have been patented for the purpose. If anhydrous or absolute alcohol is employed, miscibility with petrol is obtained under all practical conditions of use.

Absolute Alcohol.—The production of absolute alcohol is based on two main processes, (1) the use of solid and liquid dehydrating agents, and (2) dehydration by distillation of alcohol in the presence of liquids immiscible with water, such as benzene. The high latent heat of evaporation of alcohol explains very largely its anti-detonating effect on petrol, and this property will lead to its more general use as an anti-detonant.

Production of Power Alcohol.—Investigations started by the British Government in 1920 have shown, according to the official memorandum, that:—"The production of alcohol in any considerable quantities from vegetable materials grown in the United Kingdom is not economically possible owing to:—(1) insufficient acreage, (2) the high cost of cultivation and harvesting, (3) the high cost of manufacture, and (4) the fact that the most suitable raw materials are also important food stuffs." In a further memorandum, issued in 1925, the conclusion was reached that, of the materials considered for the purpose, viz., potatoes, mangolds and Jerusalem artichokes, the last named would seem

to be a possible source, but in an emergency only. Another official memorandum, issued in Dec. 1921, suggested that there were possibilities in some of the dominions, colonies and protectorates of making alcohol from molasses, and from suitable root and tuber crops, but not for export to this country in view of the low price of petrol.

An investigation has been made as to the possibility of employing cellulosic materials such as the grasses of Australia and Africa, and the waste vegetable products such as maize and rice straw, corn cobs, rice husks, sisal hemp waste, etc. A report made by the fuel research division of the department of scientific and industrial research, was issued in July 1927. The results of this work have established the details of a process consisting in a weak acid hydrolysis of the material, which converts the hemicellulose of the plant into simple pentose sugar, and the subsequent fermentation of the sugar, by means of a special micro-organism, into a liquid consisting of about 90% of alcohol and 10% of acetone—a more efficient fuel for internal combustion engines than alcohol alone.

Alcohol can also be produced from carbide, but this would only be possible commercially where very cheap power is available. The ethylene contained in coal and coke oven gases can be converted into alcohol, but even should it be possible to work out a cheap process, the ethylene that could be made available from these sources, would not be likely to add very much to the world's liquid fuel supplies. The progress made recently in the liquefaction of coal and in the catalytic synthesis of organic liquids from carbon monoxide and hydrogen makes it probable that the liquid fuel requirements of coal-producing countries will be met by these means in the not very distant future.

Power Alcohol in the British Empire.—Substantial efforts to manufacture and use power alcohol have been made in *British Guiana*, several sugar plantations producing it. The use of the mahua flower (*Bassia latifolia*) to produce power alcohol has been taken up by the *Hyderabad* State Government, and a factory has been erected at Kamareddi. The possibilities of making alcohol in *Malaya* from the juice of the nipa-palm have been the subject of investigation. The chances of success would appear to be promising. A large factory for the production of an alcohol-ether motor fuel has been built in *Mauritius*. In *Natal* a motor fuel composed of approximately 55 parts of alcohol and 45 parts of ether, and known as "Natalite," is manufactured from molasses and, to some extent, from maize. Motor fuel was being produced successfully in 1923 in *New Zealand* from waste potatoes, grain, fruit, molasses and various shrubs and roots. In *Queensland* a factory in the Mackay sugar district has been built with an output of about a million gallons of 95% alcohol a year. In *South Africa*, also, a good deal of attention has been devoted to the question of producing industrial and power alcohol from crops.

Power Alcohol in Other Countries.—Argentina has a "Carburante Nacional" composed of 50% of 98.4% alcohol, and 50% petrol by volume. An alcohol-ether motor fuel is produced in Cuba from molasses. Czecho-Slovakia produces a composite fuel known as "Dynamol," a mixture of approximately 3 parts of alcohol to four parts of benzol. Work is being done at Strendstruf in Denmark on the cultivation of special potatoes of high starch content. In France a law was passed in 1923 prescribing a "Carburant National." It requires all importers of petrol, benzol, benzene, toluene and coal distillation products, either alone or mixed, to purchase from the state a quantity of absolute alcohol corresponding to a minimum of 10% on the quantity of petrol, etc., imported during the preceding month. The alcohol is to be used exclusively in motor fuels consisting of not less than 95 and not more than 105 parts by volume of absolute alcohol to 100 parts by volume of hydrocarbons. The law has, however, become inoperative because users of the Carburant National are not satisfied with it, and it entails a considerable loss to the state.

Recovery in the alcohol industry in Germany awaits a restoration of the potato production to something like pre-war standards, when about 75% of the alcohol made was distilled from potatoes, of which 2,500,000 tons, unsuitable for other purposes, were utilized,

producing an average of 77,000,000 gallons annually. The price which alcohol manufacturers may offer for potatoes is limited by the Government in the interest of conserving the potato crop for human and animal consumption. The national liquid fuel in Germany, "Monopolin," is composed of 45% petrol, 45% alcohol, and 10% benzol.

In the Hawaiian Islands the surplus of molasses is used to some extent for the production of alcohol for domestic purposes and for power. In Japan there are one or two motor fuels of which alcohol is an ingredient to about 50%. There are three plants in the Philippines for the manufacture of alcohol, and two liquid fuels are produced from it. One is a mixture of alcohol and ether, the other a mixture of alcohol and petrol. In Sweden a mixture of 25 parts of alcohol, obtained from sulphite lyes, and 70 parts of benzol is being sold under the name of "Bentyl" for use in motors. There are several distilleries in Norway capable of supplying alcohol from sulphite lyes up to 25% of the motor fuel requirements. (R. Ro.; F. L. N.)

INDUSTRIAL ALCOHOL IN THE UNITED STATES

The principle of taxing and regulating alcoholic beverages is fundamental in all civilized countries, and this principle was applied to alcohol itself until industrial needs achieved special legislation, granting tax-free alcohol for industrial purposes.

On Dec. 17, 1897, a joint committee of Congress said "The uses of alcohol, other than as a beverage, are more largely and widely extended than is generally supposed. But while the use of alcohol as a beverage is purely voluntary its employment for all other purposes is legitimate and necessary. No article entering into the manufacture or the arts, whether of domestic or foreign production, performs more beneficial functions. There is scarcely a manufacturer in the country who does not use alcohol in the production of his goods to a greater or less extent."

All ethyl alcohol previous to 1906 carried a heavy revenue tax that effectively restrained any increase in its industrial use. But in 1906 the Tax Free Industrial and Denatured Alcohol Act was passed by Congress, and the development of industrial alcohol manufacture may be said to date from the passage of this Act, by which the tax on alcohol intended "for use in the arts and industries and for fuel, light and power" was lifted, provided it had been denatured and rendered unsuitable for use as a beverage.

THE PLANT OF THE U.S. INDUSTRIAL ALCOHOL CO. AT BALTIMORE

This plant, with its full rail and water facilities, occupies an admirable position for the manufacture of industrial alcohol. In the foreground are the huge storage tanks for molasses; at the right centre are the molasses tank steamers, with one of them unloading her cargo. The fermenting building, power plant and still houses are on the upper left.

Supplemental laws were later enacted, with the result that the manufacture, distribution, sale and use of industrial alcohol has become vital. The advent of prohibition presented an added, and perhaps more potent, reason why the taxable pure ethyl alcohol should be replaced, as far as possible, with tax-free denatured alcohol, and Section 10, Title III, of the National Prohibition Act provides for denaturing plants at which ethyl alcohol could be lawfully denatured "by the admixture of such denaturing materials as shall render the alcohol or any compound in which it is authorized to be used unfit for use as an intoxicating beverage."

Under the provisions of Title III, the commissioner of Internal revenue is empowered to promulgate regulations covering the manufacture, distribution, sale and use of industrial alcohol.

"Black strap" molasses, a by-product of sugar-cane refining and once considered as a useless waste product, is at present the principal raw material for about 90% of all industrial alcohol made in the United States, 270,000,000 gal. having been used during the year ending June 30, 1926. The remaining 10% used in alcohol production is composed principally of sugar, raisins, corn, rye, malt, rice, hops and other miscellaneous materials. The bulk of raw molasses used comes from Cuba, although a small supply is furnished by other islands of the West Indies, Hawaii and the cane-growing regions of the United States.

The importation of raw molasses has increased from 25,000,000 gal. for the year ended June 30, 1904, to 270,000,000 gal. for the year ended June 30, 1926. Louisiana is the chief producing centre of the industry, followed by Illinois, Maryland and Pennsylvania, with a few plants situated in other parts of the country.

Completely Denatured Alcohol.—This is ethyl alcohol which has been rendered violently poisonous by the addition of denaturants according to a limited number of formulae prescribed by the U.S. internal revenue bureau, and so made entirely unfit for beverage purposes, as well as injurious if used externally. It may be bought and sold without keeping records or making reports to the internal revenue bureau, but persons dealing in, storing or using such alcohol in quantities exceeding 100 lb. or drums during a period of 30 days must keep such commercial records as will enable any Government officer to trace the receipt and disposal of such alcohol.

Of the formulae prescribed by the internal revenue bureau for completely denatured alcohol the following, "No. 1," is chiefly used:

FORMULA NO. 1

100 parts by volume ethyl alcohol, not less than 160% proof.
10 parts by volume approved wood alcohol.
0.5 parts by volume approved benzine (kerosene).

Specially Denatured Alcohol.—This is designed for distribution to approved manufactures, under regulations, protected by a bond to guarantee the faithful performance of the conditions stipulated by the Government. In such alcohol only those denaturants are used which will not materially interfere with the special manufacturing use to which the alcohol is to be put. There are about 100 formulae for specially denatured alcohol which have been authorized by the Government for over 400 different uses.

Industrial Uses of Alcohol.—Ethyl alcohol is the most widely used solvent next to water, and after it has been properly denatured, enters directly or indirectly into the manufacture of varnishes, paints, artificial leather, anti-freeze solutions, explosives, moving picture film, inks, tobacco, lacquers, anaesthetics, antiseptics and hundreds of other products.

PRODUCTION OF INDUSTRIAL ALCOHOL FOR SPECIFIED YEARS

Fiscal years	Denaturing plants	Completely denatured	Specially denatured	Total
		(wine, gals.)		
1907 . . .	8	1,397,861	382,415	1,780,276
1914 . . .	25	5,213,130	5,191,846	10,404,976
1918 . . .	49	10,328,455	39,834,561	50,163,016
1919 . . .	45	9,976,721	28,294,219	38,270,940
1920 . . .	52	13,528,403	15,307,947	28,836,350
1921 . . .	67	12,392,595	9,996,230	22,388,825
1922 . . .	77	16,193,524	17,152,224	33,345,748
1923 . . .	76	27,128,230	30,436,913	57,565,143
1924 . . .	83	34,602,004	33,085,292	67,687,296
1925 . . .	91	46,983,970	34,824,303	81,808,273
1926 . . .	97	65,881,442	39,494,444	105,375,886
1927 . . .	94	56,093,748	39,354,933	95,448,681

The post-war developments in the automobile industry have resulted in more than half the annual output of industrial alcohol being devoted to some phase of its manufacture or operation. Nearly 40,000,000 gal. are used annually by manufacturers of solutions which prevent the freezing of water in automobile radiators. Lacquer, another enormous consumer of industrial alcohol,

is, because of its rapid drying qualities through evaporation of the alcohol (while paints and varnishes dry by a process of oxidation) and the ease with which it may be applied, rapidly superseding the use of oil paints and varnishes for the exterior finish of passenger cars. When dry it is inert and has a hard tough surface.

Ordinary alcohol contains 5% water and it was not until 1926-27 that absolute or anhydrous alcohol was developed to such a degree that it could be manufactured in tank car quantities at less than \$1.00 per gal. The development of absolute alcohol is considered one of the great triumphs of the chemical industry.

The United States Navy and the United States post office have found that gasoline when mixed with absolute alcohol produces a superior aeroplane fuel. (J. C. McG.)

ALCOHOLISM: see DRUNKENNESS.

ALCOHOLOMETRY: see ALCOHOL, *Determination*.

ALCOHOLS, in organic chemistry, a class of compounds of which ethyl alcohol (see ALCOHOL) is perhaps the most common member derived from paraffinoid and non-aromatic hydrocarbons by the replacement of one or more hydrogen atoms by hydroxyl groups. This definition excludes such compounds as the phenol (hydroxy derivatives of benzene, naphthalene and other aromatic hydrocarbons) which are more acidic than the true alcohols.

Alcohols are classified on two distinct principles, one depending upon the number of hydroxyl groups present, the other on the nature of the remaining groups attached to the carbon atom which carries the hydroxyl group. Monohydric alcohols contain only one hydroxyl group; dihydric, two known as glycols; trihydric, three known as glycerols; and so on (see CHEMISTRY: *Organic*).

The second principle leads to alcohols of three distinct types, known as primary, secondary and tertiary (H. Kolbe, 1860). The genesis of these types may be readily understood by considering the relation which exists between the alcohols and the parent hydrocarbon. In methane, CH₄, the hydrogen atoms are of equal value, and hence only one monohydric alcohol, viz., CH₃OH, can be derived from it. This compound, methyl alcohol (carbinol), is the simplest primary alcohol, and it is characterized by the grouping ·CH₂OH. Ethane, C₂H₆, in a similar manner, can only give rise to one alcohol, namely ethyl alcohol or methylcarbinol, CH₃CH₂OH, which is also primary. Propane, CH₃CH₂CH₃, can give rise to two alcohols—a primary alcohol, CH₃CH₂CH₂OH (normal propyl alcohol or ethylcarbinol), formed by replacing a hydrogen atom attached to a terminal carbon atom, and a secondary alcohol, CH₃CH(OH)CH₃ (isopropyl alcohol or dimethylcarbinol), when the substitution is effected on the middle carbon atom. The grouping CH-OH characterizes the secondary alcohols; isopropyl alcohol is the simplest member of this class. Butane, C₄H₁₀, exists in the two isomeric forms—normal butane, CH₃CH₂CH₂CH₃, and isobutane, CH(CH₃)₃. Each of these hydrocarbons gives rise to two alcohols: *n*-butane gives a primary and a secondary; and isobutane a primary, when the substitution takes place in one of the methyl groups, and a tertiary, when the hydrogen atom of the ·CH group is substituted. Tertiary alcohols are thus seen to be characterized by the group ·C-OH, in which the residual valencies of the carbon atom are attached to alkyl groups. The three types of alcohol may be formulated as follows:—R·CH₂·OH (Primary); (R₁R₂) CH-OH (Secondary); (R₁R₂R₃) C-OH (Tertiary).

Properties.—The alcohols are neutral in reaction, and the lower members possess the property of entering into combination with salts, in which the alcohol plays the rôle of water of crystallization. Sodium or potassium dissolves in the alcohols with the formation of alcoholates (alkyloxides), the hydrogen of the hydroxyl group being replaced by the metal. With strong acids water is split off and esters are formed. The halide esters of the paraffin alcohols, formed by heating the alcohols with the halogen acids, are more conveniently prepared by the action of the phosphorous halide on the alcohol. Energetic dehydration gives rise to olefinic hydrocarbons, but under certain conditions ethers (see ETHER) are obtained.

The physical properties of the alcohols exhibit a gradation with the increase of molecular weight. The lower members are

colourless mobile liquids, readily soluble in water and exhibiting a characteristic odour and taste. The solubility decreases as the carbon content rises. The normal alcohols containing 1 to 16 carbon atoms are liquids at the ordinary temperatures; the higher members are crystalline, odourless and tasteless solids, closely resembling the fats in appearance. The boiling points of the normal alcohols increase regularly about 19° for each CH_2 increment; this is characteristic of all homologous series of organic compounds. Of the primary, secondary and tertiary alcohols having the same empirical formula, the primary have the highest, and the tertiary the lowest boiling point; this is in accordance with the fairly general rule that a gain in symmetry is attended by a fall in the boiling point.

Distinctive Tests for Primary, Secondary and Tertiary Alcohols.—Many reactions serve to distinguish these three types of alcohol. Of chief importance is their behaviour on oxidation. The primary alcohols are first oxidized to aldehydes (*q.v.*), which, on further oxidation, yield acids containing the same number of carbon atoms as in the original alcohol. Secondary alcohols yield ketones (*q.v.*), which are subsequently oxidized to a mixture of two acids. Tertiary alcohols yield neither aldehydes nor ketones, but a mixture of two or more acids. Another method is based upon the different behaviour of the corresponding nitro-alkyl with nitrous acid. The alcohol is first acted upon with phosphorus and iodine, and the resulting alkyl iodide is treated with silver nitrite, which gives the corresponding nitro-alkyl. The nitro-alkyl is then treated with potassium nitrite dissolved in concentrated potash, and sulphuric acid is added. By this treatment the primary nitro-alkyl yields a nitrolic acid, the potassium salt of which forms an intense red solution; the secondary nitro-alkyl forms a pseudo-nitrole which gives an intense blue solution, while the tertiary compound does not react with nitrous acid. The reactions outlined above may be thus represented:—

By heating to the boiling point of naphthalene (218°) tertiary alcohols are decomposed, while heating to the boiling point of anthracene (360°) suffices to decompose secondary alcohols, the primary remaining unaffected. These changes, which can be followed out by determinations of the vapour density, provide a method for characterizing alcohols.

Preparation.—Monohydric alcohols may be readily prepared from the corresponding alkyl halide by the action of moist silver oxide (which behaves as silver hydroxide); by the saponification of their esters; or by the reduction of polyhydric alcohols with hydriodic acid, and the subsequent conversion of the resulting alkyl iodide into the alcohol by moist silver oxide. Primary alcohols are obtained by decomposing their sulphuric acid esters (from sulphuric acid and the olefines) with boiling water; by the action of nitrous acid on primary amines; or by the reduction of aldehydes, acid chlorides or acid anhydrides. Secondary alcohols result from the reduction of ketones; and from the reaction of zinc alkyls on aldehydes or formic acid esters.

Tertiary alcohols were first synthesized by A. Butlerow in 1864, by reacting with a zinc alkyl (methyl or ethyl) on an acid chlo-

ride; an addition compound was first formed, which decomposed with water to give a ketone. When, however, a second molecule of a zinc alkyl was allowed to react, a compound was formed which gave a tertiary alcohol when decomposed with water.

It is interesting to note that, whereas zinc methyl and ethyl give tertiary alcohols, zinc propyl only gives secondary alcohols. The Grignard reaction (*q.v.*) affords a means of synthesizing the three classes of monohydric alcohols, the process being based on the addition of a Grignard reagent to a carbonyl group. When added to formaldehyde, a primary alcohol is obtained. With any other aldehyde a secondary alcohol is produced, whereas with a ketone the product is a tertiary alcohol.

The following monohydric alcohols receive special treatment under their own headings:—ALCOHOL (ETHYL), ALLYL ALCOHOL, AMYL ALCOHOLS, BENZYL ALCOHOL, BUTYL ALCOHOLS, METHYL ALCOHOL and PROPYL ALCOHOLS.

ALCOTT, AMOS BRONSON (1799–1888), American educationalist and writer, was born of farming stock in Wolcott

THE CONCORD HOME OF AMOS BRONSON ALCOTT, NEW ENGLAND TRANSCENDENTALIST WHOM CARLYLE CALLED "THE POTATO QUIXOTE"

(Conn.), Nov. 29, 1799. Extravagant pedlar, visionary school-teacher, peripatetic philosopher, Bronson Alcott gives the lie to all theories of Yankee shrewdness and thrift. "A venerable Don Quixote," as Carlyle termed him, "all bent on saving the world by a return to acorns and the golden age," he was ridiculed by the majority of his contemporaries, including Lowell in *A Fable for Critics* and some of the Transcendentalists. But Emerson, although recognizing his limitations, remained a staunch friend; and educators have long since adopted many of the theories of this "American Pestalozzi." His truth to his ideals seems to have involved more suffering for his wife, Abigail May, and his four daughters than for himself. School after school had to be given up, in part because of the conservatism of his patrons, in part because of harsh criticism such as that of Harriet Martineau, and in part because of too rigid adherence to his principles, as when he refused to dismiss the little negro girl who disrupted his Boston group. Indeed, Alcott was too visionary even to be a satisfactory day-labourer. In later life his western lecturing trips were made pleasant and financially profitable through his "riding in Louisa's chariot" and being known as the "grandfather of *Little Women*"; and his long-cherished dream of presiding over a Concord Summer School of Philosophy and Literature was fulfilled. He had early received some recognition in England. He died on March 4, 1888, just before his celebrated daughter.

Since in Alcott's lifetime his writings were recognizably inferior to his informal lectures or "conversations," it is natural that few should search to-day for the vignettes of contemporaries and the nuggets of wisdom scattered through his "Orphic Sayings" in the *Dial*, his *Tablets* (1868), *Concord Days* (1872) and *Table Talk* (1877). The poem *New Connecticut* (1887) and some of the *Sonnets and Canzonets* (1882) are of autobiographic value; and his *Observations on the Principles and Methods of Infant Instruction* (1830), together with Elizabeth Peabody's transcripts of his classroom procedure in *Record of a School* (1835), etc., reveal his educational innovations. *A. Bronson Alcott: His Life and Philosophy* (1893), by F. B. Sanborn and W. T. Harris, draws largely upon Alcott's diaries, and *Bronson Alcott's Fruitlands* (1915), an interesting compilation by Clara E. Sears, illuminates his unfortunate experiment in Communistic plain living and high thinking. See also Honoré W. Morrow, *The Father of Little Women* (1927).

ALCOTT, LOUISA MAY (1832–1888), American author, was born in Germantown, now part of Philadelphia (Pa.), Nov. 29, 1832. Like her mother, she felt deeply the family trials and privations caused by the impracticality of her father, Amos Bronson Alcott. In later life she defined a philosopher as "a man up in a balloon, with his family and friends holding the ropes

which confine him to earth and trying to haul him down." When she was still a young girl her journal reflected her determination to earn money and make her family comfortable. Fortunately the Alcotts' wandering life had allowed her plenty of time out of doors, so that a strong body was built up for the active brain, and, as she herself put it, nature gave her a vital sense of God's presence "never to change through forty years of life's vicissitudes, but to grow stronger for the sharp discipline of poverty and pain, sorrow and success." She started her bread-earning career early as a dolls' dressmaker, and in a few years was putting her hand to anything that would bring in money to purchase necessities and pay off debts for her family—teaching, sewing, even, for a short period, domestic service. "Pot-boilers" at this period brought in five or ten dollars apiece; of a wild, sensational type, they worked off her steam and perhaps gave some facility in writing. Their nature may be judged from "The Baron's Gloves" and "A Whisper in the Dark," which have been included in her collected works. In 1860 50 dollars for an *Atlantic* story seemed like wealth and fame indeed. Her first book was *Flower Fables* (1854), tales originally written for R. W. Emerson's little daughter Ellen; but she attained widespread celebrity only after the publication of her *Hospital Sketches*, serially in the *Commonwealth* and in book form in 1863 (republished with additions, 1869). These were a revision of her letters to her family during her period as nurse in the Union hospital at Georgetown, D.C. Her six weeks there in 1862-63 resulted not only in fame but also unfortunately in shattered health, and this, combined with her incessant overwork, finally caused her death, in Boston, March 6, 1888, two days after her father's death.

Of her life the best record is her own. As the "Jo" of *Little Women* (1868), the most popular girls' book ever written in America, she will always live in the hearts of her readers. Although this is probably the most autobiographical of her books, other of her experiences in Boston, Concord and abroad are reflected in *Jo's Boys* (1886); *An Old-Fashioned Girl* (1870); *Shawl Straps* (1872), one of the series *Aunt Jo's Scrap Bag* (6 vol., 1871-79); *Moods* (1864), a much revised novel, and L. Alcott's favourite; *Work* (1873); and many of her shorter pieces. *Little Men* (1871) describes her nephews, children of her older sister, Anna; *Lulu's Library* (3 vol., 1885-89) is named after the little niece whom the artist sister, May, when dying bequeathed to her; and *Jack and Jill* (1880) makes use of the Concord young people.

Miss Alcott's most enduring place is due to the cheeriness and wholesomeness of her pictures of boy and girl life. Her novels *Moods*, *Work* and *A Modern Mephistopheles* (1877) in the "No Name" series are experimental in technique; and even her juvenile books show the inequalities attendant upon her haste in production and her ill health. In early life poverty was responsible for her steady output; in later life nervous restlessness and perhaps excessive generosity caused her to feel the necessity of supplying all demands upon her. After only one article on Ralph Waldo Emerson, long her idol and her family's truest friend, do we find not the dollar sign in her journal but "a labour of love." In any estimate, however, her lavishness in giving not only of her money but also of her personal service to relatives, friends and strangers alike and her ardour in the causes of abolition and woman's suffrage must be considered. Through several generations she has held her place among America's most popular writers for children.

By far the best biography is Ednah D. Cheney's *Louisa May Alcott: Her Life, Letters, and Journals* (Boston, 1889), which contains Miss Alcott's early records and also her later annotations. Copious use is made of it by Belle Moses in *Louisa May Alcott, Dreamer and Worker* (1909), and by the writers of numerous shorter sketches.

ALCOY, south-eastern Spain, province of Alicante, on the small river Sérpis, and at the terminus of a branch of the Barcelona-Valencia-Alicante line. Pop. (1920) 36,463. Alcoy is built on high ground at the entrance to a gorge. It is a thriving industrial town, with manufactures of linen, woollen goods, agricultural machinery, almond confections and paper, especially cigarette paper. The Salta de las Aguas, a waterfall, provides ample industrial power. For an account of the festival of St. George of

Alcoy, see J. A. Llobet y Valloera, *Apuntes historicos acerca de las fiestas que celebra cada año la ciudad de Alcoy a su patron San Jorge* (Alcoy, 1853).

ALCUIN (ALCHUINE), ecclesiastic and man of learning in the 8th century, who liked to be called by the Latin name of ALBINUS, and at the Academy of the palace of Charlemagne took the surname of FLACCUS, was born at Eboracum (York) in 735. Alcuin is important in the European history of his time, because he carried the learning of the British Isles to the court of Charlemagne and so to western Europe. He was educated at the cathedral school of York, under Aelbert, with whom he went to Rome in search of manuscripts. When Aelbert was appointed archbishop of York in 766, Alcuin succeeded him as head of the episcopal school. He again went to Rome in 780, to fetch the *pallium* for Archbishop Eanbald, and at Parma met Charlemagne, who persuaded him to come to his court, and gave him the great abbeys of Ferrières and of Saint-Loup at Troyes. The king desired his help in the revival of learning among the Franks. From 781 to 790 Alcuin was Charlemagne's right hand in this enterprise. He had as pupils the king of the Franks, the members of his family and the young clerics attached to the palace chapel; he was the life and soul of the academy of the palace, and we have still, in the *Dialogue of Pepin* (son of Charlemagne) and *Alcuin*, a sample of the intellectual exercises in which they indulged. It was under his inspiration that Charles wrote his famous letter *de litteris colendis* (Boretius, *Capitularia*, i. p. 78), and he founded the palace library. In 790 Alcuin returned to his own country, but Charlemagne needed him to combat the Adoptionist heresy, which was making headway in the marches of Spain. At the Council of Frankfort in 794 Alcuin upheld the orthodox doctrine, and obtained the condemnation of the heresiarch, Felix of Urgel. After this victory he returned to his own land, but only for a brief period. Charlemagne gave him the great abbey of St. Martin at Tours, and there he passed his last years. Many students flocked to the abbey school; he had numerous manuscripts copied, the calligraphy of which is of extraordinary beauty (v. Léopold Delisle in the *Mémoires de l'Académie des Inscriptions*, vol. xxxii, 1st part, 1885). The script used was the Carolingian minuscule from which our own roman type derives. He wrote numerous letters to his friends in England, to Arno, bishop of Salzburg, and above all to Charlemagne. These letters, of which 311 are extant, are filled chiefly with pious meditations, but they form a mine of information as to the literary and social conditions of the time, and are the most reliable authority for the history of humanism in the Carolingian age. Others deal with astronomy, a favourite subject with the emperor. Alcuin died on May 19, 804.

Alcuin is the most prominent figure of the Carolingian Renaissance, in which have been distinguished three main periods: in the first of these, up to the arrival of Alcuin at the court, the Italians occupy the chief place; in the second, Alcuin and the Anglo-Saxons are dominant; in the third, which begins in 804, the influence of the Goth Theodulf is preponderant. Besides some graceful epistles in the style of Fortunatus, Alcuin wrote some long poems, and notably a whole history in verse of the church at York: *Versus de patribus, regibus et sanctis Eboracensis ecclesiae*. He wrote also manuals used in his educational work; a grammar and works on rhetoric and dialectics, written in the form of dialogues. He composed homilies, a treatise *de Fide Trinitatis*, etc., and is said to have revised the text of the Latin Bible.

The complete works of Alcuin have been edited by Froben: *Alcuini opera* (Regensburg, 1777). This edition is reproduced in Migne's *Patrolog. lat.* vols. c. and ci. The letters have been published by Jaffé and Dümmler in Jaffé's *Bibliotheca rerum germanicarum*, vol. vi., p. 132-897 (1873). E. Dümmler also published an authoritative edition, *Epistolae aevi Carolini*, vol. ii., p. 1-481, in the *Monumenta Germaniae*, and edited the poems in the same collection: *Poetae latini aevi Carolini*, vol. i., p. 169-341.

ALCYONE or **HALCYONE**, in Greek mythology, daughter of Aeolus and wife of Ceyx. For their insolence in calling themselves Zeus and Hera, Alcyone was changed into a diver, Ceyx into a kingfisher. In another story, Ceyx was drowned and his body cast on the shore. His wife found the body, and the gods, out of compassion, changed both into kingfishers. The winds ceased to blow during their brooding-time, hence the expression "halcyon days," used in ancient and modern times to denote a period of calm and tranquillity (Ovid, *Metam.*, xi. 410 et seq.).

ALDABRA ISLANDS, in the Indian ocean, part of the British colony of Seychelles, in $9^{\circ} 30' S.$, $46^{\circ} E.$, 265m. N.W. of the northern point of Madagascar and 690m. S.W. of Mahé, in the Seychelles. The islands are an oval atoll some 40m. in circumference and about $1\frac{1}{2}$ m. broad, enclosing a shallow lagoon. Channels divide the ring into four islands, which rise from 20 to 80ft. above the sea. Grande Terre or South island forms three-fifths of the circumference. The other islands are West island or Île Picard, Polymnie, Middle island, and several islets (e.g., Île Michel) in the lagoon. The total land area is estimated at about 60sq.m. Pop. (1906) 127. The external cliffs of coral and limestone are in places replaced by sandy beaches and sandhills. There is very little soil. Dense scrub covers most of the land, but the lagoon shore is bounded by mangrove swamps. The flora and fauna are of great interest. The gigantic land tortoise (*Testudo elephantina*) is now carefully preserved. Peculiar birds include a rail (*Dryolimnas aldabranus*), an ibis (*Ibis abbottii*) and a dove (*Alectroenas sganzini*). Oysters and large crabs occur, and a small mussel is found in enormous numbers. The flora includes mangroves, *Rubiaceae*, *Sapotaceae* and other forms requiring more than pure coralline material for their growth. The predominant species are Madagascar plants and birds, carried by currents and winds. There are few endemic species of plants. Aldabra seems to have been built up on the sunken surface of the old Gondwana continent by a deposit, in the opinion of Prof. A. Voeltzkow, of foraminifer remains (mostly coccoliths and rhabdoliths), and it has never been joined to any other land (Stanley Gardiner). Dupont states that at Aldabra the coral foundation is totally above water. The coral limestone of the atoll is vitrified and gives out a ringing sound when struck or simply walked on. The coral is generally reddish, but runs from light yellow to chocolate-brown.

Aldabra was visited by the Portuguese in 1511 but was already known to the Arabs, who gave the name. In the 18th century the islets became dependencies of the French establishments at Bourbon (Réunion). In 1810 with Mauritius, Bourbon (for a time), the Seychelles and other islands, Aldabra became British. The inhabitants are emigrants from the Seychelles. Goats are bred and coco-nuts cultivated, but fishing is the chief industry. With other outlying islands Aldabra is held under lease from the Seychelles Government, the lessees having exclusive trading privileges.

See R. Dupont, *Report on a Visit of Investigation to . . . the Aldabra Group of the Seychelles Islands* (Seychelles, 1907); Dr. Abbott in *Proceedings*, United States National Museum (Washington, 1894); A. Voeltzkow in *Abh. der Senckenbergischen Naturforschenden Ges.* vol. xxvi. pt. iv. (1901); J. S. Gardiner, "The Indian Ocean," *Geo. Journ.* (Oct. 1906).

ALDANOV, MARK ALEXANDROVICH (1889–), Russian novelist and publicist, also known as Landau-Aldanov, was born at Kiev. His most considerable work is a trilogy, *The Thinker*, in which the French Revolution is treated with learning, understanding and philosophy. He also discusses in *Armageddon* (1915) the World War, but here shows himself more elegant than precise.

ALDBOROUGH, a village in the West Riding of Yorkshire, England, 16m. W.N.W. of York. Pop. (1921), 424. There are evidences of settlement from early times, the site being known to the Romans as *Isurium Brigantum*.

ALDEBARAN, α Tauri, is the brightest star in the constellation Taurus (*q.v.*). It is reddish in colour and radiates about 74 times as much light as does the sun. Its magnitude is 1.1.

ALDEBURGH (ALDBOROUGH), municipal borough on the coast of Suffolk, England, the terminus of a branch of the London and North Eastern railway, $99\frac{1}{2}$ m. N.E. of London. Population (1931) 2,480. The district is exposed, but a fine stretch of sand fringes Aldeburgh bay. To the west the river Alde broadens as if into an estuary, but its outflow is prevented by the sand, and it runs south for nearly 10m. parallel with the shore. The sand banks have arrested the encroachments of the sea, which submerged a former site of Aldeburgh.

Aldeburgh (Aldburc) takes its name from the river Alde. There is no pre-Conquest record but at the Domesday survey most of the land was held by Robert Malet, a Norman. In 1155 the manor was granted to the abbey of St. John of Colchester and later to Cardinal Wolsey. In 1567 a Saturday market was granted. In the 16th century Aldeburgh was a place of considerable commercial importance. The earliest charter is that of 1529. In 1548 it was made a free borough, with a charter of incorporation and a market on Wednesday. Later charters were granted in 1553, 1558 and 1567, by James I. (who granted two annual fairs) in 1606, and by Charles I., in 1631 and 1637. The fairs and markets became so unimportant that they were discontinued about the middle of the 19th century. The town returned two members to parliament in 1572, and continued to do so until the Reform Act of 1832. Frequent disastrous incursions of the sea reduced Aldeburgh to a mere fishing village, but it is now a golfing centre. There are coastguard and lifeboat stations. A small Moot Hall of the 16th century is used for corporation meetings. Slaughden quay on the Alde admits small vessels, and herring and lobster fishing are carried on. Aldeburgh is governed by a mayor, four aldermen and 12 councillors. Area 1,663 acres. It is included in the Woodbridge division of the parliamentary county of east Suffolk.

ALDEGREVER or **ALDEGRAF, HEINRICH** (1502–1558), German painter and engraver, was born at Paderborn, from whence he removed in early life to Soest, where he died. From the close resemblance of his style to that of Albrecht Dürer he has sometimes been called the Albert of Westphalia. There is a good collection of his engravings in the British Museum. Specimens of his painting are exceedingly rare. Five pictures are in Continental galleries, but the genuineness of the works in the Vienna and Munich collections attributed to him is at least doubtful, the only unchallenged example being a portrait of Engelbert Therlaen (1551) in the Berlin Museum.

ALDEHYDES, an important class of chemical compounds having the general formula $R \cdot CHO$, where R is an alkyl (aliphatic) or aryl (aromatic) radical. The name is derived from *alcohol dehydrogenatus* (J. Liebig), indicating that these compounds may be obtained from primary alcohols by removal of hydrogen: $RCH_2 \cdot OH - 2H = R \cdot CHO$.

The group CHO which is to be found in all aldehydes contains the most active form of the carbonyl radical, CO, known to chemists, and it is to the intense reactivity of this radical that the aldehydes owe their importance as organic synthetic agents both in nature and in the chemical laboratory.

Aldehydes are generally named specifically after the acids into which they are converted by oxidation, thus formaldehyde, acetaldehyde and benzaldehyde furnish formic, acetic and benzoic acids, respectively. In more complicated cases, the termination *al* is employed to denote aldehydic functions, according to the Geneva convention of chemists, thus geranial, the aldehyde of lemon-grass oil, is the oxidation product of the alcohol, geraniol, contained in geranium oil (see TERPENES).

Many aldehydes are known to chemistry, some being produced artificially, whereas numerous others are found in the vegetable kingdom either free (e.g., cinnamaldehyde in cinnamon oil) or combined in certain glucosides (e.g., benzaldehyde in amygdalin, see GLUCOSIDES).

Properties of Typical Aldehydes.—Formaldehyde, $H \cdot COH$, at once the simplest of the aldehydes and the prototype of the carbohydrates, $C(H_2O)$, is a gas at the ordinary temperature (b.p. $-21^{\circ} C.$) and is prepared by passing the vapour of methyl alcohol and air over heated copper gauze. The gaseous aldehyde is collected in water to form a 30–40% solution known commercially

as Formalin (*q.v.*). This solution on concentration yields a white solid polymeride known as paraformaldehyde $(\text{CH}_2\text{O})_3$. When, however, the gaseous formaldehyde is cooled, it polymerizes to a crystalline modification termed trioxymethylene, $(\text{CH}_2\text{O})_3$. These polymeric forms are dissociated on heating into the gaseous monomeric formaldehyde $(\text{CH}_2\text{O})_3 \rightleftharpoons 3\text{CH}_2\text{O}$.

Acetaldehyde, prepared by oxidation of ethyl alcohol and by direct synthesis from carbon monoxide and hydrogen (*v. infra*), is a volatile liquid boiling at 21°C . and miscible in all proportions with water. It is readily polymerized catalytically by traces of zinc chloride, hydrochloric acid, etc., at the ordinary temperature to para-acetaldehyde or "paraldehyde" $(\text{C}_2\text{H}_4\text{O})_3$, a liquid boiling at 124° and only moderately soluble in water. Paraldehyde, employed medicinally as a sedative without action on the heart, is administered intravenously as an anaesthetic or hypnotic. When the foregoing polymerization of acetaldehyde takes place in a freezing mixture, metaldehyde (meta-acetaldehyde) is produced as a white crystalline solid subliming at $112\text{--}115^\circ\text{C}$. This substance is insoluble in water and when heated in a sealed tube at 100° is reconverted into the monomeric form. Metaldehyde, which is produced commercially, has been recommended as a smokeless fuel, replacing the spirit lamp for toilet purposes.

The simultaneous chlorination and oxidation of ethyl alcohol leads to trichloroacetaldehyde which in its hydrated state is the well-known drug Chloral Hydrate (*q.v.*).

Aldolisation.—The condensation of formaldehyde and acetaldehyde into their polymeric forms is a chemical change which is readily reversible by thermal dissociation. But in addition to this reversible change, aldehydes have the capacity for undergoing a polymerization in which the carbon atoms of separate molecules become directly attached so that the process becomes irreversible. This mode of polymerization, which is termed aldolisation, undoubtedly plays an important part in the building up of carbon compounds in the green plant, following on the assimilation of carbon dioxide by photosynthesis. Aldol (β -hydroxybutaldehyde) is formed by a polymerization of two molecules of acetaldehyde:

By loss of water aldol passes into the unsaturated crotonaldehyde, $\text{CH}_3\text{CH}:\text{CH}\cdot\text{CHO}$.

This adding of carbon to carbon occurs in a marked degree in the case of formaldehyde and the process is instrumental in the vegetable kingdom in the building up of complex carbohydrates (sugars, starches, cellulose) from formaldehyde, the simplest carbohydrate, $\text{C}(\text{H}_2\text{O})$. The aldolisation of formaldehyde has been effected in the laboratory; a sixfold polymerization in the presence of magnesia (Loew) furnished α - and β -acroses, two synthetic sugars which have since been identified as inactive fructose and inactive sorbose respectively.

Resinification.—Acetaldehyde and certain of its homologues are converted into resins under the influence of alkalis. Acrolein, $\text{CH}_2:\text{CH}\cdot\text{COH}$, the simplest of the unsaturated aldehydes, is obtained by abstraction of water from glycerine by the agency of alkali bisulphates and phosphoric or boric acid. It is a colourless liquid boiling at 52.4°C . with a disagreeable, tear-exciting odour. In the presence of traces of acids, it readily undergoes polymerization to form a solid resinous material, metacrolein (*see RESINS, SYNTHETIC*). Acrolein forms a dibromide from which E. Fischer by the action of baryta water obtained the synthetic sugars, α - and β -acroses.

Benzaldehyde, the most important commercially of the aromatic aldehydes, is usually made from the chlorinated derivatives of toluene. Benzyl chloride, $\text{C}_6\text{H}_5\text{CH}_2\text{Cl}$, heated with aqueous lead or cupric nitrate furnishes benzaldehyde, which is also prepared by heating benzal or benzylidene chloride, $\text{C}_6\text{H}_5\text{CHCl}_2$ with milk of lime. As prepared by either method, benzaldehyde is contaminated with traces of chlorinated benzaldehydes, and when chlorine-free benzaldehyde is needed it is prepared by the direct oxidation of toluene by chemical means (manganese dioxide and sulphuric acid) or by electrolytic means (an acetone-sulphuric acid solution with platinum electrode).

Benzaldehyde is a colourless, highly refractive liquid boiling at

$179\text{--}180^\circ$ with the characteristic odour of oil of bitter almonds of which oil it is the essential constituent, being derived from the hydrolysis of the glucoside, amygdalin, present in the almond. It readily absorbs oxygen from the air, becoming oxidized to benzoic acid. With aqueous caustic alkalis it undergoes the Cannizzaro reaction, $2\text{C}_6\text{H}_5\text{CHO} = \text{C}_6\text{H}_5\text{CH}_2\text{OH} + \text{C}_6\text{H}_5\text{CO}_2\text{H}$, yielding molecular proportions of benzyl alcohol and benzoic acid. With alcoholic potassium cyanide, it gives benzoin, $\text{C}_6\text{H}_5\text{CH}(\text{OH})\cdot\text{CO}\cdot\text{C}_6\text{H}_5$. Benzaldehyde is also an important intermediate in the production of colouring matters (*see DYES, SYNTHETIC, and MALACHITE*). When condensed with acetic anhydride and dry sodium acetate, it yields cinnamic acid, whereas cinnamaldehyde arises from a condensation between benzaldehyde and acetaldehyde in the presence of sodium ethoxide.

Furfuraldehyde (furfural), $\begin{array}{c} \text{O} - \text{CH}:\text{CH} \\ | \\ \text{C}(\text{CHO})\text{:CH} \end{array}$, is an example of a non-

aromatic cyclic aldehyde (*see CHEMISTRY: Organic, Heterocyclic*), formerly obtained by the hydrolysis of bran with dilute mineral acid and now manufactured in the U.S.A. by the action of steam and dilute acid on oat hulls and corn cobs and stalks contained in large digestors. The volatile furfuraldehyde (b.p. $160\text{--}162^\circ$) is isolated and purified by fractional distillation.

GENERAL METHODS OF PREPARATION

1. *Direct synthesis.* Arising from a study of chemical reactions under high pressure it has been found that when carbon monoxide and hydrogen are heated together at $360\text{--}380^\circ\text{C}$. under a pressure of 200 atmospheres in the presence of a mixed catalyst consisting of the oxides of cobalt, copper, manganese and zinc, a mixture of aliphatic aldehydes is produced among which formaldehyde, acetaldehyde, propionaldehyde and higher aldehydes have been identified (*see PRESSURE CHEMISTRY*).

2. *Action of ozone on olefines.* During an investigation of the action of ozone on various organic substances, C. D. Harries discovered that this active form of oxygen has a specific action on carbon compounds containing a double or ethylenic linkage. A molecular proportion of ozone attaches itself to the carbon atoms of the double linking forming an ozonide, which on treatment with water yields an aldehyde and an aldehyde peroxide, the latter becoming transformed into an acid. In the simplest case of ethylene this gas furnishes an explosive ozonide which subsequently gives rise to formaldehyde and formic acid,

A similar ozonization applied to more complex olefines has led to aldehydes which are otherwise prepared only with difficulty:

3. *Dehydrogenation of primary alcohols.* The primary alcohols may be dehydrogenated either thermally or by oxidation. In the former process the alcohol is passed over a heated metallic catalyst, preferably copper, although nickel, palladium or platinum or such oxides at vanadium pentoxide, V_2O_5 , may be employed. The oxidation of a primary alcohol to an aldehyde is generally effected by aqueous chromic acid (a solution of sodium bichromate and dilute sulphuric acid), but other oxidizing agents such as manganese dioxide and dilute sulphuric acid, or even atmospheric oxygen in presence of platinum black or bone black, may be employed.

4. *Synthesis through the Grignard reagent (*q.v.*).* A method of wide application for either aliphatic or aromatic aldehydes depends on the employment of the well-known Grignard reaction with ethyl formate, $\text{H}\cdot\text{CO}\cdot\text{OC}_2\text{H}_5$, an ester which it will be noticed contains the characteristic aldehydic group HCO . Thus when the formate is treated successively with magnesium ethyl iodide (the Grignard reagent from magnesium and ethyl iodide) and water, propionaldehyde is produced. A similar condensation on ethyl formate with magnesium phenyl bromide leads to benzaldehyde. In general the Grignard synthesis of aldehydes may be

represented by the following equations, when R is an organic radical and X a halogen (usually iodine or bromine):

5. *Thermal decomposition of α -hydroxycarboxylic acids.* This process, discovered by H. R. Le Sueur, has been worked out chiefly with the higher fatty acids. For example, stearic acid is converted successively into α -bromostearic and α -hydroxystearic acids. The latter acid, on heating at 270°C ., yields margaric aldehyde $\text{C}_{16}\text{H}_{33}\cdot\text{CHO}$ and formic acid. Incidentally this method forms a means of passing from common acids such as stearic and palmitic acids, which are readily obtained from natural sources, to acids such as margaric acid, $\text{C}_{16}\text{H}_{33}\cdot\text{COOH}$, which do not occur in nature.

6. The metallic formates contain the aldehydic group CHO and another general method for aldehydes depends on the heating together of an intimate mixture of calcium formate and the calcium salt of some other acid.

7. *Aromatic aldehydes from phenols.* A long-known process for the conversion of phenols into hydroxy-aryl-aldehydes is associated with the names of C. L. Reimer and F. Tiemann. It consists in treating the phenolic compound with chloroform in presence of dilute alkalis. With phenol itself the reaction proceeds as follows:

Two isomerides are produced, parahydroxybenzaldehyde and salicylaldehyde (orthohydroxybenzaldehyde). The latter isomeride occurs in the volatile oils of *Spiraea* and in the glucoside, salicin, of the willow.

8. *Syntheses by the aid of compounds containing bivalent carbon.* The two syntheses described under this heading, which are due to L. Gattermann, are, like those of the preceding section, applicable only to the aromatic series. The first depends on the use of carbon monoxide, this gas and hydrogen chloride being passed into a solution of an aromatic hydrocarbon in a dry solvent in the presence of cuprous and aluminium chlorides. In the case of toluene the condensation gives rise to *p*-tolualdehyde. In all probability the carbon monoxide absorbed by the cuprous chloride forms an intermediate compound, $\text{H}\cdot\text{COCl}$, with the hydrogen chloride and this nascent formyl chloride under the influence of aluminium chloride condenses with the hydrocarbon to give rise to the aldehyde:

The second Gattermann synthesis involves the use of hydrogen cyanide (anhydrous prussic acid), and since this reagent is now procurable on a manufacturing scale (*see PRUSSIC ACID*) the synthesis offers industrial possibilities. The aromatic substance, which may be a hydrocarbon or a phenol, is dissolved in a dry solvent containing anhydrous aluminium or zinc chloride and to this mixture hydrogen cyanide is added while hydrogen chloride is bubbled in to saturation when the two hydrides interact potentially as $\text{HN}\cdot\text{CHCl}$:

The aldehyde-imine thus formed as an intermediate product is hydrolysed when boiled with water into ammonia and the corresponding aldehyde, $\text{HO}\cdot\text{C}_6\text{H}_4\cdot\text{CHO}$. In this connection may be mentioned the synthesis of benzaldoxime by R. Scholl who treated benzene with mercury fulminate and partially hydrated aluminium chloride. The condensation may be regarded as occurring between fulminic acid (*q.v.*) and the hydrocarbon,

The three preceding reactions, including the two Gattermann syntheses and Scholl's condensation, represent the intervention of bivalent carbon as exemplified by carbon monoxide, CO, hydrogen cyanide, C:NH, and fulminic acid, C:NOH, respectively.

General Reactions of Aldehydes. The aldehydes combine additively with sodium hydrogen sulphite to furnish bisulphite compounds, $\text{R}\cdot\text{CH}(\text{OH})\cdot\text{SO}_3\text{Na}$. These compounds, being crystalliz-

able and easily hydrolysed by dilute acid, are frequently used in the purification of the aldehydes. Sodium hydrosulphite also interacts with aldehydes giving rise to compounds of the general formula $\text{R}\cdot\text{CH}(\text{OH})\cdot\text{SO}_2\text{Na}$. The formaldehyde compound is the important reducing agent, Rongalite, employed in calico printing for discharging the colour of dyes.

Aldehydes react with hydrogen cyanide to form cyanohydrins, $\text{R}\cdot\text{CH}(\text{OH})\cdot\text{CN}$, which are hydrolysable to α -hydroxycarboxylic acids containing one more carbon atom than the original aldehyde. Aldehydes combine with hydroxylamine to form oximes (*q.v.*), and with phenylhydrazine to form phenylhydrazones and with semicarbazide to crystallisable semicarbazones (*see CHEMISTRY, Organic*). Nascent hydrogen reduces aldehydes to primary alcohols, whereas with Grignard reagents they are converted into secondary alcohols. Formaldehyde condenses with aqueous ammonia to form hexamethylenetetramine, $\text{N}_4(\text{CH}_2)_6$, a valuable diuretic (hexamina B.P.) whereas the other aliphatic aldehydes combine with ethereal ammonia to give aldehyde-ammonias (hydroxyamines) of the type $\text{R}\cdot\text{CH}(\text{OH})\cdot\text{NH}_2$ from which the aldehyde can be regenerated by distillation with dilute acid. Aldehydes in general are characterized by the colour reaction of H. Schiff, this being the reddish-violet coloration developed with a solution of magenta or fuchsine which has been decolorized by sulphurous acid. (G. T. M.)

ALDEN, ISABELLA (MACDONALD) (1841–), American juvenile writer, was born in Rochester, N.Y., on Nov. 3, 1841. She was educated at Seneca collegiate institute in Ovid, N.Y., and at the Young Ladies' institute in Auburn, New York. In 1866 she married the Rev. Gustavus R. Alden. Under the pseudonym of "Pansy" she wrote a series of some 75 juvenile works, known as the "Pansy Books," and from 1873 to 1896 edited the juvenile periodical *Pansy*. In addition, she wrote *The Prince of Peace*, a life of Christ, and various volumes of fiction for adult readers. She also contributed extensively to religious journals.

ALDEN, JOHN (1599?–1687), one of the "Pilgrims" who in 1620 emigrated to America in the "Mayflower" and founded the Plymouth Colony. He was a settler of Duxbury (Mass.), where he lived for most of his life. From 1633 until 1675 he was an "assistant" to the governor of the Colony, frequently acting as governor. At the time of his death on Sept. 12, 1687, he was the last male survivor of the "Mayflower" company. He is remembered chiefly because of a popular legend, put into verse as *The Courtship of Miles Standish* by Henry W. Longfellow, concerning his courtship of Priscilla Mullins, whom he married in 1623, after having wooed her first for his friend, Miles Standish.

THE ARMORIAL BEARINGS OF ALDEN OF ENGLAND. ANCESTOR OF THE "MAYFLOWER" COLONIST

ALDER (*Alnus*), the name given to a group of shrubs and trees of the birch family (Betulaceae), comprising some 20 species distributed through the north Temperate zone and in the New World extending in the Andes to Chile. They are most readily distinguished from their allies the birches (*q.v.*) by the thick woody scales of the fruit (strobile), which persists on the branches long after the seeds and leaves have fallen.

The black alder (*A. glutinosa*), the most important Old World species, widespread in wet soils in Europe, Asia and North Africa and naturalized in Eastern North America, is the only alder native to Great Britain. It grows to a height of 75 ft., with smooth glossy leaves that are somewhat sticky when young. The soft brown wood, very durable in water, is used for piles and similar purposes. The speckled or hoary alder (*A. incana*), usually a shrub 8 ft. to 20 ft. high, found widely in Europe and northern Asia, is the common alder of swamps in the eastern United States and Canada. The green alder (*A. viridis*), 2 ft. to 10 ft. high, of Europe and Asia, occurs also in Eastern North America. The alders of the Rocky Mountain region and the Pacific coast often

become large trees. Among these are the red alder (*A. oregona*), the Sitka alder (*A. sinuata*), the white alder (*A. rhombifolia*). The red alder, which attains a height of 80 ft., with a trunk $3\frac{1}{2}$ ft. in diameter, is the most valuable; the soft but durable wood is used for furniture. In mountain regions alders are among the first woody plants to spring up in areas denuded by avalanches and in the rubble around the ends of receding glaciers.

Many alders are grown for ornament, especially varieties of the black and the speckled alder and also the Japanese alder (*A. japonica*), one of the largest and most beautiful species.

ALDER-FLY, the name given to neuropterous insects of the family *Sialidae* with long filamentous antennae and four large wings, of which the hind pair has the anal area folded fan-wise when at rest. They are sluggish insects found only near fresh water. The eggs are often very numerous and are laid in clusters on plants, etc., close to the water. The larvae are aquatic, are provided with biting jaws and breathe by seven or eight pairs of filamentous abdominal gills. The pupae are found in soil, moss, etc., and there is no cocoon. *Sialis lutaria* is the common alder-fly of Britain. In North America the genus *Corydalus* is remarkable for the great size of the jaws in the male and the insect has a wing-expanse of about 120 mm.: its larvae are called dobsons or hellgrammites by anglers who use them for bait.

ALDERMAN, a term implying the possession of an office of rank or dignity, and, in modern times, applied to an office-bearer in the municipal corporations and county councils of England and Wales, and in the municipal corporations of Ireland and the United States. Among the Anglo-Saxons, earls, governors of provinces and other persons of distinction received this title. Thus we read of the *aldermannus totius Angliæ*, who seems to have corresponded to the officer afterwards styled *capitalis justiciarius Angliæ*, or chief justice of England; the *aldermannus regis*, probably an occasional magistrate, answering to the modern justice of assize, or perhaps an officer whose duty it was to prosecute for the Crown; and *aldermannus comitatus*, a magistrate with a middle rank between what was afterwards called the *earl* and the *sheriff*, who sat at the trial of causes with the bishop and declared the common law, while the bishop proceeded according to ecclesiastical law. Besides these, we meet with the titles of *aldermannus civitatis*, *burgi*, *castelli*, *hundredi sive wapentachii*, etc. In England, before the passing of the Municipal Corporations act, their functions varied according to the charters of the different boroughs. By the Municipal Corporations act 1835, and other acts, consolidated by the Municipal Corporations act 1882, the aldermen are elected by the councillors for six years, one-half going out every three years. The number of councillors in each borough varies according to its magnitude. One-fourth of the municipal council consists of aldermen and three-fourths of councillors. In the counties, the number of aldermen is one-third of the number of councillors, except in London, where it is one-sixth. The corporation of the City of London was not included in the Borough Reform act, and the antiquated system remains there in full force. The court of aldermen consists of 26, 25 of whom are elected for life by the freemen of the respective wards, who return two persons, one of whom the court of aldermen elect to supply the vacancy. The city is divided into 26 wards; 24 of these send up one alderman each, the other two combine to choose a 25th. The 26th alderman serves for the independent borough of Southwark (*q.v.*) and is appointed by the other aldermen, who generally select the senior from among themselves when a vacancy occurs. The lord mayor is elected from such of the aldermen as have served the office of sheriff; of these the common hall, which consists of the freemen of the different wards, select two, and the aldermen elect one of these to the mayoralty. The court of aldermen has the power of appointment to certain offices, exercises judicial functions in regard to licensing and in disputes connected with the ward election, has some power of disposal over the city cash and possesses magisterial control over the city, each alderman being a judge and magistrate for the whole city, and by virtue of his office exercising the functions of a justice of the peace. The aldermen are members of the court of common council, the corporation's legislative body, consisting of 232 members, the remainder being elected annually by the freemen.

In the United States aldermen form as a rule a legislative rather than a judicial body, although in some cities they hold courts and possess very considerable magisterial powers.

ALDERNEY, the northernmost of the larger Channel Islands, $3\frac{1}{2}$ m. N.E.-S.W., average width 1 mile. Area, 1,962 ac. Pop. (1921) 1,598. It lies $49^{\circ}43'$ N. and $2^{\circ}12'$ W. On the north coast, Braye harbour, with a fine breakwater, communicates twice or three times weekly with St. Peter Port, Guernsey, and weekly with Cherbourg, France. Rocks fringe all the coasts. A dangerous channel nearly 9 m. wide, known as the Race, separates it from Cap de la Hague. Here the remnant of the French fleet under Tourville escaped after the defeat of La Hogue in 1692. To the west, the Swinge (Singe), a narrower and equally difficult tidal race, separates Alderney from the uninhabited islands of Burhou, Ortach and others; still further west are the Casquets (lighthouse) which have a long record of shipwrecks. Alderney is a tableland 300 ft. high in the west, but dropping towards the north-east. On the south the cliffs are very steep; elsewhere rocky headlands alternate with open sandy bays, of which the most important are Braye and Longy. At the latter there are evidences of settlement in prehistoric and in Roman times. Cambrian grits occur along the north-east coast, and south of Longy give rise to the Hanging Rocks; diorite and granite occupy the central, and granite-porphry the south-west portion of the island. There are a few streams, but water is obtained mainly from wells. Trees are scarce. The town of St. Anne stands almost in the centre of the island with its arable land around it. This is largely unenclosed and still shows the old arrangement in strips. It was long under a system of continuous corn-growing, now superseded. It is encircled by the grazing lands which were communal until 1830. The modern church (1850), in Early English style, is the work of Sir Gilbert Scott, and a memorial to the Le Mesurier family, in which the hereditary governorship of the island was vested until the abolition of the office in 1825. There is a chain of derelict fortifications round the north coast, but Fort Tourgis on the west and Fort Essex on the east are still used as barracks. The soil of Alderney is fertile, grain and roots are grown and early potatoes are exported. Alderney cattle are largely reared and are usually kept tethered, but the island does not possess a stock book separate from Guernsey. Alderney is included in the bailiwick of Guernsey. Its court, consisting of a judge, six jurats, attorney general, prévôt, greffier and sergent, is subordinate to that of Guernsey. For its relations to the constitution of the bailiwick and for its history see CHANNEL ISLANDS.

ALDERSHOT, municipal borough, Hampshire, England, 34 m. S.W. by W. of London, on the Southern railway. Aldershot was a mere village till 1855 when a camp was established. Pop. (1891) 25,595; (1931) 34,281. Its germ is to be found in the temporary training camp on Chobham Ridges, formed in 1853 by Lord Hardinge, the military commander-in-chief, who also advised the choice of Aldershot as a permanent camp. The Government acted on his suggestion after the experience of the Crimea. Under the Military Works Act of 1897 and 1899 large sums were provided for completing the work. The town grew in size and importance as the camp became the centre of military training for the country. During 1904-14, besides troops in barracks, large numbers of militia and volunteer units gathered at Aldershot, during training periods, using the famous range at Bisley near by. The enormous and rapid development of all branches of the army and the rise of many new ones, during 1914-18 led to the formation of many new and some larger camps elsewhere. It became a great demobilization camp in 1918-19. Since 1919, its importance has declined. Aldershot is in the parliamentary division of Hampshire of the same name. The borough is governed by a mayor and corporation of 24 members. Area of municipal borough 4,176 acres.

ALDHELM (c. 640-709), bishop of Sherborne, English scholar, was born before the middle of the 7th century. He is said to have been the son of Kenten, who was of the royal house of Wessex, but who was certainly not, as Aldhelm's early biographer Faritus asserts, brother of King Ine. He received his first education in the school of an Irish scholar and monk, Mail-

dulf, Maeldubh, or Meldun (d. c. 675), who had settled in the British stronghold of Bladon or Bladow on the site of Malmesbury. Aldhelm was a pupil of Hadrian, abbot of St. Augustine's, Canterbury, whom he addresses as the "venerable preceptor of my rude childhood." He must, nevertheless, have been 30 years of age when he began to study with Hadrian. His studies included Roman law, astronomy, astrology, the art of reckoning, and the difficulties of the calendar. He learned, according to the doubtful statements of the early lives, both Greek and Hebrew. Ill-health compelled him to leave Canterbury, and he returned to Malmesbury. When Maildulf died, Aldhelm was appointed in 675 to succeed him, and became the first abbot. He introduced the Benedictine rule, and secured the right of the election of the abbot to the monks themselves. The community at Malmesbury increased, and Aldhelm was able to found two other centres of learning at Frome and at Bradford-on-Avon. The little church of St. Lawrence at Bradford may safely be regarded as his. At Malmesbury he built a new church to replace Maildulf's modest building, and obtained considerable grants of land for the monastery. His fame as a scholar rapidly spread into other countries. Aldhelm was the first Englishman, so far as we know, to write in Latin verse, and his letter to Acircius (Aldfrith or Eadfrith, king of Northumbria) is a treatise on Latin prosody for the use of his countrymen. In this work he included his most famous productions, 101 riddles in Latin hexameters. Each of them is a complete picture, and one of them runs to 83 lines. That his merits as a scholar were early recognized in his own country is shown by the encomium of Bede (*Eccl. Hist.* v. 18), who speaks of him as a wonder of erudition. His fame reached Italy, and at the request of Pope Sergius I. (687-701) he paid a visit to Rome, of which, however, there is no notice in his extant writings. He was deputed by a synod of the church in Wessex to remonstrate with the Britons of Domnonia (Devon and Cornwall) on their differences from the Roman practice in the shape of the tonsure and the date of Easter. This he did in a long and rather acrimonious letter to their king Geraint (Geruntius), and their ultimate agreement with Rome is referred by William of Malmesbury to his efforts. In 705 Aldhelm became bishop of the new see of Sherborne. He wished to resign the abbey of Malmesbury which he had governed for 30 years, but yielding to the remonstrances of the monks he continued to direct it until his death. The cathedral church which he built at Sherborne, though replaced later by a Norman church, is described by William of Malmesbury. He was on his rounds in his diocese when he died in the church of Doulting on May 25, 709. He was buried in the church of St. Michael, Malmesbury. Aldhelm wrote poetry in Anglo-Saxon also, and set his own compositions to music, but none of his songs, which were still popular in the time of Alfred, have come down to us.

Aldhelm's works were collected in J. A. Giles's *Patres eccl. Angl.* (1844), and reprinted by J. P. Migne in his *Patrologiae Cursus*, vol. lxxxix. (1850). The letter to Geraint, king of Domnonia, was supposed to have been destroyed by the Britons (W. of Malmesbury, *Gesta Pontificum*, p. 361), but was discovered with others of Aldhelm's in the correspondence of St. Boniface, archbishop of Mainz. A long letter to Eadfrid, a scholar just returned from Ireland (first printed in *Usserii Veterum Epist. Hiber.-Sylloge*, 1632), is of interest as casting light on the relations between English and Irish scholars. Next to the riddles, Aldhelm's best-known work is *De Laude Virginitatis sive de Virginitate Sanctorum*, a Latin treatise addressed about 705 to the nuns of Barking, in which he commemorates a great number of saints. This was afterwards turned by Aldhelm into Latin verse (printed by Delrio, Mainz, 1601). The chief source of his *Epistola ad Acircium sive liber de septenario, et de metris, aenigmatibus ac pedum regulis* (ed. A. Mai, *Class. Auct.* vol. v.) is Priscian. For the riddles included in it, his model was the collection known as *Symposii aenigmata*. The acrostic introduction gives the sentence, "Aldhelmus cecinit millenis versibus odas," whether read from the initial or final letters of the lines. His Latin poems include one on the dedication of a basilica built by Bugge (or Eadburga), a royal lady of the house of Wessex.

BIBLIOGRAPHY.—Faritius (d. 1117), an Italian monk of Malmesbury, afterwards abbot of Abingdon, wrote a *Vita S. Aldhelmi* (ms. Cotton, Faustina, B. 4), printed by Giles and Migne, also in *Original Lives of Anglo-Saxons* (Caxton Soc., 1854); but the best authority is William of Malmesbury, who in the fifth book, devoted to St. Aldhelm, of the *Gesta Pontificum* proposes to fill up the outline of Faritius, using the church records, the traditions of Aldhelm's miracles preserved by the monks of Malmesbury, and the lost "Handbook" or commonplace book of King Alfred. (See *De Gestis Pontificum*, ed.

N. E. S. A. Hamilton, 1870, for the Rolls Series, pp. 330-443.) The life by John Capgrave in his *Legenda Nova* (1516) is chiefly an abridgement of Malmesbury's narrative. Consult also L. Bönhoff, *Aldhelm von Malmesbury* (1894); G. F. Browne, bishop of Bristol, *St. Aldhelm: His Life and Times* (1903); and W. B. Wildman, *Life of S. Ealdhelm, first Bishop of Sherborne* (1905), containing many interesting local details. For some poems attributed to Aldhelm, and printed in Dümmler's edition of the letters of St. Boniface and Lul in *Monumenta Germaniae Historica* (epist. tom. iii.), see H. Bradley in *Eng. Hist. Review*, xv. p. 291 (1900), where they are attributed to Aldhelm's disciple Aethelwald. The very varied sources and the chronology of Aldhelm's work are discussed in "Zu Aldhelm und Baeda," by Max Manitius, in *Sitzungsberichte der kaiserlichen Akad. der Wissenschaften* (1886).

An excellent account of his ecclesiastical importance is given by W. Bright in *Chapters on Early English Church History* (1878).

For his position as a writer of Latin verse consult A. Ebert, *Allgemeine Geschichte d. Literatur des Mittelalters im Abendlande*, vol. i. new edition (1889); M. Manitius, *Geschichte der christlichlateinischen Poesie*, etc. (Stuttgart, 1891), pp. 487-496; also H. Hahn, *Bonifat und Lul ihre angelsächsischen Korrespondenten*, chap. i. (Leipzig, 1883). The two last-named works contain many further bibliographical references.

ALDINE PRESS, the printing office started by Aldus Manutius at the end of the 15th century in Venice, from which were issued the celebrated Aldine editions of the classics of that time. (See MANUTIUS.) The Aldine Press is famous in the history of typography (*q.v.*), among other things, for the introduction of italics.

ALDRED or **EALDRED** (d. 1069), English ecclesiastic, became abbot of Tavistock about 1027, in 1044 was made bishop of Worcester, and in 1060 archbishop of York. It is stated by Florence of Worcester that Aldred crowned King Harold II. in 1066, although the Norman authorities mention Stigand as the officiating prelate. After the battle of Hastings, Aldred joined the party who sought to bestow the throne upon Edgar the Aetheling, but when these efforts appeared hopeless he was among those who submitted to William the Conqueror at Berkhamstead. Selected to crown the new King, he performed the ceremony on Christmas Day 1066, and in 1068 performed the same office at the coronation of Matilda, the Conqueror's wife. He died at York on Sept. 11, 1069, and was buried in his own cathedral.

Thorpe (London, 1848-49); William of Malmesbury, *De Gestis Pontificum Anglorum*, edited by N.E.S.A. Hamilton (London, 1870); W. H. Dixon, *Fasti Eboracenses*, vol. i., edited by J. Raine (London, 1863); T. Stubbs, *Chronica Pontificum Ecclesiae Eboracensis*, edited by J. Raine (London, 1879-94); E. A. Freeman, *History of the Norman Conquest*, vol. ii., iii., iv. (Oxford, 1867-79).

ALDRICH, HENRY (1647-1710), dean of Christ Church, Oxford, and in 1692 vice-chancellor of the University, was born at Westminster in 1647, and died at Oxford Dec. 14, 1710. He was a man of versatile talent, who wrote a *Compendium Artis Logicae* used as a text-book in Oxford far into the 19th century, composed many excellent anthems and church services and adapted much church music of Palestrina and Carissimi to English words with skill and judgment. He designed the church and campanile of All Saints and the Peckwater quadrangle of Christ Church.

Dean Aldrich bore a great reputation for conviviality, and wrote a humorous Latin version of the popular ballad:

A soldier and a sailor,
A tinker and a tailor, etc.

Another specimen of his wit is furnished by the following epigram of the five reasons for drinking:

*Si bene quid memini, causae sunt quinque bibendi;
Hospitis adventus, praesens sitis atque futura,
Aut vini bonitas, aut quaelibet altera causa.*

The translation runs:

If on my theme I rightly think,
There are five reasons why men drink:—
Good wine; a friend; because I'm dry;
Or lest I should be by and by;
Or—any other reason why.

ALDRICH, NELSON WILMARTH (1841-1915), American politician, was born at Foster, R.I., on Nov. 6, 1841. His

first political service was as a member (1869-75) and president (1871-72) of the Providence common council. He was a member of the lower house of the Rhode Island legislature in 1875-76, and speaker in the latter year. By this time he had become very influential in Republican State politics, and in 1878 and again in 1880 was elected to Congress. In 1881 he resigned to take a seat in the Senate, where he served continuously for 30 years. By reason of his mastery of parliamentary detail and his skill in bringing about combinations of opposing groups, he became one of the most powerful leaders of the Republicans in the Senate. He was an able champion of protection and an authority on finance, and his knowledge of these subjects was embodied in various tariff and currency enactments. He sponsored the Aldrich-Vreeman currency law of 1908. As chairman of the national monetary commission, brought into existence by that Act, he directed extensive investigations of the banking systems of the world. He published a scheme, based on the information thus secured, for the reform of the American banking system known as the Aldrich plan. He also was largely responsible for the Payne-Aldrich Tariff Act of 1909, which, by reason of its high rates, aroused much opposition, especially in the agrarian districts. Because of his extensive personal financial interests and his intimate connection with powerful financial groups, he came to be looked upon as the special representative of the moneyed interests and of the highly protected industries. He died in New York city on April 16, 1915.

ALDRICH, RICHARD (1863-), music critic, was born at Providence, R.I., July 31, 1863. He studied at Harvard under J. K. Paine and in Germany. Associate critic of the *New York Tribune* 1891-1902, he then became music critic to the *New York Times*, holding the position to 1924, except for the period Feb. 1918-May 1919, when he was captain in the Military Intelligence Division, U.S.A. He prepared a volume on Schumann, edited a series of musical biographies, collaborated with H. E. Krehbiel in *History of the Philharmonic Society*, translated Lilli Lehman's *How to Sing*, and wrote *A Guide to Parsifal* and *A Guide to the Nibelungen Ring*.

ALDRICH, THOMAS BAILEY (1836-1907), American author, was born in Portsmouth, N.H., Nov. 11, 1836. The deepest impressions of his boyhood were made by the exotic city of New Orleans and the historic town of Portsmouth, which he portrays in his autobiographical *Story of a Bad Boy* (1870). He had been taken to Portsmouth to prepare for Harvard, a plan which his father's death made impracticable. After spending several years as clerk in his uncle's office in New York, the publi-

FROM STODDARD, "POETS' HOMES"

THE HOUSE AT PONKAPOG, MASSACHUSETTS. ONE-TIME HOME OF THOMAS BAILEY ALDRICH, CELEBRATED FOR THE "STORY OF A BAD BOY"

cation of his first book of verse *The Bells* (1855) and the success of his "Ballad of Babie Belle" caused him to resign to become junior literary critic on the *Evening Mirror*. He soon became sub-editor of Willis's other magazine, the *Home Journal*, and for the remainder of his life, with the exception of the time spent as war correspondent for the *Tribune*, he devoted himself to creative and editorial work. He was for short periods adviser to different publishing houses, but his chief work was with the magazines—the *Saturday Press* (1859-60), the *Illustrated News*

(1863), *Every Saturday* (1865-74), and the *Atlantic Monthly* (1881-90). Although he made intimate friends of the young poets, artists and wits of New York, the cultural atmosphere of New England in which, according to him, he became "Boston plated," and the frequent European tours of his later life undoubtedly were the most influential factors in ripening his art. Few poets have so ruthlessly discarded their earlier poems in their later editions, Aldrich even going so far as to buy and destroy every copy of *Pampinea* (1861) that he could find. His verse is better studied, then, in his later volumes, chiefly *Cloth of Gold* (1874), *Flower and Thorn* (1877), *Friar Jerome's Beautiful Book* (1881), *Mercedes and Later Lyrics* (1884), *Windham Towers* (1890), and the collected editions of 1865, 1882, 1897 and 1906. These showed him to be a poet of lyrical skill, dainty touch and felicitous conceit. In describing some single picture, mood, conceit or episode, no American poet has shown more skill. He repeatedly essayed the long narrative or dramatic poem but with less success. Beginning with the collection of stories entitled *Marjorie Daw and Other People* (1873), Aldrich applied to his later prose work that minute care in composition which had previously characterized his verse. His use of the surprise ending was perhaps the most effective feature of his short stories. *Prudence Palfrey* (1874), *The Queen of Sheba* (1877), and *The Stillwater Tragedy* (1880), novels, lack depth of characterization and vitality; but his *Story of a Bad Boy* (1870) has become an American classic. *A Rivermouth Romance* (1877) and *An Old Town by the Sea* (1893) commemorate with affectionate touch the author's birthplace; *From Ponkapog to Pesth* (1883) is made up of pleasant travel sketches; and *Ponkapog Papers* (1903), of pungent jottings and whimsical essays. Aldrich's later life was saddened by the death of his son, Charles, but his serenity, urbanity and charm never wholly deserted him. He died in Boston, March 19 1907.

Aldrich's *Writings* were collected in 1897 and in 1907 (Ponkapog ed.). Ferris Greenslet is the author of a sympathetic *Life* (1908), and Mrs. Aldrich wrote a pleasant volume of reminiscence, *Crowding Memories* (1920).

ALDRINGER (ALTRINGER, ALDRINGEN), JOHANN, COUNT VON (1588-1634), Austrian soldier, was born at Diedenhofen (Thionville) in Lorraine. He had behind him 25 years' service in the Spanish Army when he returned to Germany in 1631. He served after Breitenfeld as Tilly's artillery commander, and he was present at the battle of the Lech, where he was wounded. When Tilly died of his wounds, Aldringer, who was now a count of the empire, succeeded to the command. Made field-marshal after the assault of the Alte Veste, near Nuremberg, at which he had been second in command under Wallenstein, duke of Friedland (with whom he was a great favourite), he was next placed at the head of the corps formed by Maximilian I. of Bavaria to support Wallenstein.

Finally Aldringer was won over by the court party which sought to displace the too successful duke of Friedland. After Wallenstein's death Aldringer commanded against the Swedes on the Danube, and at the defence of Landshut he fell (July 22 1634). His great possessions descended to his sister, and thence to the family of Clary and Aldringen.

See Brohm, *Johann von Aldringen* (Halle, 1882), and Hermann Hallwich, *Johann von Aldringen* (Leipzig, 1885); also *Allgemeine Deutsche Biographie*, s.v. Gallas, correcting earlier biography of Aldringer in the same work.

ALDROVANDI, ULISSI (1522-1605), Italian naturalist, was born of noble parentage at Bologna, where he was professor of natural history from 1560 onwards. At his instance the senate of Bologna established in 1568 a botanical garden, of which he was appointed the first director. About the same time he became inspector of drugs, and in that capacity published in 1574 a work entitled *Antidotarii Bononiensis Epitome*, which formed the model for many subsequent pharmacopoeias. The results of his various researches were embodied in a great *Natural History*. The first three volumes, comprising his ornithology, were published in 1599, and a fourth, treating of insects, appeared in 1602. The value of the work is increased by the number and beauty of its illustrations. After his death a number of other volumes

were compiled from his manuscript materials under the editorship of several of his pupils.

ALE, an old word for a fermented liquor obtained chiefly from malt. The derivation is from Ang.-Sax. *ēalu*, a sort of beer. In England "ale" is nowadays almost synonymous with "beer." Before the introduction of hops into England from Flanders in the 16th century, ale was the name exclusively applied to malt liquor, the term beer being gradually introduced to describe liquor brewed with an infusion of hops. This distinction does not now apply, except in so far as the term "ale" is not applied to black beers (stout and porter) nor to lager beer. In the United States, however, it was customary to confine the designation "beer" to the article obtained by the bottom fermentation process. In former times the Welsh and Scots had two distinct kinds of ale, called common and spiced ales, the relative values of which were appraised by law in the following terms: "If a farmer have no mead, he shall pay two casks of spiced ale, or four casks of common ale, for one cask of mead." There are numerous varieties of English ales, such as mild ale, which is a full, sweetish beer, of a dark colour and with relatively little hop; pale ale, which is relatively dry, of light colour and of a more pronounced hop flavour than the mild ale; and bitter and stock ales, the latter term being generally reserved for superior beers, such as are used for bottling. The terms pale, bitter, stock, light, etc., are to be regarded as trade distinctions and not as exact definitions of quality or type.

Parish Ales.—In old England an "ale" was synonymous with a parish festival or merry-making at which ale was the chief drink. The word was generally used in composition. Thus there were leet-ales (that held on leet or manorial court day); lamb-ales (that held at lamb-shearing); Whitsun-ales, clerk-ales, church-ales and so on. The word *bridal* is really bride-ale, the wedding feast. Bid-ales, once very common throughout England, were "benefit" feasts to which a general invitation was given, and all the neighbours attending were expected to make some contribution to help the object of the "benefit." (See *Bidding-Weddings* under BRIDE.) These parish festivals were of much ecclesiastical and social importance in mediaeval England. The chief purpose of church-ales and clerk-ales, at least, was to facilitate the collection of parish-dues, or to make an actual profit for the church from the sale of the liquor by the churchwardens. These profits kept the parish church in repair, or were distributed as alms to the poor. At Sygate, Norfolk, on the gallery of the church is inscribed:

God speed the plough
And give us good ale enow . . .
Be merry and glade,
With good ale was this work made.

On the beam of a screen in the church of Thorpe-le-Soken, Essex, is the following inscription in raised Gothic letters, on a scroll held by two angels: "This cost is the bachelers made by ales thesen be ther med." The date is about 1480. The feast was usually held in a barn near the church or in the churchyard. In Tudor times church-ales were held on Sundays. Gradually the parish-ales were limited to the Whitsun season, and these still have local survivals. The colleges of the universities used formerly to brew their own ales and hold festivals known as college-ales. Some of these ales are still brewed and famous, like "chancellor" at Queen's college, and "archdeacon" at Merton college, Oxford, and "audit ale" at Trinity, Cambridge. (See BEER.)

See Brand's *Popular Antiquities of Great Britain* (Wm. Carew Hazlitt's edition, 1905).

ALEANDRO, GIROLAMO (HIERONYMUS ALEANDER) (1480-1542), Italian cardinal, one of the greatest scholars of his time, was born at Motta, near Venice on Feb. 13, 1480, and died at Rome on Feb. 1, 1542. He was for some time rector of the University of Paris. In 1520 he was sent to Germany as papal nuncio at the coronation of Charles V., and was also present at the Diet of Worms, where he headed the opposition to Luther. The edict against the reformer, which was finally adopted by the emperor and the Diet, was drawn up and proposed by Aleandro. After the close of the Diet the papal nuncio went to the Netherlands, where he kindled the flames of persecution, two monks of Antwerp, the first martyrs of the Reformation,

being burnt in Brussels at his instigation. In 1523 Clement VII. sent him as nuncio to the court of Francis I. He was taken prisoner at the battle of Pavia (1525), and was released only on payment of a heavy ransom. He was subsequently employed on various papal missions, especially to Germany, but was unable to check the progress of the new doctrines. He was created cardinal in 1536 by Paul III.

Aleandro compiled a *Lexicon Graeco-Latinum* (1512), and wrote Latin verse of considerable merit inserted in M. Tuscanus's *Carmina Illustrium Poetarum Italiorum*. The Vatican library contains a volume of ms. letters and other documents written by him in connection with his various missions against Luther. They were utilized by Pallavicino in his *Istoria del Concilio Tridentino* (i. 23-28), who gives a very partial account of the Worms conference.

Aleandro, who is sometimes called "the elder," must be distinguished from his grand-nephew, also called Girolamo Aleandro (1574-1629). The younger Aleandro was a very distinguished scholar, and wrote *Psalmi poenitentiales versibus elegiacis expressi* (1593); *Gaii, veteris juris consulti Institutionum fragmenta, cum commentario* (1600); *Explicatio veteris tabulae marmoreae solis effigie symbolesque exculptae* (1616).

ALEARDI, ALEARDO, COUNT (1812-1878), Italian poet, was born at Verona on Nov. 4, 1812, and thus soon after his birth became an Austrian subject. Inspired from his cradle with a hatred of the foreigner, he found himself unable to publish his patriotic verses. But the revolutionary year 1848 made an opening for his *Lettere a Maria*. He took an active part in the popular uprising, and was for some time imprisoned. In 1856 he produced the finest of his pieces, an ode to the maritime cities of Italy, and in 1858 a poem on his own misfortunes. After the expulsion of the Austrians from Lombardy he returned to Verona, published his poems in a collected edition (1862), became professor at the Academy of Fine Art, member of the Italian parliament and eventually senator. Aleardi's warmth of patriotic feeling hardly finds adequate expression in his poetry; it is his merit to excel in description, but his fault to substitute description for action.

ALE-CONNER, an officer appointed yearly at the court-leet of ancient English manors for the assize of ale and ale-measures. The *gustatores cervisiae*—called in different localities by the different names "ale-tasters," "ale-founders" and "ale-conners"—were sworn to examine beer and ale, to take care that they were good and wholesome and were sold at proper prices. With modern methods of assessing the excise on beer and ale the custom of appointing ale-tasters has in most places fallen into disuse. (See ADULTERATION.)

ALECSANDRI or **ALEXANDRI, VASILE** (1821-1890), Rumanian lyric poet, was born at Bacau in Moldavia and educated first in Jassy and afterwards (1834-39) in Paris. In 1839 he began to collect Rumanian popular songs. He first published his collection in 1844. His *Doine și Lacrimioare*, lyrical poems, appeared at Paris in 1852, and in 1852-53 he produced at Jassy a fuller collection of popular ballads and songs. In 1867 he published some fugitive pieces, written in a lighter vein and entitled *Pastele*; these were followed in 1871 by the *Legende* of similar character. More serious are his dramatic writings which began with *Despot Voda* and culminated in *Ovid*. In later life Alecsandri took an active part in politics; he became minister for foreign affairs (1859-60), and in 1885 was appointed Rumanian minister in Paris. His best title to fame consists in the fact that he gave the first impetus to the collection of Rumanian popular songs and first drew attention to their inimitable charm.

See L. Sainsanu, *Autori Români moderni* (1891), pp. 90 and 318. A complete edition of Alecsandri's writings was published at Bucharest in 1875 seq. (9 vols.).

ALEKHINE, ALEXANDER (1892-), champion chess-player, was born in Moscow on Nov. 1, 1892. He displayed precocious ability as a chess-player, and in 1910 he did well at the Hamburg tournament at the age of seventeen. When the World War broke out in 1914 he was playing at the Mannheim tournament and escaped from internment to serve in the Red Cross division of the Russian army. After the Revolution he became a

naturalized Frenchman, and studied law at the University of Paris. The winner of 20 international tournaments, he won the world championship for blindfold chess (New York, 1924). In 1927 he won the chess championship of the world from Capablanca, who had held it since 1921.

For his methods see his book, *My Best Hundred Games* (Eng. trans., 1927).

ALEMÁN, MATEO (1547-1609?), Spanish novelist and man of letters, was born at Seville. He graduated at Seville university in 1564, studied later at Salamanca and Alcalá, and from 1571 to 1588 held a post in the treasury; in 1594 he was arrested on suspicion of malversation, but was speedily released. In 1599 he published the first part of *Guzmán de Alfarache*, a celebrated picaresque novel which passed through not less than 16 editions in five years, and was translated into French (1600), English (1623) and Latin (1623); a spurious sequel was issued in 1602, but the authentic continuation did not appear till 1604. In 1608 Alemán emigrated to America, and is said to have carried on business as a printer in Mexico City; his *Ortografía castellana* (1609), published there, contains ingenious and practical proposals for the reform of Spanish spelling. Nothing is recorded of Alemán after 1609, but it is sometimes asserted that he was still living in 1617.

BIBLIOGRAPHY.—See J. Hazañas y la Rua, *Discursos leídos en la Real Academia Sevillana de Buenas letras el 25 de marzo de 1892* (Sevilla, 1892); J. Gestoso y Perez, *Nuevos datos para ilustrar las biografías del Maestro Juan de Malara y de Mateo Alemán* (Sevilla, 1896).

ALEMBERT, JEAN LE ROND D' (1717-1783), French mathematician and philosopher, was born at Paris in Nov. 1717. He was a founding but it afterwards became known that he was the illegitimate son of the Chevalier Destouches and Madame de Tencin. The infant was entrusted to the wife of a glazier named Rousseau who lived close by the Church of St. Jean le Rond, where the child was found. Destouches, without disclosing his identity, provided for the boy, who was educated at the Mazarin College under the Jansenists.

On leaving college he returned to the house of his foster-mother, where he continued to live for 30 years. Having studied law, he was admitted as an advocate in 1738, but did not enter upon practice. He next devoted himself to medicine; but his natural inclination proved too strong for him, and within a year he resolved to give his whole time to mathematics. In 1741 he received his first public distinction in being admitted a member of the Academy of Sciences, to which he had previously presented several papers, including a *Mémoire sur le calcul intégral* (1739). In his *Mémoire sur la réfraction des corps solides* (1741) he was the first to give a theoretical explanation of the phenomenon which is witnessed when a body passes from one fluid to another more dense in a direction not perpendicular to the surface which separates the two fluids. In 1743 he published his *Traité de dynamique*, a work famous as developing the mechanical principle, known as "d'Alembert's principle," first enunciated in 1742 (see MECHANICS). In 1744 d'Alembert applied this principle to the theory of the equilibrium and the motion of fluids, *Traité de l'équilibre et du mouvement des fluides*, and all the problems before solved by geometers became in some measure its corollaries. This discovery was followed by that of the calculus of partial differences, the first trials of which were published in his *Réflexions sur la cause générale des vents* (1747). This work was dedicated to Frederick the Great, who made several unsuccessful attempts to induce him to settle in Berlin. In 1763 he visited Berlin, and on that occasion finally refused the office of president of the Academy of Berlin, which had been already offered to him more than once. In 1747 he applied his new calculus to the problem of vibrating chords, the solution of which, as well as the theory of the oscillation of the air and the propagation of sound, had been given but incompletely by the geometers who preceded him. In 1749 he furnished a method of applying his principles to the motion of any body of a given figure; and in 1754 he solved the problem of the precession of the equinoxes, determined its quantity and explained the phenomenon of the nutation of the earth's axis. In 1752 he published an *Essai d'une nouvelle théorie sur la résistance des fluides*, which contains a large number of original ideas and new observations. In

1746 and 1748 he published in the *Memoirs* of the Academy of Berlin "Recherches sur le calcul intégral," a branch of mathematical science which is greatly indebted to him. In his *Recherches sur différents points importants du système du monde* (1754-56) he perfected the solution of the problem of the perturbations of the planets, which he had presented to the academy some years before.

D'Alembert's association with Diderot in the preparation of the *Dictionnaire Encyclopédique* led him to a wider range of work. He contributed the *Discours préliminaire* on the rise, progress, and affinities of the various sciences, which he read to the French Academy on the day of his admission as a member, Dec. 18, 1754. He also wrote several literary articles for the first two volumes of the encyclopaedia, and to the remaining volumes he contributed mathematical articles chiefly. Of d'Alembert's works on other than mathematical subjects the most important is the *Éléments de Philosophie* (1759) in which he discussed the principles and methods of the different sciences. D'Alembert was much interested in music both as a science and as an art, and wrote *Éléments de musique théorique et pratique* (1779), which was based upon the system of J. P. Rameau with important modifications and differences.

D'Alembert continued to the end to lead the quiet and frugal life dictated by his limited means as well as his simple tastes. His later years were saddened by the death of Mademoiselle de Lespinasse, whose acquaintance he made at the house of Madame du Deffand. She nursed him assiduously during an illness he had in 1765, and from that period till her death in 1776 they lived in the same house. On her part there seems to have been from first to last nothing more than warm friendship, but his feelings towards her were of a stronger kind and her death deeply affected him. He never recovered his elasticity of spirits, though he continued to occupy himself with his favourite pursuits, and to frequent the society of his brother philosophers. After the death of Voltaire (1778), whose friend and correspondent he had been for more than 30 years, he was regarded as the leader of the philosophical party in the Academy. He died at Paris on Oct. 29, 1783.

BIBLIOGRAPHY.—The scientific works of d'Alembert have never been published in a collected form. The most important of them have been mentioned above, with the exception of the *Opusculs mathématiques* (1761-80). His literary and philosophical works were collected and edited by Bastien (1805). A better edition by Bossange was published at Paris in 1821. The best account of the life and writings of d'Alembert is contained in Condorcet's *Éloge*, presented to the Academy and published in 1784.

ALEMBIC, an apparatus for distillation (*q.v.*) used chiefly by the alchemists, and now superseded by more convenient forms of still, both in the laboratory and in the factory. It consisted essentially of three parts: a vessel containing the material to be distilled and called, from its gourd-like shape, the cucurbit, or matrass; a vessel to receive and condense the vapour, called the head or capital; and a receiver for the distillate, connected by a pipe with the capital. The entire apparatus was sometimes constructed of glass, but more usually the cucurbit was of copper or earthenware, and the capital alone of glass.

ALENÇON, COUNTS AND DUKES OF. The first line of the counts of Alençon was founded by Yves, lord of Bellesme, who in the middle of the 10th century possessed and fortified the town of Alençon. Mabile, countess of Alençon and heiress of this family (d. 1082) married Roger of Montgomery, and from them descended a second house of Alençon which became extinct in the person of Robert IV.; the county of Alençon was then joined to the royal domain. It was successively granted as an appanage to Peter, son of St. Louis (1268), and to Charles, count of Valois, brother of Philip the Fair (1293). The third house of Alençon sprang from Charles, second son of the count of Valois, who was killed at the battle of Crécy in 1346.

The countship of Alençon was raised to a peerage in 1367 and into a dukedom in 1414. John, 1st duke of Alençon, was killed at Agincourt on Oct. 25, 1415, after having with his own hand slain the duke of York. His son, John, was dispossessed of his duchy by the King of England, but reconquered it in 1449. In 1524 the dukedom of Alençon reverted to the crown, in consequence of the

death of the Duke Charles IV. without issue. It was given as a jointure to Catherine de' Medici in 1559, and as an appanage to her son Francis in 1566. It was pawned by Henry IV. to the duke of Württemberg, and subsequently it passed to Gaston, duke of Orleans, by grant of Louis XIII.; to Elizabeth of Orleans, duchess of Guise; to Charles, duke of Berry, grandson of Louis XIV. (1710); and to Monsieur (Louis XVIII.), brother of Louis XVI.

The title of duc d'Alençon was given to Ferdinand of Orleans, son of the duc de Nemours, and grandson of Louis-Philippe.

ALENÇON, north-west France, capital of department of Orne, 36m. N. of Le Mans on a branch of the Western railway. Pop. (1926) 13,447. The regularly built town lies in a wide and fertile plain at the confluence of the Sarthe and Briante. The ancient castle, taken by William of Normandy in 1048, is in ruins save for one 14th and two 15th century towers. Notre Dame, the chief church (15th century), has an ornamented Gothic porch, and 16th century stained windows. The manufacture of *point d'Alençon* (a species of lace copied from Venice and introduced by Colbert) is still pursued. Weaving and bleaching of cloth, printing, the manufacture of vehicles, of boots and shoes and of bricks are carried on; there is trade in the horses of the district. Alençon is the seat of a prefect and a court of assizes. It has tribunals of first instance and of commerce, a board of trade arbitrators, a chamber of arts and manufactures, and corn and cloth markets.

ALenio, GIULIO (ah-lā'nē-ō) (1582-1649), Italian Jesuit missionary, was born at Brescia. He landed at Macao in 1610, and penetrated into China three years later. During his 30 years' residence in China he adopted the dress and manners of the country, was the first Christian missionary in Kiang-si, and built several churches in Fukien. He wrote in Chinese a *Life of Christ* (Peking, 1635-37, 8 vol.; often reprinted, e.g., in 1887 in 3 vol., and used even by Protestant missionaries) and a cosmography (*I che fang wai ki Hang-chow*, 1623, 6 vol.), which was translated into Manchu under the title *The True Origin of 10,000 Things*, a copy of which was sent from Peking to Paris in 1789. Alenio died at Fuchow in 1649.

For bibliography see de Backer and Sommervögel, *Bibl. de la Cie. de Jésus*, i. 158-160.

ALENTEJO, ancient province of central and southern Portugal; bounded on the north by Beira, east by Spanish Estremadura and Andalusia, south by Algarve and west by the Atlantic ocean and Portuguese Estremadura. Pop. (1900) 416,105; area 9,219sq.m. The principal rivers are the Tagus, which divides Alentejo from Beira; the Guadiana, which, crossing the Spanish frontier, flows southwards through the province; and the Sado, which rises in the Serra de Monchique, and flows to the north. There are several extensive plains, notably that lying south-west of the Serra de Portalegre; that of Beja, between the Sado and Guadiana; and of Ourique, farther south between the same rivers. Some portions of these plains are fruitful, others marshy, while large tracts are desolate.

The climate in the lowland is hot and unhealthy in summer because of stagnant marshes. Towards the Spanish frontier the soil is fertile, and in the south are extensive forests of oak, pine, chestnut, cork and ilex, especially on the sides of the Mezquita and Caldeirão ranges. In the more fertile parts, grapes, figs, citrons, pomegranates and other fruits are produced. Wheat is the main crop; maize and rice are also grown, and some attention is given to the rearing of mules, asses, goats, cattle and sheep; while the Alter breed of horses, named after the villages of Alter do Chão and Alter Pedroso (3,971), near Portalegre, is often accounted the best in the country. Agriculture, however, is backward, the sparse population being mostly concentrated in the towns. Drovers of large swine are fed on the waste lands, affording excellent hams. The mineral wealth of Alentejo, little exploited, includes copper and iron mines and marble quarries. Local industries include preparation of exceptionally fine olive oil, and the manufacture of cloth, pottery and leather. Alentejo is traversed by two main lines of railway, the Madrid-Badajoz-Lisbon and Lisbon-Faro. For administrative purposes the province is divided into the districts of Portalegre in the north, Evora in the central region and Beja in the south.

ALEPPO, a district and city in Syria. Under Turkish rule the name of the city (Halab) was borne also by a *vilayet* and a *sanjak*. With the British occupation of the area in 1918 an Arab military governor was installed and when France took possession of Syria under the League of Nations mandate Aleppo gave its name to one of the five *états* (territories) into which Syria was divided. In 1925 the *états* of Aleppo and Damascus were united to form one *état*, Syria, with seven *sanjaks*, of which Aleppo is one. Tobacco is largely grown and the district is one of the centres of the silk industry. Wheat and a small quantity of hemp are also grown.

The city stands on a plateau in the valley of the Kuwaik (anc. Chaly) 10m. above its dissipation in the salt marsh El-Matkh.

BY COURTESY OF THE METROPOLITAN MUSEUM OF ART

TEKYAH AT ALEPPO OF ABU BEKR, FATHER-IN-LAW OF MOHAMMED
Situated at the northern end of the city, this tekyah, or religious house for the accommodation and ceremonial rites of dervishes, is representative of the many religious buildings in Aleppo

History.—As early as 2000 B.C., when the "kings of Aleppo held a great kingdom," the Hittite monarch Murshil I. swept down through the Taurus passes and took the city. The Pharaoh Thutmose III. seized it (1490 B.C.) when he marched north, "laying waste the settlements of the foe of wretched Naharin." About the middle of the 15th century its king allied himself with the king of Hanigalbat, but the Hittite Tudhalia I. defeated them and sacked Aleppo. The city recovered only to fall victim to his successors Hattushil and Subbiluliuma, the latter of whom made Telipinush, his son, its king. The region became the battleground between Egypt and the Hittites and the struggle for its possession is reflected in the preface to the treaty (c. 1310 B.C.) between Murshil III. and Rimisharma, king of Aleppo. At the battle of Kadesh on the Orontes (1288 B.C.), where Ramses II. barely escaped defeat, a king of Aleppo took part on the Hittite side and was all but drowned. The Egyptians have depicted on their monuments "the wretched chief of Aleppo turned upside down by his soldiers after his majesty had hurled him into the water." In 854 B.C. Shalmaneser II. of Assyria visited the city and sacrificed to Adad. Seleucus Nicator (312-280 B.C.) enlarged Aleppo and named it Beroea, after the Macedonian city. In 164 B.C. Menelaus, the fomenter of war with the Asmonians, was put to death by being thrust down into a tower filled with embers, a form of execution peculiar to the place. The name Halab reappears with the Arab conquest of Syria (A.D. 638), when the city was occupied without opposition by Abu 'Ubaidah. The Hamdanid Saif ed-Daulah (A.D. 936-967), who called himself "king of Aleppo," made Halab his residence, but the Byzantine Nicephorus Phocas surprised and sacked the city (962) but failed to capture the citadel. It was temporarily occupied by John Zimisces, emperor of Byzantium in 974. Shortly afterwards it received and acknowledged the Egyptian Fatimides, and twice, from 1038-42 and 1058-60, Egyptian troops garrisoned the town. From 1090-1117 it formed part of the Seljuk dominion. Then succeeded the unsettled times of the Crusades. The Crusaders, although they seized its territory, never occupied the city. They besieged it in

1118 and again in 1124 (Baldwin II.), when, after four months, it was reduced to the utmost extremity before being relieved by an army from Mosul. The 12th century saw three serious earthquakes, 1114, 1139, and the most serious of all, 1170, after which the city had to be rebuilt by Nūr ed-Dīn. Benjamin of Tudela visited it in 1173. Saladin made it his northern base and stronghold against the Crusading princes of Antioch (1183). The Tatar invasions of the 13th and 14th centuries engulfed it, and with the rest of Syria it came under the Mameluke sway at the end of the 13th century. Aleppo surrendered to Tamerlane when he made an incursion into Syria (1400-01). The Mameluke rule in Syria was finally overthrown by the triumph of the Ottoman Turks under Selīm I. in 1517, the decisive battle being at Merj Dābik, a day's journey west of Aleppo. From the 16th to the 19th centuries it remained in Turkish hands. In the latter part of the 18th and the beginning of the 19th century it suffered grievously from internal feuds (in which the Janissaries took an active part), which were exploited by the Ottoman governors for their own ends. Earthquakes in 1822 and 1830 and visitations of cholera in 1823, 1827 and 1832 left the city a wreck and its population greatly diminished. It could offer but feeble resistance to the army of Mohammed Ali of Egypt in 1833. It then became the centre of Egyptian domination in Syria until it was restored to the Turks in 1840. Tumults and massacres of Christians occurred in 1850 and 1862. On Oct. 26, 1918, it was occupied by the 5th cavalry division of the Egyptian expeditionary force. Aleppo showed hostility to the French army of occupation when it replaced the British in 1920.

The Modern City.—The population of the modern city is about 200,000. The older portion is contained within a wall with nine gates (*bāb*). The Europeans reside mainly in the Kittāb and 'Aziziyah and the Jews in the Bahsītah. The citadel occupies what appears to be an artificial mound in the centre of the town and is surrounded by a dry moat. Two of the mosques have a special interest, the Zakariyah, in which is a tomb reputed to be that of Zacharias, father of John the Baptist, and the Kikanah into the wall of which is built a basalt block with Hittite inscription. Aleppo is the mart for north Syria. It is renowned for the beauty of its *sūqs* (market-places) and adornment of its dwellings, and it is relatively clean and well paved. Its bazaars and khans (in which its wholesale trade is concentrated) are unusually large. Gardens extend in a narrow strip for miles along the river and are much resorted to in summer. In winter frost and snow are not uncommon, but the climate is healthy despite the prevalence of the Aleppo boil or button, which develops into an ulcer, leaving eventually an unsightly scar.

Trade.—Aleppo formerly derived its importance from its commanding position on the trade route between Europe and Persia and India. One of the first provincial factories and consulates of the British Turkey (Levant) company was established in it in the reign of James I., and a British agent had been in residence there even in Elizabeth's time. It was connected with Baghdad, the western outpost of the East India company, by a private postal service. The first blow was struck at this trade by the discovery of the Cape route to India, the second by the opening of the land route, through Egypt to the Red sea, and the third and final one by the making of the Suez canal. Aleppo is now connected by rail with its Mediterranean port, Alexandretta, via the Baghdad railway (1920), and with Tripoli via Homs (1909). A branch line to Alexandretta via Antioch, which would halve the time of rail transport, is projected. Meanwhile there is a rapidly extending motor transport traffic between the two places. The industries of Aleppo include starch, soap, textiles (cotton, silk and fine stuffs), carpet weaving, dye and copper-work. It exports, in addition to its manufactures, cereals, tobacco, pistachio nuts, wool, cotton and *semm* (melted butter packed in skins). It is one of the chief markets for sheep and a centre of the wool trade. Trade with Anatolia has diminished since the erection of the frontier.

ALES or ALESIVS, ALEXANDER (1500-65), Scottish reformer, was born at Edinburgh, April 23, 1500. As canon of the collegiate church of St. Andrews he opposed the Reformers, but was converted by the arguments and the courageous death of Patrick Fern in 1538. He escaped to Germany and at Wittenberg signed the Augsburg Confession. He went to England in 1535, and was well received by Cranmer and Thomas Cromwell, but the statute of Six Articles (1539) drove him back to Germany. He was professor of theology at Leipzig at the time of his death (March 17, 1565).

Alesius was the author of a large number of exegetical, dogmatic and polemical works, of which over 20 are mentioned by Bale in his *List of English Writers*. In his controversial works he upholds the synergistic views of the Scottish theologian John Major. He wrote an appeal to his native land in *Cohortatio ad Concordiam Pietatis, missa in Patriam suam* (1544), which had the express approval of Luther, and a *Cohortatio ad Pietatis Concordiam ineundam* (1559).

The best early account of Alesius is the *Oratio de Alexandro Alesio* of Jacob Thomasius (April 1661), printed in his *Orationes* (No. xiv., Leipzig, 1683); the best modern account is by Dr. A. W. Ward in the *Dictionary of National Biography*. See also A. F. Mitchell's introduction to Gau's *Richt Vay* (Scottish Text Society, 1888).

ALÈS, South France, capital of an arrondissement in the department of Gard, 25m. N.N.W. of Nîmes on the P.L.M. railway. Pop. (1926) 29,749. The town is at the foot of the Cévennes, on the left bank of the Gardon, which half surrounds it. The proximity of the high plateau—a region of social difficulty and poverty—made Alès in the 16th century an important Huguenot centre. In 1629 it was taken by Louis XIII. A bishopric was established here in 1694 but suppressed in 1790. The church of St. Jean is a heavy building of the 18th century. Alès has associations with Pasteur and Dumas. The town is one of the most important markets for raw silk and cocoons in the south of France, and the Gardon supplies power to numerous silk-mills. It is also the centre of a mineral field, which yields coal, iron, silver, zinc and antimony; its blast-furnaces, foundries, tanneries, distilleries, glass-works and engineering works afford employment to many workmen.

Alès has a tribunal of commerce, a board of trade-arbitrators, and a school of mines. In 1926 the name of the town was changed from Alais to Alès.

ALESIA, the ancient name for a hill in the department of Côte d'Or, France, now Alise-Ste-Reine. (Pop. of commune [1926] 476.) The site was important in early times. Here Vercingetorix, the Gaulish national leader, was besieged by Caesar in 52 B.C.—the former's surrender leading to the final conquest of Gaul. The native leader is commemorated by a statue on Mt. Auxois. The discovery of the remains of a town and temple in 1906-10 shows that the site remained important through Gallo-Roman times. The ground plan of a large mediaeval structure which has been revealed by excavations, suggests the continuity of interest in this hill-top site into the middle ages. Its situation on a hill top, off modern lines of communication has led to its decay. The region is visited annually by large numbers of tourists.

For account of Alesia see Déchelette *Manuel d'Archéologie*, II. 3, pp. 958 ff. 1914 (bibl.).

Siege of Alesia, was the climax of the great revolt which endangered Julius Caesar's conquest of Gaul. He was temporarily back in Italy, after his expeditions across the Rhine and the Channel, when word came of the general rising (end of 53 B.C.) of most of the Gallic tribes under Vercingetorix, a chieftain of the Arverni (modern Auvergne). Fortunately for Caesar it came before he was entangled in the Civil War, and by rapid counter-measures, involving arduous mid-winter marches, he partially restored the situation. But guerilla warfare on a far-reaching scale undermined his efforts, he was forced to abandon his siege of

Gergovia (near modern Clermont-Ferrand) Vercingetorix's own town, and through the Aedui joining in the revolt, was cut off from his base in the south. In this critical situation Caesar first moved to effect a junction with Labienus's detachment, which had with difficulty returned from an abortive attempt on Lutetia (modern Paris), and then sought a line of retreat back to his base, taking an easterly route. But Vercingetorix, emboldened by success to discard pure harassing strategy, moved to intercept him near modern Langres, and surprised him on the march. The Romans succeeded in repulsing the attack, and Vercingetorix retreated to a fortified camp at Alesia (probably Mont Auxois, near modern Dijon). Thus assured of his communications being free, Caesar decided to lay siege to Alesia, which now held the soul as well as a large part of the body of the revolt. He completely invested the position, surrounding it with lines of contravallation, ten miles in perimeter and fortified with all the science of Roman field engineering, and outside these he built lines of circumvallation to protect himself from any relieving forces. These soon gathered in great force but inadequate organization, and their onsets were repulsed until, finding that Vercingetorix's sortie was equally ineffectual, they retired. The third and last attempt, made at the weakest spot—a hill which could not be included in the lines of circumvallation—was barely withstood, but with its failure Vercingetorix was forced, from lack of supplies, to surrender. Thereafter, although isolated outbreaks occurred, the Roman grip upon Gaul was not again seriously threatened.

ALESSANDRI, ALESSANDRO (ALEXANDER AB ALEXANDRO) (1461–1523), Italian jurist, was born at Naples about the year 1461. His work entitled *Dies Geniales* appeared at Rome in 1522, and was constructed after the model of the *Noctes Atticae* of Aulus Gellius, and the *Saturnalia* of Macrobius. It consists of a confused mass of heterogeneous materials relating to philology, antiquities, law, dreams, spectres, etc. and is characterized by considerable credulity.

ALESSANDRIA, capital of province of same name and episcopal see, Piedmont, Italy, on the river Tanaro, 57m. S.E. of Turin by rail. Pop. (1921) 41,021 (town), 78,278 (commune). Founded in 1168 for defence against the marquis of Monferrato and the town of Pavia, it was besieged in 1174 by Frederick Barbarossa for six months without success. The Lombard League then included it among the allied cities and named it Alessandria, after Pope Alexander III. It was ceded to Savoy by the Peace of Utrecht in 1713, and its citadel was begun in 1728. Fortifications were made during the French occupation (1800–1814) after Marengo; they were destroyed by the Austrians (1815) and were later rebuilt, but are now obsolete, though Alessandria is still an important fortress. The citadel is on the left bank of the Tanaro, the town on the right. It has various manufactures, especially felt hats, is a commercial centre and the focus of railway lines to Turin via Asti, to Valenza (thence to Vercelli, Mortara—for Novara or Milan—and Pavia), to Tortona, to Novi, to Acqui and to Bra.

ALESSI, GALEAZZO (1512–1572), Italian architect, was born at Perugia, and was probably a pupil of Caporali. He was an enthusiastic student of ancient architecture, and his style gained for him a European reputation. Genoa is indebted to him for a number of magnificent palaces, and his art may be studied in the churches of San Paolo and Santa Vittoria at Milan, in certain parts of the Escorial, and in numerous churches and palaces throughout Sicily, Flanders, and Germany.

See Rossi, *Di Galeazzo Alessi memorie* (Perugia, 1873).

ALETHIOLOGY, an uncommon expression for the doctrine of truth (Gr. ἀλήθεια, truth) used by Sir William Hamilton in his philosophic writings when treating of the rules for the discrimination of truth and error. The term was first used by Lambert in his *New Organon*, 1764.

ALETRIUM (mod. ALATRI), a town of the Hernici, about 6m. due N. of Frusino, Italy, mentioned 306 B.C. for fidelity to Rome. In Cicero's time it was a *municipium*, and continued in this position throughout the imperial period. Finely preserved fortifications of blocks of local limestone have an outer circuit of about 2½m. An embanking wall, the rule in the cities of this part, has a

maximum height of about 30ft. Two gates and three posterns are to be found. A central hill (1,647ft.) was the citadel. Fortifications of three periods can be traced; the last, perhaps a little more recent than the city wall, is best preserved. A flat surface was formed partly by smoothing off the rock and partly by the erection of huge terrace walls which rise to a height of over 50ft., enclosing a roughly rectangular area of 235 by 115yds. Two approaches to the citadel pass through the wall.

ALEURITES (Gr. ἀλευρίτης, pertaining to ἄλευρον, ground meal, from ἀλεῖν, to grind), a genus of trees belonging to the family Euphorbiaceae. *Aleurites triloba* is widely cultivated throughout the tropical and sub-tropical parts of the world for its fruit, which is about the size of a walnut, and contains several seeds which are rich in oil. The oil is extracted and used for food and light; it is known in India as *kekuna*, and the tree as the candle-nut. In the Sandwich islands the nuts are strung upon strips of wood and used as torches. The oil is exported to Europe for candle-making. *A. cordata* flourishes in China, where it is known as the varnish-tree.

ALEUT (äl'ë-ōōt), a native of the Aleutian islands and part of the Alaska peninsula, a branch of the Eskimo stock. They differ from the Eskimo in their brachycephaly, but resemble them in features, and their language, though well differentiated, is fundamentally Eskimo. Their culture, too, is from the same source, though adapted to a raw and wet rather than an extremely cold environment. They came under Russian control, became Orthodox Christians, are now hybrid in blood as well as customs, and reduced in numbers. In 1834 there remained 2,200; in 1900, 1,700.

ALEUTIAN ISLANDS, a chain of small islands situated in the Northern Pacific ocean, and extending about 1,200m. westward from the extremity of the Alaskan peninsula toward the peninsula of Kamchatka; they constitute part of the Territory of Alaska, U.S.A. The islands, of which an alternative collective name is the Catherine archipelago, comprise four groups—the Fox, Andreanof, Rat and Near islands. They are all included between 52° and 55° N. and 172° E. and 163° W.

The axis of the archipelago near the mainland of Alaska has a south-west trend, but near the 179th meridian its direction changes to the north-west. This change of direction corresponds to a curve in the line of volcanic fissures which have contributed their products to the building of the islands. The island chain is really a western continuation of the Aleutian range on the mainland. The great majority of the islands bear evident marks of volcanic origin, and there are numerous volcanic cones on the north side of the chain, some of them active; many of the islands, however, are not wholly volcanic, but contain crystalline or sedimentary rocks, and also amber and beds of lignite. The coasts are rocky and surf-worn and the approaches are exceedingly dangerous, the land rising immediately from the coasts to steep, bold mountains.

The climate of the islands is oceanic, with moderate and fairly uniform temperatures and heavy rainfall. Fogs are almost constant. The summers are much cooler than on the mainland at Sitka (*q.v.*), but the winter temperature of the islands and of south-eastern Alaska is very nearly the same. The mean annual temperature for Unalaska, the most important island of the group, is about 38° F. The growing season lasts about 135 days, from early in May till late in September, but agriculture is limited to the raising of a few vegetables. The islands are practically destitute of trees, but are covered with a luxuriant growth of herbage, including grasses, sedges and many flowering plants. Attempts have been made to raise sheep and reindeer on the islands, but the industry is still in its infancy with some uncertainty as to future results. The principal occupations of the natives have always been fishing and hunting, and the women weave basketry of exquisite fineness. From the end of the 18th century the Russian fur traders had settlements here for the capture of the seal and the sea otter and the blue and the Arctic fox. Under the American régime seal fishing off the Aleutians, save by the natives, has never been legal, but the rapid depletion of animals has threatened the Aleuts (as the natives are commonly called) with starvation. In recent years the raising of foxes, especially of blue fox, has been

conducted quite extensively throughout the islands and with a fair measure of success. This industry furnishes employment to many natives. Fish and sea-fowl are extremely abundant.

The natives are rather low in stature, but plump and well shaped, with short necks, swarthy faces, black eyes and long black hair. They are a branch of the Esquimauan family, but differ greatly from the Eskimo of the mainland in language, habits, disposition and mental ability. They were good fighters until they were cowed by the treatment of the Russians, who practically reduced them to slavery. Christianity is recognized in the form of the Greek Orthodox Church.

In dress and mode of life they have adopted outwardly civilized customs.

It is stated that before the advent of the Russians there were 25,000 Aleuts (*q.v.*) on the archipelago, but that the barbarities of the traders nearly extinguished the native population. The total population of the archipelago in 1920 was 1,080. The principal settlements are on the Unalaska Islands. Of these Unalaska, the oldest, settled in 1760-75, has a custom house, a Russian-Greek church, and a Methodist mission and orphanage, and is the headquarters for a considerable fleet of United States coast guard vessels which patrol the sealing grounds of the Pribilofs; adjacent is Dutch Harbor. The Commander Islands group near the Asiatic coast is geographically, but since the acquisition of the Russian possessions in America not politically, a part of the Aleutian system.

In 1741 the Russian Government sent out Vitus Bering, a Dane, and Alexei Chirikov, a Russian, in the ships "Saint Peter" and "Saint Paul" on a voyage of discovery in the northern Pacific. After the ships were separated by a storm, Chirikov discovered several eastern islands of the Aleutian group, and Bering discovered several of the western islands, finally being wrecked and losing his life on the island of the Commander group that now bears his name. The survivors of Bering's party reached Kamchatka in a boat constructed from the wreckage of their ship, and reported that the islands were rich in fur-bearing animals. Siberian fur hunters at once flocked to the Commander Islands and gradually moved eastward across the Aleutian islands to the mainland. In this manner Russia gained a foothold on the north-western coast of North America. The Aleutian islands consequently belonged to Russia, until that country in 1867 transferred to the United States all its possessions in America.

ALEWIFE (*Pomolobus pseudoharengus*), a fish allied to the shad (*q.v.*), which spawns in great numbers in the tidal parts of the rivers of eastern North America, from the St. Lawrence southwards, during the spring. It grows to a length of a foot and is an important food fish.

ALEXANDER, the name of eight Popes:

ALEXANDER I. was bishop of Rome from about 106 to 115. He has been identified, without any foundation, with Alexander, a martyr of the Via Nomentana, whose day is May 3.

ALEXANDER II. (Anselmo Baggio), Pope from 1061 to 1073, was a native of Milan. As bishop of Lucca he seconded the efforts of Hildebrand (afterwards Gregory VII.) for the suppression of simony and the enforcement of the celibacy of the clergy. By Hildebrand's influence he was elected Pope, but the German court nominated Cadalus, bishop of Parma, who was proclaimed at the council of Basel as Honorius II., and marched to Rome. Alexander's ultimate victory over his rival was due to Hildebrand.

ALEXANDER III. (Orlando Bandinelli), Pope from 1159 to 1181, was a Siennese, and teacher of canon law in Bologna and author of the *Stroma*, or the *Summa Magistri Rolandi*, one of the earliest commentaries on the Decretum Gratiani and of *Sentences*, based on the *Introductio ad theologiam* of Abelard. In 1153 he became papal chancellor, and was the leader of the cardinals opposed to Frederick Barbarossa. On Sept. 7, 1159, he was chosen to succeed Adrian IV., a minority of the cardinals, however, electing the cardinal priest Octavian, who assumed the name of Victor IV. This antipope, and his successors Paschal III. (1164-68) and Calixtus III. (1168-78), had the imperial support; but after the defeat of Legnano, Barbarossa finally (in the peace of Venice,

1177) recognized Alexander as Pope. On March 12, 1178, Alexander returned to Rome, which he had been compelled to leave twice, from 1162 to 1165, and again in 1167. The first period he spent in France, the latter chiefly in Gaeta, Benevento, Anagni and Venice. In March 1179 Alexander held the third Lateran synod, reckoned by the Roman Catholic Church as the 11th oecumenical council; its acts embody among them the present law

POPE ALEXANDER III. BESTOWING THE SWORD UPON DOGE ZIANI OF VENICE. FROM THE FRESCO IN THE PALAZZO PUBBLICO AT SIENA, BY SPINELLO ARETINO (1333-1410)

requiring that no one may be elected Pope without the votes of two-thirds of the cardinals. This synod marks the summit of Alexander's power. Besides checkmating Barbarossa, he had humbled Henry II. of England in the affair of Thomas Becket, he had confirmed the right of Alphonso I. of Portugal to the crown, and even as a fugitive had enjoyed the favour and protection of Louis VII. of France. Nevertheless, soon after the close of the synod the Roman republic forced Alexander to leave the city, which he never re-entered; and on Sept. 29, 1179, some nobles set up the antipope Innocent III. By the judicious use of money, however, Alexander got him into his power, so that he was deposed in Jan. 1180. In 1181 Alexander excommunicated William the Lion of Scotland and put the Kingdom under the interdict. The great Pope died at Civita Castellana on Aug. 30, 1181.

See Herzog-Hauck, *Realencyklopädie*, 3rd ed. i. 340-44; Wetzzer and Welte, *Kirchenlexikon*, 2nd ed., 1481. The most elaborate biography is H. Reuter, *Geschichte Alexanders III. und der Kirche seiner Zeit* (2nd ed., Leipzig, 1860).

ALEXANDER IV. (Rinaldo), Pope from 1254 to 1261, was a member of the family of the counts of Segni. On the death of Innocent IV. he was elected Pope at Naples on Dec. 12, 1254. He is described as a stout man, kindly, cheerful, but of no great brilliancy. He succeeded Innocent IV. as guardian of Conradin, the last of the Hohenstaufen, to whom he promised benevolent protection; but in less than a fortnight he conspired against him

and bitterly opposed Conradin's uncle Manfred. Alexander fulminated with excommunication and interdict against the party of Manfred, but in vain; nor could he enlist the kings of England and Norway in a crusade against the Hohenstaufen. Rome itself became too Ghibelline for the Pope, who withdrew to Viterbo, where he died on May 25, 1261. His pontificate was signalized by efforts to unite the Greek and Latin churches by the establishment of the Inquisition in France, by favours to the mendicant orders, and by an attempt to organize a crusade against the Tatars.

The registers of Alexander IV. are published by Bourel de la Roncière and others in the *Bibliothèque des Écoles françaises d'Athènes et de Rome* (Paris, 1895 et seq.).

ALEXANDER V. (Peter Philargès), Pope from 1409 to 1410, was born in Crete of unknown parents and entered the order of St. Francis. He was a member in turn of the Universities of Oxford and Paris, and finally settled in Lombardy, where, thanks to the favour of Gian Galeazzo Visconti, he became eventually archbishop of Milan. Created cardinal by Innocent VII., he worked for the realization of the union of the Church, in spite of the two rival popes. He was one of the promoters of the council of Pisa, and after that assembly had declared Gregory XII. and Benedict XIII. deposed, the cardinals elected Alexander as Pope (June 26, 1409), thus adding a third to the number of rival pontiffs. During his short reign of ten months Alexander V.'s aim was to extend his obedience with the assistance of France. He died suddenly at Bologna in the night of May 3-4, 1410, and it was suspected, though without proof, that he had been poisoned.

ALEXANDER VI. (Rodrigo Borgia), (1431-1503), pope from 1492 until his death, is the most memorable of the corrupt and secular Popes of the Renaissance. He was born, Jan. 1, 1431, at Xativa, near Valencia in Spain. He assumed the name of his mother's family, Borgia or Borja, on the elevation of his maternal uncle to the papacy as Calixtus III. (April 8, 1455). He studied law at Bologna, and after his uncle's election he was created successively bishop, cardinal and vice-chancellor of the church. He served in the Curia under five Popes, and acquired much administrative experience, influence and wealth, although no great power; he was economical in his habits, though on occasion he displayed great splendour and lived in a fine palace. Of his many mistresses, the one for whom his passion lasted longest was Vannozza (Giovanna) dei Cattani, born in 1442, and wife of three successive husbands. The connection began in 1470, and she bore him children whom he openly acknowledged as his own: Giovanni, afterwards Duke of Gandia (born 1474), Cesare, (born 1476), Lucrezia (born 1480), and Goffredo or Giuffrè (born 1481 or 1482). Before his elevation to the papacy, Cardinal Borgia's passion for Vannozza diminished. Her place was filled by the beautiful Giulia Farnese (Giulia Bella), wife of an Orsini, but his love for his children by Vannozza remained as strong as ever, and proved, indeed, the determining factor of his whole career. He lavished vast sums on them and loaded them with every honour.

On the death of Pope Innocent VIII., the three likely candidates for the Holy See were Cardinals Borgia, Ascanio Sforza and Giuliano della Rovere. Borgia, by his great wealth, succeeded in buying the largest number of votes, including that of Sforza, and was elected Aug. 10, 1492, assuming the name of Alexander VI. At first his reign was marked by a strict administration of justice and an orderly method of Government, in contrast with the anarchy of the previous pontificate, as well as by great outward splendour. But he indulged his unbridled passion for endowing his relatives at the expense of the Church and of his neighbours. Cesare, then a youth of 16 and a student at Pisa, was made archbishop of Valencia, his nephew Giovanni received a cardinal's hat, and for the Duke of Gandia and Giuffrè the pope proposed to carve fiefs out of the Papal States and the Kingdom of Naples. Among the fiefs destined for the Duke of Gandia were Cervetri and Anguillara, lately acquired by Virginio Orsini, head of that powerful and turbulent house, with the pecuniary help of Ferdinand of Aragon, king of Naples (Don Ferrante). This brought Ferdinand of Aragon into conflict with Alexander, who consequently made an alliance with the king's enemies, especially the Sforza family, lords of Milan.

In this he was opposed by Cardinal della Rovere, whose candidature for the papacy had been backed by Ferdinand. Della Rovere, feeling that Rome was a dangerous place for him, fortified himself in his bishopric of Ostia at the Tiber's mouth, while Ferdinand allied himself with Florence, Milan, Venice, and the Pope formed a league against Naples (April 25, 1493) and prepared for war. Ferdinand appealed to Spain for help; but Spain was anxious to be on good terms with the pope to obtain a title over the newly discovered continent of America, and could not afford to quarrel with him.

Alexander meditated great marriages for his children. Lucrezia had been married to the Spaniard Don Gasparo de Procida, but the union was annulled, and in 1493 she was married to Giovanni Sforza, lord of Pesaro, the ceremony being celebrated at the Vatican with unparalleled magnificence. But in spite of the splendours of the court, the condition of Rome became every day more deplorable. The city swarmed with Spanish adventurers, assassins, prostitutes and informers; murder and robbery were committed with impunity, heretics and Jews were admitted to the city on payment of bribes, and the pope himself shamelessly cast aside all show of decorum, living a purely secular and immoral life, and indulging in the chase, dancing, stage plays and indecent orgies. One of his boon companions was Jem, the brother of the Sultan Bayezid, detained as a hostage.

Alexander carried on a double policy, always ready to seize opportunities to aggrandize his family. But through the intervention of the Spanish ambassador he made peace with Naples in July 1493 and also with the Orsini. In order to dominate the Sacred College more completely he created 12 new cardinals, among them his own son Cesare, then only 18 years old, and Alessandro Farnese, the brother of Giulia Bella, one of the Pope's mistresses. On Jan. 25, 1494, Ferdinand died and was succeeded by his son Alphonso II. Charles of France now advanced formal claims on the Kingdom, and Alexander authorized him to pass through Rome ostensibly on a crusade against the Turks, without mentioning Naples. But when the French invasion became a reality he was alarmed, recognized Alphonso as king, and concluded an alliance with him in exchange for various fiefs to his sons (July 1494). Preparations for defence were made; but the pope was unable to defend Rome, and came to terms with the invader. Charles conquered Naples and was crowned king there on May 12, 1495, but a reaction set in. A league of the principal powers assembled a force in Italy which threatened Charles's retreat. He withdrew to France, and Ferdinand II., Alphonso's son, was established at Naples with Spanish help.

Alexander availed himself of the defeat of the French to break the power of the Orsini. Virginio Orsini, who had been captured by the Spaniards, died a prisoner at Naples, and the pope confiscated his property. But the rest of the clan still held out, and the papal troops sent against them under Guidobaldo, Duke of Urbino, and the Duke of Gandia were defeated at Soriano (Jan. 1497). Peace was made through Venetian mediation, the Orsini paying 50,000 ducats in exchange for their confiscated lands. The Orsini still remained very powerful, and Alexander could count on none but his 3,000 Spaniards.

Now occurred the first of those ugly domestic tragedies for which the house of Borgia remained infamous. On June 14 the Duke of Gandia, lately created Duke of Benevento, disappeared; the next day his corpse was found in the Tiber. Alexander, overwhelmed with grief, shut himself up in Castle St. Angelo. The rumour spread about that Cesare, the Pope's second son, was the author of the deed, and the search for the assassin then ceased. No doubt Cesare, who contemplated quitting the Church, was inspired by jealousy of Gandia's influence with the Pope. Violent and revengeful, he now became the most powerful man in Rome, and even his father quailed before him.

As he needed funds to carry out his various schemes, the Pope began a series of confiscations, of which one of the victims was his own secretary, in order to enrich him. The process was a simple one: any cardinal, nobleman or official who was known to be rich would be accused of some offence; imprisonment and perhaps murder followed at once, and then the confiscation of his

property. The disorganization of the Curia was appalling, the sale of offices became a veritable scandal, the least opposition to the Borgia was punished with death, and even in that corrupt age the state of things shocked public opinion. The story of Alexander's relations with Savonarola is narrated under the latter heading; it is sufficient to say here that the Pope's hostility was due to the friar's outspoken invectives against papal corruption and to his appeals for a General Council. Alexander, although he could not get Savonarola into his own hands, browbeat the Florentine Government into condemning the reformer to death (May 23, 1498).

The Pope was unable to maintain order in his own dominions; the houses of Colonna and Orsini were at open war with each other, but after much fighting they made peace on a basis of alliance against the Pope. He had annulled Lucrezia's marriage with Sforza in 1497, and arranged her marriage to the Duke of Bisceglie, a natural son of Alphonso of Aragon. Cesare, who renounced his cardinalate, was sent on a mission to France at the end of the year, bearing a bull of divorce for the new king, Louis XII., in exchange for which he obtained the duchy of Valentinois (hence his title of Duca Valentino) and a promise of material assistance in his schemes to subjugate the feudal princelings of Romagna; he married a princess of Navarre. In spite of the remonstrances of Spain and of the Sforza, Alexander allied himself with France in Jan. 1499 and was joined by Venice. By the autumn Louis was in Italy and expelled Lodovico Sforza from the Milanese. In order to consolidate his possessions still further now that French success seemed assured, the Pope determined to deal drastically with Romagna, which although nominally under papal rule was divided into a number of practically independent lordships on which Venice, Milan and Florence cast hungry eyes.

Cesare, nominated *gonfaloniere* of the Church, and strong in French favour, proceeded to attack the turbulent cities one by one (for details see BORGIA, CESARE). But the expulsion of the French from Milan and the return of Lodovico Sforza interrupted his conquests, and he returned to Rome early in 1500. This year was a jubilee year, and crowds of pilgrims flocked to the city from all parts of the world, bringing money for the purchase of indulgences, so that Alexander was able to furnish Cesare with funds for his enterprise. In the north the pendulum swung back once more and the French reoccupied Milan in April, causing the downfall of the Sforza much to Alexander's gratification.

But there was no end to the Vatican tragedies, and in July the Duke of Bisceglie, whose existence was no longer advantageous, was murdered; this left Lucrezia free to contract another marriage. The Pope, ever in need of money, now created 12 new cardinals, from whom he received 120,000 ducats; and fresh conquests for Cesare were considered. But while a crusade was talked of, the real object was central Italy, and in the autumn Cesare, favoured by France and Venice, set forth with 10,000 men to complete his interrupted enterprise. On his return to Rome (June 1501) Cesare was created Duke of Romagna. Louis XII. now concluded a treaty with Spain for the division of the Neapolitan kingdom, which was ratified by the Pope on June 25, Frederick being formally deposed. The French army proceeded to invade Naples, and Alexander took the opportunity, with the help of the Orsini, to reduce the Colonna to obedience. In his absence he left Lucrezia as regent, offering the astounding spectacle of a Pope's natural daughter in charge of the Holy See. Shortly afterwards he induced Alphonso d'Este, son of the Duke of Ferrara, to marry her (Jan. 1502).

As France and Spain were quarrelling over the division of Naples and the Campagna barons were quiet, Cesare set out once more in search of conquests (see BORGIA, CESARE). As soon as Alexander heard the news of Cesare's successes (1502) he decoyed Cardinal Orsini to the Vatican and cast him into a dungeon, where he died. His goods were confiscated, his aged mother was turned into the street, and numbers of other members of the clan in Rome were arrested, while Giuffrè Borgia led an expedition into the Campagna and seized their castles. Thus the two great houses of Orsini and Colonna, who had long fought for predominance in Rome, and often flouted the Pope's authority,

were subjugated. Three more high personages fell victims to the Borgias' greed this year, viz., Cardinal Michiel, who was poisoned in April, and J. da Santa Croce, who had helped to seize Cardinal Orsini and Troches or Troccio, one of the family's most faithful assassins; all these murders brought immense sums to the pope. About Cardinal Ferrari's death there is more doubt; he probably died of fever, but the Pope confiscated his goods.

The war between France and Spain for the possession of Naples dragged on, and Alexander was ever intriguing, ready to ally himself with whichever power promised at the moment most advantageous terms. Cesare was preparing for another expedition into central Italy in July 1503, when, in the midst of all these projects and negotiations both he and his father were taken ill with fever. The occurrence was, of course, attributed to poison, although it was merely the result of malaria, at that time very prevalent in Rome. On Aug. 18 Alexander died at the age of 72. His death was followed by scenes of wild disorder, and Cesare, being himself ill, sent Don Michelotto, his chief bravo, to seize the Pope's treasures before the demise was publicly announced. Alexander's successor on the chair of St. Peter was Francesco Todeschini-Piccolomini, who assumed the name of Pius III.

Alexander VI. has become almost a mythical character, and countless legends and traditions are attached to his name. His career shows no great political ideas, and his one thought was family aggrandizement. While it is unlikely that he meditated making the papacy hereditary in the house of Borgia, he certainly gave away its temporal estates to his children as though they belonged to him. The secularization of the church was carried to a pitch never before dreamed of, and it was clear to all Italy that he regarded the papacy as an instrument of worldly schemes with no thought of its religious aspect. During his pontificate the church was brought to its lowest level of degradation. The condition of his subjects was deplorable, and if Cesare's rule in Romagna was an improvement on that of the local tyrants, the people of Rome have seldom been more oppressed than under the Borgia. Alexander was not the only person responsible for the general unrest in Italy and the foreign invasions, but he was ever ready to profit by them. Even if we do not accept all the stories of his murders and poisonings and immoralities as true, there is no doubt that his greed and his essentially vicious nature led him to commit a great number of crimes. For many of the misdeeds attributed to him, Cesare was responsible, but of others the Pope cannot be acquitted. The one pleasing aspect of his life is his patronage of the arts, and in his days a new architectural era was initiated in Rome with the coming of Bramante. Raphael, Michelangelo and Pinturicchio all worked for him and a curious contrast, characteristic of the age, is afforded by the fact that a family so steeped in vice and crime could take pleasure in the most exquisite works of art.

BIBLIOGRAPHY.—The chief contemporary authorities for this reign are: the diary of Alexander's master of ceremonies, Johannes Burchardus, edited by L. Thuasne (Paris, 1883-84), which is characterized by accuracy and by a candour often amounting to gross indecency; the despatches of Giustiniani, the Venetian ambassador, edited by P. Villari (Florence, 1876), which are based on the most accurate information; and Paolo Cappelli's "Diarii" in E. Alberi's *Relazioni*, series ii., iii. Among modern works the most important are: F. Gregorovius's *Geschichte der Stadt Rom* (3rd ed., Stuttgart, 1881), a work of immense research and admirable synthesis, giving a very unfavourable view of the Borgia; A. von Reumont's *Geschichte der Stadt Rom* (Berlin, 1867-70), also a valuable book; M. Creighton's *History of the Papacy* (London, 1897) is very learned and accurate, but the author is more lenient towards Alexander; F. Gregorovius's *Lucrezia Borgia* (Stuttgart, 1874) contains a great deal of information on the Borgia family; P. Villari's *Machiavelli* (English translation, new ed., 1892) deals with the subject at some length. Of the Catholic writers, L. Pastor, *Geschichte der Päpste* (Freiburg, i. B., 1886), should be consulted, for although the author tries to extenuate the pope to some extent, on the whole he is fair. See also Rafael Sabatini, *The Life of Cesare Borgia*; G. Portigliotti, *The Borgias*, trans. by Bernard Miall (1928).

ALEXANDER VII. (Fabio Chigi), Pope from 1655 to 1667, was born at Siena on Feb. 13, 1599. He was successively inquisitor at Malta, vice-legat at Ferrar and nuncio in Cologne (1639-51). Innocent X. subsequently made him cardinal-secretary of State. When Innocent died, Chigi, the candidate favoured by Spain, was

elected Pope on April 7, 1655. The Conclave believed he was strongly opposed to the nepotism then prevalent. In the first year of his reign Alexander VII. forbade his relations even to visit Rome; but in 1656 he gave them the best-paid civil and ecclesiastical offices, also palaces and princely estates. Alexander disliked business of State, preferring literature and philosophy; a collection of his Latin poems appeared at Paris in 1656 under the title *Philomathi Labores Iuveniles*. He also encouraged architecture, and in particular constructed the beautiful colonnade in the piazza of St. Peter's. He favoured the Jesuits, in their conflict with the Jansenists, forbade in 1661 the translation of the Roman Missal into French, and in 1665 canonized Francis of Sales. His pontificate was marked by protracted controversies with France and Portugal. He died on May 22, 1667.

ALEXANDER VIII. (Pietro Ottoboni), Pope from 1689 to 1691, was born in 1610 of a noble Venetian family, was created cardinal, and then successively bishop of Brescia and datary. The ambassador of Louis XIV. succeeded in procuring his election, Oct. 6, 1689, as successor to Innocent XI.; nevertheless, after months of negotiation Alexander finally condemned the declaration made in 1682 by the French clergy concerning the liberties of the Gallican church. Charities on a large scale and unbounded nepotism exhausted the papal treasury. He bought the books and manuscripts of Queen Christina of Sweden for the Vatican library. Alexander condemned in 1690 the doctrines of so-called philosophic sin, taught in the Jesuit schools. He died on Feb. 1, 1691.

AFTER A 17TH CENTURY ITALIAN MEDAL IN METROPOLITAN MUSEUM OF ART
PROFILE OF POPE ALEXANDER VII. ON AN EARLY ITALIAN MEDAL. HE CONSTRUCTED THE BEAUTIFUL COLONNADE IN THE PIAZZA OF ST. PETER'S

ALEXANDER I. (ALEKSANDER PAVLOVICH) (1777-1825), emperor of Russia, son of the grand-duke Paul Petrovich, afterwards Paul I., and Maria Fedorovna, daughter of Frederick Eugene of Württemberg, was born on Dec. 28, 1777. The strange contradictions of his character make Alexander one of the most interesting as he is one of the most important figures in the history of the 19th century. Autocrat and "Jacobin," man of the world and mystic, he was to his contemporaries a riddle which each read according to his own temperament. Napoleon thought him a "shifty Byzantine." To Metternich he was a madman to be humoured. Castlereagh gave him credit for "grand qualities," but said that he was "suspicious and undecided." His complex nature was, in truth, the outcome of the complex character of his early education. Reared in the free-thinking atmosphere of the court of Catherine II. he had imbibed from his Swiss tutor, Frédéric César de Laharpe, the principles of Rousseau's gospel of humanity; from his military governor, General Soltikov, the traditions of Russian autocracy; while his father had inspired him with his own passion for military parade. These contradictory tendencies remained with him through life, revealed in the fluctuations of his policy and influencing through him the fate of the world. Another element in his character discovered itself when in 1801 he mounted the throne over the body of his murdered father; a mystic melancholy liable at any moment to issue in extravagant action. At first, indeed, this exercised but little influence on his life. Young, impressionable, well-meaning and egotistic, Alexander plunged with all the ardour of youth into the task of realizing his political ideals. While retaining for a time the old ministers who had served and overthrown the emperor Paul, one of the first acts of his reign was to appoint a secret committee, called ironically the "Comité du salut public," consisting of young and enthusiastic friends of his own—Victor Gavovich Kochubey, Nikolai Nikolaevich Novosiltsov, Paul Alexandrovich Stroganov and Adam Czartoryski—to draw up a scheme of

internal reform. Their aims were far in advance of the possibilities of the time, and even after they had been raised to regular ministerial positions, but little of their programme could be realized. For Russia was not ripe for liberty; and Alexander, the disciple of the revolutionist Laharpe, was—as he himself said—but "a happy accident" on the throne of the tsars. He spoke, indeed, bitterly of "the state of barbarism in which the country had been left by the traffic in men." "Under Paul," he said, "three thousand peasants had been given away like a bag of diamonds. If civilization were more advanced, I would abolish this slavery, if it cost me my head."¹ But the universal corruption, he complained, had left him no men; and the filling up of the government offices, with Germans and other foreigners merely accentuated the sullen resistance of the "old Russians" to his reforms. That Alexander's reign, which began with so large a promise of amelioration, ended by riveting still tighter the chains of the Russian people was, however, mainly due to the defects of the tsar himself.

His love of liberty, though sincere, was in fact unreal. It flattered his vanity to pose before the world as the dispenser of benefits; but his theoretical liberalism was mated with an autocratic will which brooked no contradiction. "You always want to instruct me!" he exclaimed to Derzhavin, the minister of justice, "but I am the autocratic emperor, and I will this, and nothing else!" Moreover, with this masterful temper was joined an infirmity of purpose which ever let "I dare not wait upon I would," and seized upon any excuse for postponing measures the principles of which he had publicly approved. The codification of the laws initiated in 1801 was never carried out during his reign; nothing was done to improve the intolerable status of the Russian peasantry; the constitution drawn up by Speranski, and passed by the emperor, remained unsigned. Alexander, in fact, who, without being consciously tyrannical, possessed in full measure the tyrant's characteristic distrust of men of ability and independent judgment, lacked also the first requisite for a reforming sovereign, confidence in his people; and it was this want that vitiated such reforms as were actually realized. He experimented in the outlying provinces of his empire; and the Russians complained that, not content with governing through foreign instruments, he was conferring on Poland, Finland and the Baltic provinces benefits denied to themselves. In Russia, too, certain reforms were carried out; but they could not survive the suspicious interference of the autocrat and his officials. The newly created council of ministers, and the senate, endowed for the first time with certain theoretical powers, became in the end but the slavish instruments of the tsar and his favourites of the moment. The elaborate system of education, culminating in the reconstituted, or new-founded, universities of Dorpat, Vilna, Kazan and Kharkov, was strangled in the supposed interests of "order" and of orthodox piety; while the military colonies which Alexander proclaimed as a blessing to both soldiers and state were forced on the unwilling peasantry and army with pitiless cruelty. Even the Bible Society, through which the emperor in his later mood of evangelical zeal proposed to bless his people, was conducted on the same ruthless lines. The Roman archbishop and the Orthodox metropolitans were forced to serve on its committee side by side with Protestant pastors; and village popes were compelled to disseminate what they regarded as works of the devil.

Alexander's grandiose imagination was, however, more strongly attracted by the great questions of European politics than by attempts at domestic reform. On the morrow of his accession he had reversed the policy of Paul, denounced the League of Neutrals, made peace with England (April 1801), and opened negotiations with Austria. Soon afterwards, at Memel, he entered into a close alliance with Prussia. The development of this alliance was interrupted by the short-lived peace of Oct. 1801; and for a while it seemed as though France and Russia might come to an understanding. Carried away by the enthusiasm of Laharpe, who had returned to Russia from Paris, Alexander began openly to proclaim his admiration for French institutions and for the person of Bonaparte. Soon, however, came a change. Laharpe, after a new visit to Paris, presented to the tsar his *Reflexions on the*

¹Savary to Napoleon, Nov. 4, 1807. Tatischev, p. 226.

True Nature of the Consulship for Life, which, as Alexander said, tore the veil from his eyes, and revealed Bonaparte as "the most famous tyrant the world has produced." His disillusionment was completed by the murder of the duc d'Enghien, and diplomatic relations with Paris were broken off.

The tsar's attitude during the war that followed was pregnant with issues momentous for the world. In opposing Napoleon, "the oppressor of Europe and the disturber of the world's peace," Alexander already believed himself to be fulfilling a divine mission. In his instructions to Novosiltsov, his special envoy in London, he elaborated the motives of his policy in language which anticipated those exalted ideals of international policy which the Covenant of the League of Nations has now sought to realize. The outcome of the war, Alexander argued, was not to be only the liberation of France, but the universal triumph of "the sacred rights of humanity." To attain this it would be necessary "after having attached the nations to their government by making these incapable of acting save in the greatest interests of their subjects, to fix the relations of the states amongst each other on more precise rules, and such as it is to their interest to respect." A general treaty was to become the basis of the relations of the states forming "the European confederation," which would attain some of its results if, at the conclusion of the general war, it were possible to establish on clear principles the prescriptions of the rights of nations. "Why could not one submit to it," the tsar continued, "the positive rights of nations, assure the privilege of neutrality, insert the obligation of never beginning war until all the resources which the mediation of a third party could offer have been exhausted, having by this means brought to light the respective grievances, and tried to remove them? It is on such principles as these that one could proceed to a general pacification, and give birth to a league of which the stipulations would form, so to speak, a new code of the law of nations, which, sanctioned by the greater part of the nations of Europe, would without difficulty become the immutable rule of the cabinets, while those who should try to infringe it would risk bringing upon themselves the forces of the new union."¹ Meanwhile Napoleon never gave up hope of detaching him from the coalition. He had no sooner entered Vienna in triumph than he opened negotiations with him; he resumed them after Austerlitz. Russia and France, he urged, were "geographical allies"; there was between them no true conflict of interests; together they might rule the world. But Alexander was still determined "to persist in the system of disinterestedness in respect of all the states of Europe which he had thus far followed," and he again allied himself with Prussia. The campaign of Jena and the battle of Eylau followed; and Napoleon, though still intent on the Russian alliance, stirred up Poles, Turks and Persians to break the obstinacy of the tsar. A party too in Russia itself was clamorous for peace; but Alexander, after a vain attempt to form a new coalition, summoned the Russian nation to a holy war against Napoleon as the enemy of the Orthodox faith. The outcome was the rout of Friedland (June 13 and 14, 1807). Napoleon saw his chance and seized it. Instead of making heavy terms, he offered to the chastened autocrat his alliance, and a partnership in his glory.

The two emperors met at Tilsit on June 25. Alexander, dazzled by Napoleon's genius, was completely won. Napoleon knew well how to appeal to the imagination of his new-found friend. He would divide with Alexander the empire of the world; as a first step he would leave him in possession of the Danubian principalities and give him a free hand to deal with Finland; and, afterwards, the emperors of the East and West would drive the Turks from Europe and march across Asia to the conquest of India. A programme so stupendous awoke in Alexander's impressionable mind an ambition to which he had hitherto been a stranger. The interests of Europe were forgotten. "What is Europe?" he exclaimed to the French ambassador. "Where is it, if it is not you and we?"²

These new visions did not, however, blind Alexander to the obligations of friendship; and he refused to retain the Danubian

principalities as the price for suffering a further dismemberment of Prussia. It was not long before the first enthusiasm of Tilsit began to wane. Napoleon promised much, and performed little. The French remained in Prussia, the Russians on the Danube; each accused the other of breach of faith. Meanwhile, however, the personal relations of Alexander and Napoleon were cordial; and it was hoped that a fresh meeting might adjust all their differences. The meeting took place at Erfurt in Oct. 1808, and resulted in a treaty which defined a common policy. But Alexander's relations with Napoleon none the less changed. He realized that Napoleon had never intended his proposed "grand enterprise" seriously, and had only used it to preoccupy the mind of the tsar while he consolidated his own power in central Europe. From this moment the French alliance was for Alexander also an affair of pure policy. He used it, in the first instance, to remove "the geographical enemy" from the gates of St. Petersburg by wresting Finland from the Swedes (1809); and he hoped by means of it to make the Danube the southern frontier of Russia. Events were in fact rapidly tending to the rupture of the Franco-Russian alliance. Alexander, indeed, assisted Napoleon in the war of 1809, but he declared that he would not allow Austria to be crushed; and Napoleon complained bitterly of the inactivity of the Russian troops during the campaign. The tsar in his turn protested against Napoleon's encouragement of the Poles. In the matter of the French alliance he knew himself to be practically isolated in Russia, and he declared that he could not sacrifice the interest of his people and empire to his affection for Napoleon. The treaty of Vienna, which added largely to the grand-duchy of Warsaw, he complained had "ill requited him for his loyalty," and he was only mollified for the time by Napoleon's public declaration that he had no intention of restoring Poland.

But if Alexander suspected Napoleon, Napoleon was no less suspicious of Alexander; and, partly to test his sincerity, he sent an almost peremptory request for the hand of the grand-duchess Anne, the tsar's youngest sister. After some little delay Alexander returned a polite refusal. Napoleon's answer was to refuse to ratify the convention of Jan. 4, and to announce his engagement to the archduchess Marie Louise. From this time the relation between the two emperors became more and more strained. The annexation of Oldenburg, of which the duke was the tsar's uncle, to France in Dec. 1810, added another to the personal grievances of Alexander against Napoleon; while the ruinous reaction of the "continental system" on Russian trade made it impossible for the tsar to maintain a policy which was Napoleon's chief motive for the alliance. An acid correspondence followed, and ill-concealed armaments, which culminated in the summer of 1812 in Napoleon's invasion of Russia. Yet, even after the French had passed the frontier, Alexander still protested that his personal sentiments towards the emperor were unaltered. It was the occupation of Moscow and the desecration of the Kremlin, the sacred centre of Holy Russia, that changed his sentiment into passionate hatred. In vain the French emperor, within eight days of his entry into Moscow, wrote him a letter, revealing the desperate straits of the Grand Army, and appealed to "any remnant of his former sentiments."¹ Alexander returned no answer to these "fanfaronnades." "No more peace with Napoleon!" he cried, "He or I, or I or he: we cannot longer reign together!"

The campaign of 1812 was the turning-point of Alexander's life. Its horrors, for which he felt himself largely responsible, overset still more a mind never too well balanced. At the burning of Moscow, he declared afterwards, his own soul had found illumination, and he had received the divine revelation of his mission as the peacemaker of Europe. He tried to calm the unrest of his conscience by correspondence with the leaders of the evangelical revival, and sought for guidance in texts of scripture. It was not, however, according to his own account, till he met the Baroness de Krüdener (*q.v.*) at Basle, in the autumn of 1813, that his soul found peace. From this time a mystic pietism influenced his policy. Madame de Krüdener, and her colleague, the evangelist Empaytaz, became the confidants of his most secret thoughts; and during the campaign that ended in the occupation

of Paris the imperial prayer-meetings were the oracle on whose revelations hung the fate of the world.

Such was Alexander's mood when the downfall of Napoleon left him the most powerful sovereign in Europe. With the memory of Tilsit still fresh in men's minds, it was not unnatural that to cynical men of the world like Metternich he merely seemed to be disguising "under the language of evangelical abnegation" vast and perilous schemes of ambition. The puzzled powers were, in fact, the more inclined to be suspicious in view of other, and seemingly inconsistent, tendencies of the emperor, which yet seemed all to point to a like disquieting conclusion. For though Alexander had declared war against the revolution, Laharpe was once more at his elbow, and the catchwords of the gospel of humanity were still on his lips. The very proclamations which denounced Napoleon as "the genius of evil," denounced him in the name of "liberty," and of "enlightenment." A monstrous intrigue was suspected for the alliance of the eastern autocrat with the Jacobinism of all Europe, which would have issued in the substitution of an all-powerful Russia for an all-powerful France. At the congress of Vienna Alexander's attitude accentuated this distrust. Castlereagh, whose aim was the restoration of "a just equilibrium" in Europe, reproached the tsar to his face for a "conscience" which suffered him to imperil the concert of the powers by keeping his hold on Poland in violation of his treaty obligation.¹

Yet Alexander was sincere. Even the Holy Alliance, the pet offspring of his pietism, does not deserve the sinister reputation it has since obtained. To the other powers it seemed, at best "verbiage" and "exalted nonsense," at worst an effort of the tsar to establish the hegemony of Russia on the goodwill of the smaller signatory powers. To the Liberals, then and afterwards it was clearly a hypocritical conspiracy against freedom. Yet to Alexander himself it seemed the only means of placing the "confederation of Europe" on a firm basis of principle² and, so far from its being directed against liberty he declared roundly to all the signatory powers that "free constitutions were the logical outcome of its doctrines." Europe, in fact, owed much at this time to Alexander's exalted temper. During the period when his influence was supreme, the fateful years between the Moscow campaign and the close of the congress of Aix-la-Chapelle, it had been used largely in the interests of moderation and liberty. To him mainly it was due that France was saved from dismemberment, and received a constitution which, to use his own words, "united crown and representatives of the people in a sense of common interests."³ By this wise intervention Switzerland was saved from violent reaction. To his protection it was due that the weak beginnings of constitutional freedom in Germany were able for a while to defy the hatred of Austria. Lastly, whatever its ultimate outcome, the constitution of Poland was a genuine effort to respond to the appeal of the Poles for a national existence.

From the end of the year 1818 Alexander's views began to change. A revolutionary conspiracy among the officers of the guard, and a foolish plot to kidnap him on his way to the congress of Aix-la-Chapelle, are said to have shaken the foundations of his Liberalism. At Aix he came for the first time into intimate contact with Metternich, who was swift to take advantage of the psychological moment. From this time dates the ascendancy of Metternich over the mind of the Russian emperor and in the councils of Europe. It was, however, no case of sudden conversion. Though alarmed by the revolutionary agitation in Germany, which culminated in the murder of his agent, the dramatist Kotzebue (*q.v.*), Alexander approved of Castlereagh's protest against Metternich's policy of "the governments contracting an alliance against the peoples," as formulated in the Carlsbad decrees, 1819.⁴ He still declared his belief in "free institutions, though not in

such as are forced from feebleness, nor contracts ordered by popular leaders from their sovereigns." "Liberty," he maintained, "should be confined within just limits. And the limits of liberty are the principles of order."¹

It was the apparent triumph of the principles of disorder in the revolutions of Naples and Piedmont, combined with increasingly disquieting symptoms of discontent in France, Germany and among his own people, that completed Alexander's conversion. In the seclusion of the little town of Troppau, where in Oct. 1820 the powers met in conference, Metternich found an opportunity for cementing his influence over Alexander which had been wanting amid the turmoil and feminine intrigues of Vienna and Aix.² The issue was momentous. In January Alexander had still upheld the ideal of a free confederation of the European states, symbolized by the Holy Alliance; he had still protested against the claims of collective Europe to interfere in the internal concerns of the sovereign states. On Nov. 19 he signed the Troppau protocol, which consecrated the principle of intervention and wrecked the harmony of the concert (*see* TROPPAU, CONGRESS OF).

At Laibach, whither in the spring of 1821 the congress had been adjourned, Alexander first heard of the revolt of the Greeks. From this time until his death his mind was torn between his anxiety to realize his dream of a confederation of Europe and his traditional mission as leader of the Orthodox crusade against the Turks. At first, under the careful nursing of Metternich, the former motive prevailed. He struck the name of Alexander Ypsilanti from the Russian army list, and directed his foreign minister, Count Capo d'Istria, himself a Greek, to disavow all sympathy of Russia with his enterprise; and, next year, a deputation of the Greeks of the Morea on its way to the congress of Verona was turned back by his orders on the road. He made, indeed, some effort to reconcile the principles at conflict in his mind. He offered to surrender the claim that the affairs of the East were the "domestic concerns of Russia," and to march into Turkey, as Austria had marched into Naples, "as the mandatory of Europe."³ Metternich's opposition to this first opened his eyes to the true character of Austria's attitude towards his ideals. Once more in Russia, far from the fascination of Metternich's personality, the immemorial spirit of his people drew him back into itself; and when, in the autumn of 1825, he took his dying empress for change of air to the south of Russia, in order—as all Europe supposed—to place himself at the head of the great army concentrated near the Ottoman frontiers, his language was no longer that of "the peace-maker of Europe," but of the Orthodox tsar determined to take the interests of his people and of his religion "into his own hands." Before the momentous issue could be decided, however, Alexander died at Taganrog on Dec. 1 (Nov. 18, O.S.) 1825, "crushed," to use his own words, "beneath the terrible burden of a crown" which he had more than once declared his intention of resigning. A report, current at the time and often revived, affirmed that he did not in fact die. By some it was supposed that a mysterious hermit named Fomich, who lived at Tomsk until 1870 and was treated with peculiar deference by successive tsars, was none other than Alexander;⁴ but this legend is now discredited.⁵

Modern history knows no more tragic figure than that of Alexander. The brilliant promise of his early years; the haunting memory of the crime by which he had obtained the power to realize his ideals; and, in the end, the terrible legacy he left to Russia; a principle of government which, under lofty pretensions, veiled a tyranny supported by spies and secret police; an uncertain succession; an army permeated by organized disaffection; an armed Poland, whose hunger for liberty the tsar had whetted but not satisfied; the quarrel with Turkey, with its alternative of war or humiliation for Russia; an educational system rotten with official hypocrisy; a church in which conduct counted for nothing; orthodoxy and ceremonial observance for everything; economical

and financial conditions scarce recovering from the verge of ruin; and lastly, that curse of Russia—serfdom.

In private life Alexander displayed many lovable qualities. All authorities combine in praising his handsome presence and the charm of his address. His personal friendship, too, once bestowed, was never lightly withdrawn. By nature he was sociable and pleasure-loving, he proved himself a notable patron of the arts and he took a conspicuous part in all the gaieties of the congress of Vienna. In his later years, however, he fell into a mood of settled melancholy; and, though still accessible to all who chose to approach him with complaints or petitions, he withdrew from all but the most essential social functions, and lived a life of strenuous work and of Spartan simplicity. His gloom had been increased by domestic misfortune. He had been married, in 1793, without his wishes being consulted, to the beautiful and amiable Princess Maria Louisa of Baden (Elizabeth Feodorovna), a political match which proved the misfortune of both. The only child of the marriage, a little grandduchess, died on May 12, 1808; and their common sorrow drew husband and wife closer together. Towards the close of his life their reconciliation was completed by the wise charity of the empress in sympathizing deeply with him over the death of his beloved daughter by Madame Narishkine.

ALEXANDER II. (1818-1881), emperor of Russia, eldest son of Nicholas I., was born on April 29, 1818. Up to the moment of his accession in 1855 no one ever imagined that he would be known to posterity as a great reformer. In so far as he had any decided political convictions he seemed to be animated with the reactionary spirit of his time. The moral atmosphere of St. Petersburg (Leningrad) was very unfavourable to the development of any originality of thought or character. It was a time of government on martinet principles, under which all freedom of thought and all private initiative were suppressed vigorously by the administration. Alexander Nicolaevich received the education commonly given to young Russians of good family at that time—a smattering of a great many subjects and a good practical acquaintance with the chief modern European languages. His ordinary life was that of an officer of the Guards, modified by the ceremonial duties incumbent on him as heir to the throne. His natural kindness and indisposition for a military life had been fostered by his tutor Zhukovski, the amiable humanitarian poet, and they remained with him all through life. In 1841 he married the daughter of the grand duke Louis II. of Hesse, Maximilienne Wilhelmine Marie,

thenceforward known as Maria Alexandrovna, who bore him six sons and two daughters. He did not travel much abroad, for his father, in his desire to exclude from Holy Russia the subversive ideas current in Western Europe, disapproved of foreign tours and could not consistently encourage in his own family what he tried to prevent among the rest of his subjects. He visited England, however, in 1839, and in the years immediately preceding his accession he was entrusted with several missions to the courts of Berlin and Vienna. On March 2, 1855, during the Crimean War, he succeeded to the throne on the death of his father.

The first year of the new reign was devoted to the prosecution of the war and, after the fall of Sevastopol, to negotiations for peace. Then began a period of radical reforms, recommended by public opinion and carried out by the autocratic power. The rule of Nicholas, which had sacrificed all other interests to that of making Russia an irresistibly strong military power, had been tried by the Crimean War and found wanting. A new system had, therefore, to be adopted. All who had any pretensions to enlightenment declared loudly that the only way of restoring Russia to its proper position in Europe was to develop its natural resources and to reform thoroughly all branches of the administration. Fortunately for Russia the autocratic power was in the hands of a man who was impressionable enough to be deeply influenced by the spirit of the time, and who had sufficient prudence and practical common sense to prevent his being carried away by the prevailing excitement into the dangerous region of Utopian dreaming. At first he moved so slowly that many of the impatient, would-be reformers began to murmur. But important changes were made in the legislation concerning industry and commerce, and the new freedom thus accorded produced a large number of limited liability companies. At the same time plans were formed for constructing a great network of railways, partly for economic and partly for military purposes. Further progress was blocked by a great obstacle—the existence of serfage, and Alexander II. grappled boldly with the difficult and dangerous problem. Taking advantage of a petition presented by the Polish landed proprietors of the Lithuanian provinces, praying that their relations with the serfs might be regulated in a more satisfactory way, he authorized the formation of committees "for ameliorating the condition of the peasants" and laid down the principles on which the amelioration was to be effected. Without consulting his ordinary advisers, the tsar then ordered a copy of these instructions to be forwarded to the provincial governors of European Russia and suggested that perhaps the landed proprietors of other provinces might express a similar desire. In all provinces where serfage existed emancipation committees were formed. Emancipation involved very complicated problems affecting deeply the economic, social and political future of the nation. The main point at issue was whether the serfs should become agricultural labourers dependent economically and administratively on the landlords or be transformed into a class of independent communal proprietors. The emperor gave his support to the latter project, and the Russian peasantry accordingly acquired rights and privileges such as were enjoyed at that time by no other peasantry in Europe. In the numerous other questions submitted to him he began by consulting carefully the conflicting authorities, and while leaning as a rule rather to the side of those who were known as "Liberals" he never went so far as they desired and always sought some middle course by which conflicting interests might be reconciled. On March 3, 1861, the sixth anniversary of his accession, the emancipation law was signed and published. Other reforms followed in quick succession during the next five or six years: army and navy organization, a new judicial administration on the French model, a new penal code and a greatly simplified system of civil and criminal procedure, an elaborate scheme of local self-government for the rural districts and the large towns, with elective assemblies possessing a restricted right of taxation, and a new rural and municipal police under the direction of the minister of the interior. These new institutions were incomparably better than the old ones which they replaced, but they did not work such miracles as inexperienced enthusiasts expected. Comparisons were made, not with the past, but with an ideal state of things which never existed in Russia or elsewhere. Hence arose a general feeling of disappointment which acted on

different natures in different ways. Thus appeared in the educated classes two extreme groups: on the one hand, the discontented Conservatives, who recommended a return to a more severe disciplinarian régime; and on the other, the discontented Radicals, who would have been satisfied with nothing less than the adoption of a thoroughgoing socialistic programme. Between the two extremes stood the discontented Moderates, who indulged freely in grumbling without knowing how the unsatisfactory state of things was to be remedied. For some years the emperor, with his sound common sense and dislike of exaggeration, held the balance fairly between the two extremes; but when radicalism assumed more and more the form of secret societies and revolutionary agitation, he felt constrained to adopt severe repressive measures.

The revolutionary agitation was of a very peculiar kind. It was confined to a section of the educated classes and emanated from the universities and higher technical schools. At the beginning of the reform period there had been much enthusiasm for scientific as opposed to classical education. Russia required, it was said, not classical scholars, but practical scientific men capable of developing her natural resources. The government, in accordance with that view, had encouraged scientific studies until it discovered to its astonishment that there was some mysterious connection between natural science and revolutionary tendencies. Thus arose a struggle between the youthful, hot-headed partisans of revolutionary physical science and the zealous official guardians of political order—a struggle which has made the strange term Nihilism (*q.v.*) a familiar word not only in Russia but also in western Europe. The movement gradually assumed the form of terrorism and aimed at the assassination of prominent officials and even of the emperor himself, and the natural result was that the reactionary tendencies of the government were strengthened.

In foreign policy Alexander II. showed the same qualities of character as in internal affairs, ever trying prudently to steer a middle course. When he came to the throne the Crimean War was still going on, but he concluded peace with the allies as soon as he thought the national honour had been satisfied. Prince Gorchakov for fifteen years avoided foreign complications so that the internal strength of the country might be developed, while the national pride and ambition received a certain satisfaction by the expansion of Russian influence and domination in Asia. Twice, indeed, during that period the chancellor ran the risk of provoking war. The first occasion was in 1863, when the Western powers seemed inclined to interfere in the Polish question, and the Russian chancery declared categorically that no interference would be tolerated. The second occasion was during the Franco-German War of 1870–71, when the cabinet of St. Petersburg boldly declared that it considered itself no longer bound by the Black Sea clause of the Treaty of Paris. On both occasions hostilities were averted. Not so on the next occasion, when Russia abandoned her attitude of *recueillement*. When the Eastern question was raised in 1875 by the insurrection of Hercegovina, Alexander II. had no intention or wish to provoke a great European war. No doubt he was waiting for an opportunity of recovering the portion of Bessarabia which had been ceded by the treaty of Paris, and he perceived in the disturbed state of eastern Europe a possibility of obtaining the desired rectification of frontier, but he hoped to effect his purpose by diplomatic means in conjunction with Austria. At the same time he was anxious to obtain for the Christians of Turkey some amelioration of their condition, and to give thereby some satisfaction to his own subjects. As autocratic ruler of the nation which had long considered itself the defender of the Eastern Orthodox faith and the protector of the Slav nationalities, he could not remain inactive at such a crisis, and he gradually allowed himself to drift into a position from which he could not retreat without obtaining some tangible result. Supposing that the Porte would yield to diplomatic pressure and menace so far as to make some reasonable concessions, he delivered his famous Moscow speech, in which he declared that if Europe would not secure a better position for the oppressed Slavs he would act alone.

The diplomatic pressure failed and war became inevitable. During the campaign he displayed the same perseverance and the same moderation that he had shown in the emancipation of the serfs. To

those who began to despair of success, and advised him to conclude peace on almost any terms so as to avoid greater disasters, he turned a deaf ear; but when his more headstrong advisers urged him to insist on terms which would probably have produced a conflict with Great Britain and Austria, he resolved, after some hesitation, to make the requisite concessions. In this resolution he was influenced by the discovery that he could not rely on the expected support of Germany, and the discovery made him waver in his devotion to the German alliance, which had been the main pivot of his foreign policy; but his personal attachment to the emperor William prevented his adopting a hostile attitude towards the empire he had helped to create.

The patriotic excitement produced by the war did not weaken the revolutionary agitation. The struggle between the Terrorists and the police authorities became more and more intense, and attempts at assassination became more and more frequent. Alexander II. succumbed by degrees to the mental depression produced originally by the disappointments which he experienced in his home and foreign policy; and in 1880, when he had reigned twenty-five years, he entrusted to Count Loris-Melikov a large share of the executive power. In that year the empress died, and a few weeks afterwards he married secretly a Princess Dolgoruki, with whom he had entertained intimate relations for some years. Early in 1881, on the advice of Count Loris-Melikov, he determined to try the effect of some moderate liberal reforms on the revolutionary agitation, and for this purpose he caused a ukase to be prepared creating special commission, composed of high officials and private personages who should prepare reforms in various branches of the administration. On the very day on which this ukase was signed—March 13, 1881—he fell a victim to a Nihilist plot. When driving in one of the central streets of St. Petersburg, near the Winter Palace, he was mortally wounded by the explosion of some small bombs and died a few hours afterwards. (D. M. W.)

ALEXANDER III. (1845–1894), emperor of Russia, second son of Alexander II., was born on March 10, 1845. In natural disposition he bore little resemblance to his soft-hearted, liberal-minded father, and still less to his refined, philosophic, sentimental, chivalrous, yet cunning grand-uncle, Alexander I. He rather gloried in the idea of being of the same rough texture as the great majority of his subjects. His straightforward, abrupt manner savoured sometimes of gruffness, while his direct, unadorned method of expressing himself harmonized well with his rough-hewn, immobile features and somewhat sluggish movements. His education was not fitted to soften these peculiarities. During the first 20 years of his life he had no prospect of succeeding to the throne, because he had an elder brother, Nicholas, who seemed of a fairly robust constitution. Alexander received only the perfunctory and inadequate training of an ordinary grand duke of that period, which did not go much beyond primary and secondary instruction, practical acquaintance with French, English and German, and a certain amount of drill. When he became heir-apparent by the death of his elder brother in 1865, he began to study the principles of law and administration under Prof. Pobedonostsev, who influenced the character of his reign by instilling into his mind the belief that zeal for Eastern Orthodoxy ought, as an essential factor of Russian patriotism, to be specially cultivated by every right-minded tsar. His elder brother, when on his deathbed, had expressed a wish that his affianced bride, Princess Dagmar of Denmark (*see* MARIE FEODOROVNA), should marry his successor. The marriage was celebrated on Nov. 9, 1866. The union proved a most happy one to the end. During those years when he was heir-apparent—1865 to 1881—he allowed it to become known that he had certain ideas of his own which did not coincide with the principles of the existing Government.

He deprecated undue foreign influence in general and German influence in particular. He desired to see a homogeneous Russia—homogeneous in language, administration and religion. His father, though a good patriot according to his lights, had strong German sympathies, often used the German language in his private relations, occasionally ridiculed the exaggerations of the Slavophiles and based his foreign policy on the Prussian alliance. The antagonism first appeared publicly during the Franco-German War, when the tsar supported the cabinet of Berlin and the cesarevitch did not conceal his sympathies with the French. It reappeared in an intermittent fashion during the years 1875-79, on the Eastern question. At first the cesarevitch was more Slavophil than the Government, but any of the prevalent popular illusions he may have imbibed were soon dispelled by personal observation in Bulgaria, where he commanded the left wing of the invading army. He did not, however, make himself conspicuous in any way during the campaign, but fulfilled his military duties in a conscientious and unobtrusive manner. After many mistakes and disappointments the army reached Constantinople, and the Treaty of San Stefano was signed; but much that had been obtained by that important document had to be sacrificed at the Congress of Berlin. Prince Bismarck failed to do what was confidently expected of him. In return for the Russian support, which had enabled him to create the German empire, it was thought that he would help Russia to solve the Eastern question in accordance with her own interests, but to the surprise and indignation of the cabinet of St. Petersburg he confined himself to acting the part of "honest broker" at the congress, and shortly afterwards he ostentatiously contracted an alliance with Austria for the express purpose of counteracting Russian designs in eastern Europe. The cesarevitch drew the practical conclusion that for Russia the best thing to do was to recover as quickly as possible from her temporary exhaustion and to prepare for future contingencies by a radical scheme of military and naval reorganization. In accordance with this conviction he called his father's attention to the grave disorders and corruption in the army. His representations were not favourably received. Alexander II. had lost much of the reforming zeal which distinguished the first decade of his reign, and had no longer the energy required to undertake drastic reforms. On March 13, 1881, Alexander II. was assassinated by a band of Nihilists, and the autocratic power passed to the hands of his son.

In the last years of his reign, Alexander II. had been much exercised by the spread of Nihilist doctrines and the increasing number of anarchist conspiracies. On the very day of his death he signed a ukase, creating a number of consultative commissions which might have been easily transformed into an assembly of notables. Alexander III. at once cancelled the ukase before it was published, and in the manifesto announcing his accession to the throne he let it be very clearly understood that he had no intention of limiting or weakening the autocratic power which he had inherited from his ancestors. Nor did he afterwards show any inclination to change his mind. All the internal reforms which he initiated were intended to correct what he considered as the too liberal tendencies of the previous reign. In his opinion Russia was to be saved from anarchical disorders and revolutionary agitation, not by the parliamentary institutions and so-called liberalism of western Europe, but by the three principles which the elder generation of the Slavophiles systematically recommended—nationality, Eastern Orthodoxy and autocracy. His political ideal was a nation containing only one nationality, one language, one religion and one form of administration; and he did his utmost to prepare for the realization of this ideal by imposing the Russian language and Russian schools on his German, Polish and Finnish subjects, by fostering Eastern Orthodoxy at the expense of other confessions, by persecuting the Jews and by destroying the remnants of German, Polish and Swedish institutions in the outlying provinces. In the other provinces he sought to counteract what he considered the excessive liberalism of his father's reign. For this purpose he clipped the feeble wings of the zemstvo, an elective local administration resembling the county and parish councils in England, and placed the auton-

omous administration of the peasant communes under the supervision of landed proprietors appointed by the Government. At the same time he sought to strengthen and centralize the imperial administration, and to bring it more under his personal control. In foreign affairs he was emphatically a man of peace, but not at all a partisan of the doctrine of peace at any price. Though indignant at the conduct of Prince Bismarck towards Russia, he avoided an open rupture with Germany, and even revived for a time the Three Emperors' alliance. It was only in the last years of his reign, when M. Katkov had acquired a certain influence over him, that he adopted towards the cabinet of Berlin a more hostile attitude, and even then he confined himself to keeping a large quantity of troops near the German frontier, and establishing cordial relations with France. With regard to Bulgaria he exercised similar self-control. The efforts of Prince Alexander and afterwards of Stambolov to destroy Russian influence in the principality excited his indignation, but he persistently vetoed all proposals to intervene by force of arms. In central Asian affairs he followed the traditional policy of gradually extending Russian domination without provoking a conflict with Great Britain, and he never allowed the bellicose partisans of a forward policy to get out of hand. As a whole his reign cannot be regarded as one of the eventful periods of Russian history; but it must be admitted that under his hard, unsympathetic rule the country made considerable progress. He died at Livadia on Nov. 1, 1894, and was succeeded by his eldest son, Nicholas II.

ALEXANDER I., king of Epirus about 342 B.C., brother of Olympias the mother of Alexander the Great, and son-in-law of Philip of Macedon, whose daughter Cleopatra he married (336). In 332 he crossed over to Italy to assist the Tarentines against the Lucanians, Bruttians and Samnites. He gained considerable successes, and made an arrangement with the Romans for a joint attack upon the Samnites; but the Tarentines, suspecting him of the design of founding an independent kingdom, turned against him. Although the advantage at first rested with Alexander, he gradually lost it, and his supporters dwindled away. In 330 (or earlier) he was defeated at Pandosia, and slain by a Lucanian emigrant.

ALEXANDER (1893-1920), king of the Hellenes, second son of King Constantine and Queen Sophia, was born Aug. 1, 1893, and ascended the throne of Greece on the dethronement of his father, June 14, 1917. The Government itself was for the time in the hands of Venizelos, who had the confidence of the Allies; but the defeat of Germany, and Venizelos's diplomatic triumphs at the Peace Conference, seemed to breathe a new spirit into the young king. From the day of his triumphal entry into Adrianople, he took an active personal interest in the prospect of being the ruler of Greater Greece.

He died Oct. 25, 1920, by blood poisoning from the bite of a pet monkey. In Nov. 1919 King Alexander made amorganatic marriage with an Athenian lady, Aspasia Manos; and after his death a daughter was born to her in Paris on March 25, 1921. On Oct. 12, 1922, the marriage was declared valid by royal decree, so that Alexander's daughter became her father's legal heir, though she did not thereby acquire any rights in respect to the throne.

ALEXANDER III., known as THE GREAT (356-323 B.C.), king of Macedon, was the son of Philip II. of Macedon and Olympias, an Epirote princess. His father was pre-eminent for practical genius, his mother a woman of half-wild blood, weird, visionary and terrible; and Alexander himself is singular among men of action for the imaginative splendours which guided him.

and among romantic dreamers for the things he achieved. He was born in 356 B.C., probably about October (Hogarth, pp. 284 *seq.*). The court at which he grew up was the focus of great activities, for Philip, by war and diplomacy, was raising Macedonia to the headship of the Greek states, and the air was charged with great ideas. To unite the Greek race in a war against the Persian empire was set up as the ultimate mark for ambition, the theme of idealists. The great literary achievements of the Greeks in the 5th century lay already far enough behind to have become invested with a classical dignity; the meaning of Hellenic civilization had been made concrete in a way which might sustain enthusiasm for a body of ideal values, authoritative by tradition. And upon Alexander in his 14th year this sum of tradition was brought to bear through the person of the man who beyond all others had gathered it up into an organic whole: in 343-342 Aristotle (*q.v.*) came to Pella at Philip's bidding to direct the education of his son. We do not know what faculty the master-thinker may have had for captivating this ardent spirit; at any rate Alexander carried with him through life a passion for Homer, however, he may have been disposed to greyer philosophic theory. But his education was not all from books. The coming and going of envoys from many states, Greek and Oriental, taught him something of the actual conditions of the world. He was early schooled in war. At the age of 16 he commanded in Macedonia during Philip's absence and quelled a rising of the hill-tribes on the northern border; in the following year (338) he headed the charge which broke the Sacred Band at Chaeronea. Then came family dissensions such as usually vex the polygamous courts of the East. In 337 Philip repudiated Olympias for another wife, Cleopatra. Alexander went with his mother to her home in Epirus, and, though he soon returned and an outward reconciliation between father and son was contrived, their hearts were estranged. The king's new wife was with child; her kinsmen were in the ascendant; the succession of Alexander was imperilled. Some negotiations which Pixodarus, the satrap of Caria, opened with the Macedonian court with a view to effecting a marriage alliance between his house and Philip's, brought Alexander into fresh broils. In 336 Philip was suddenly assassinated whilst celebrating at Aegae the marriage of his daughter to Alexander I. of Epirus in the presence of a great concourse from all the Greek world. It is certain that the hand of the assassin was prompted by someone in the background; suspicion could not fail to fall upon Alexander among others. But guilt of that sort would hardly be consistent with his character as it appears in those early days.

Accession.—Alexander was not the only claimant to the vacant throne, but, recognized by the army, he soon swept all rivals from his path. The newly born son of Philip by Cleopatra, and Alexander's cousin Amyntas, were put to death, and Alexander took up the interrupted work of his father. That work was on the point of opening its most brilliant chapter by an invasion of the great king's dominions; the army was concentrated and certain forces had already been sent on to occupy the opposite shore of the Hellespont. The assassination of Philip delayed the blow, for it immediately made the base, Macedonia, insecure, and in such an enterprise, plunging into the vast territories of the Persian empire, a secure base was everything. Philip's removal had made all the hill-peoples of the north and west raise their heads and set the Greek states free from their fears. A demonstration in Greece, led by the new king of Macedonia, momentarily checked the agitation, and at the diet at Corinth Alexander was recognized as captain-general (*ἡγεμὼν αὐτοκράτωρ*) of the Hellenes against the barbarians, in the place of his father Philip. In the spring of 335 he went out from Macedonia northwards, struck across the Balkans, by the Kojia or Shipka pass, frustrating the mountain warfare of its tribes by a precision of discipline which, probably, no other army of the time could have approached, and traversed the land of the Triballians (Rumelia) to the Danube. To gratify his own imagination or strike the imagination of the world he took his army over the Danube and burnt a settlement of the Getae upon the other side. Meanwhile the Illyrians had seized Pelion (Pliassa), which commanded the passes on the west of Macedonia, and from the Danube. Alexander marched straight

thither over the hills. He had hardly restored Macedonian prestige in this quarter when he heard that Greece was aflame. Thebes had taken up arms. By a forced march he took the Thebans completely by surprise, and in a few days the city, which a generation before had won the headship of Greece, was taken. There were to be no half-measures now; the city was wiped out of existence with the exception of its temples and the house which had been Pindar's. Greece might now be trusted to lie quiet for some time to come. The Panhellenic alliance (from which Sparta still stood aloof) against the barbarians was renewed. Athens, although known to be hostile at heart to the Macedonian power, Alexander treated all through with eager courtesy.

Invasion of Asia Minor.—In the spring of 334, Alexander crossed with an army of between 30,000 and 40,000 men, Macedonians, Illyrians, Thracians and the contingents of the Greek states, into Asia. The place of concentration was Arisbe on the Hellespont. Alexander himself first visited the site of Troy and there went through those dramatic acts of sacrifice to the Ilian Athena, assumption of the shield believed to be that of Achilles and offerings to the great Homeric dead, which are significant of the poetic glamour shed, in the young king's mind, over the whole enterprise, and which men will estimate differently according to the part they assign to imagination in human affairs. To meet the invader the great king had in Asia Minor an army certainly not much larger than Alexander's, if as large, gathered under the satraps of the western provinces at Zeleia. He had also, what was more serious, command of the Aegean. Alexander could communicate with his base only by the narrow line of the Hellespont, and ran the risk, if he went far from it, of being cut off altogether. To draw him after them, while avoiding a conflict, was sound strategy for the Persian generals. It was urged upon them by their colleague the Rhodian Memnon.

Granicus.—Strategic considerations were cancelled by the Persian barons' code of chivalry, and Alexander found them waiting for him on the banks of the Granicus. It was a cavalry mêlée, in which the common code of honour caused Macedonian and Persian chieftains to engage hand to hand, and at the end of the day the relics of the Persian army were in flight, leaving the high-roads of Asia Minor clear for the invader. Alexander could now accomplish the first part of the task belonging to him as captain-general to the Hellenes, that liberation of the Greek cities of Asia Minor, for which Panhellenic enthusiasts had cried out so long. He went to take possession of the old Lydian capital Sardis, the headquarters of the Persian government on this side of the Taurus, and the strong city surrendered without a blow. And now in all the Greek cities of Aeolis and Ionia the oligarchies or tyrants friendly to Persia fell, and democracies were established under the eye of Alexander's officers. Only where the cities were held by garrisons in the Persian service, garrisons composed mainly of Greek mercenaries, was the liberator likely to meet with any resistance. From Ephesus indeed the garrison fled upon the news of Granicus, but Miletus required a siege. The Persian fleet in vain endeavoured to relieve it, and Miletus did not long hold out against Alexander's attack. It was at Halicarnassus that Alexander first encountered the stubborn resistance, at Halicarnassus where Memnon and the satraps of Caria had rallied what land-forces yet belonged to Persia in the west. When winter fell, Alexander had captured the city itself, but the two citadels still held out against his blockade.

Meanwhile Alexander was making it plain that he had come not merely as captain-general for a war of reprisals, but to take the Persian's place as king of the land. The conquered provinces were organized under Macedonian governors and in Caria a dethroned princess of the native dynasty, Ada, was restored to power. In the winter, whilst Parmenio advanced upon the central plateau to make the occupation of Phrygia effective, Alexander himself passed along the coast to receive the submission of the Lycians and the adherence of the Greek cities of the Pamphylian sea-board. The hills inland were the domain of fighting tribes which the Persian government had never been able to subdue. To conquer them, indeed, Alexander had no time, but he stormed some of their fortresses to hold them in check, and marched

through their territory when he turned north from Pamphylia into the interior. The point of concentration for the following year's campaign had been fixed at Gordium, a meeting-place of roads in Northern Phrygia. The story of Alexander's cutting the fatal "Gordian knot" on the chariot of the ancient Phrygian king Gordius is connected with his stay in this place.

Extension of Alexander's Power.—Whilst Alexander had been grounding his power in Asia Minor, he had run a narrow risk of losing his base in Europe. He had after the siege of Miletus disbanded the Graeco-Macedonian fleet, surrendering for the time all attempts to challenge the command of the Aegean. Memnon the Rhodian, now in supreme command of the Persian fleet, saw the opportunity to detach the Greek island-states where discontent always smouldered in Alexander's rear. But Memnon died at the critical moment whilst laying siege to Mytilene and the great plan collapsed. A Persian fleet still held the sea, but it effected little, and presently fresh Graeco-Macedonian squadrons began to hold it in check. It was, however, the need to ensure command of the sea and free all lines of communication behind him that determined Alexander's plan for the next campaign. If he mastered the whole coast-line of the Levant, the enemy's fleet would find itself left in the air. The Syrian coast was accordingly his immediate objective when he broke up from Gordium for the campaign of 333. He was through the Cilician Gates before the Persian king, Darius III., had sent up a force adequate to hold them. His passage through Cilicia was marked by a violent fever that arrested him for a while in Tarsus, and meantime a Persian army was waiting for him in northern Syria under the command of Darius himself. In the knot of mountains which close in about the head of the Gulf of Alexandretta, Alexander, following hard by the coast, marched past the Persian army whilst it was crossing the Amanus chain more to the East.

Battle of Issus.—To cut Alexander's communications with the rear, Darius now committed the error of entangling his large force in the mountain defiles. Alexander turned, and near the town of Issus fought his second pitched battle, sending Darius and the relic of his army in wild flight back to the East.¹ It was an incident which did not modify Alexander's plan. He did not press the pursuit far, although the great king's camp with his harem fell into his hands. The chivalrous courtesy which he showed to the captive princesses was a favourite theme for later rhetoricians. He went on his way to occupy Syria and Phoenicia. It is now that we get definite evidence as to the scope of Alexander's designs; for Darius opened negotiations in which he ultimately went so far as to offer a partition of the empire, all west of the Euphrates, to be Alexander's. Alexander refused the bargain and definitely claimed the whole.² The conquest of the Phoenician coast was not to be altogether easy, for Tyre shut its gates and for seven months Alexander had to sit before it—one of those obstinate sieges which mark the history of the Semitic races. When it fell, Alexander had the old Tyrian people scattered to the winds, sold as slaves. Gaza offered a resistance equally heroic, lasting two months, and here too the old population was dispersed. The occupation of the rest of Syria and Palestine proceeded smoothly, and after the fall of Gaza Alexander's way lay open into Egypt.³ Egypt was the last of the Mediterranean provinces to be won, and here no defence was made. To the native Egyptians Alexander appeared as a deliverer from the Persian tyranny, and he sacrificed piously to the gods of Memphis. The winter (332–331) which Alexander spent in Egypt saw two memorable actions on his part. One was the expedition (problematic in its motive and details) to the oracle of Zeus Ammon (Oasis of Siwa), where Alexander was hailed by the priest as son of the god, a belief which the circle of Alexander, and perhaps Alexander himself, seem hereafter to have liked to play

with in that sort of semi-serious vein which still allowed him in the moments of every-day commonplace to be the son of Philip. The other action was the foundation of Alexandria at the Canopic mouth of the Nile, the place destined to be a new commercial centre for the eastern Mediterranean world which Alexander had now taken in possession, to rise to an importance which the founder, although obviously acting with intention, can hardly have foreseen. (E. Keller, *Alex. d. Grosse nach der Schlacht bei Issus*, 1904).

Invasion of Persia.—In the spring of 331 Alexander could at last leave the Mediterranean to strike into the heart of the

AFTER G. CURTIUS RUFUS, "ALEXANDRI MAGNI VITA," 1696

ALEXANDER DEFEATING DARIUS III. KING OF PERSIA IN 331 B.C.

The battle of Arbela (more properly Gaugamela) resulted in the destruction of the last army of Persia. After the victory there was no further organized resistance, and Alexander seized Susa and Babylon

Persian empire, for by his occupation of the coasts the Persian command of the sea had inevitably collapsed. Returning through Syria, and stopping at Tyre to make final arrangements for the conquered provinces, he traversed Mesopotamia and struck the Tigris some four marches above the site of Nineveh. It was near Nineveh that Darius was waiting with an army, stronger in cavalry than in infantry, mustered from all parts of the empire. The happy coincidence of a lunar eclipse gives us Sept. 20, 331, as the exact day upon which the Macedonian army crossed the Tigris.

Battle of Arbela.—Alexander came within sight of the Persian host without having met with any opposition since he quitted Tyre. He had now to settle the most serious problem which had yet faced him, for in the plains the Persian army was formidable by sheer bulk. But the day showed the Macedonian army equal to the task. The last army gathered by an Achaemenian king was shattered in the battle called popularly after the city of Arbela some 60m. distant, or more precisely after the village of Gaugamela hard by. Darius fled eastwards into Media and again Alexander waited till he had secured the provinces to the south. He followed the Tigris into Babylonia, the central seat of the empire and its richest region, and from Babylon went on to seize the fabulous riches which the Persian kings had amassed in their spring residence, Susa. Thence he at last ascended upon the Iranian plateau. The mountain tribes on the road (the Uxii, Persian *Huzha*), accustomed to exact blackmail even from the king's train, learnt by a bitter lesson that a stronger hand had come to wield the empire. Alexander entered Persis, the cradle of the Achaemenian house, and came upon fresh masses of treasure in the royal city, Persepolis. He destroyed the royal palace by fire, an act which has been variously estimated by historians. Ostensibly a solemn revenge for the burning of Greek temples by

³The story of Alexander's visit to Jerusalem rests on no better authority than a later Jewish romance.

Xerxes, it has been justified as a symbolical act calculated to impress usefully the imagination of the East, and condemned as a senseless and vainglorious work of destruction.

With the spring of 330 Alexander was prepared for further pursuit. Darius fled northwards from Ecbatana upon his approach. At Ecbatana new masses of treasure were seized, but when once the necessary measures which its disposal and the

THE DEATH OF ALEXANDER THE GREAT AT BABYLON IN 323 B.C.
Alexander's death, in his 33rd year, put an end to the Macedonian subjugation of the East and left his empire a prey to his ambitious generals.
From an 18th century Persian ms. in the Metropolitan Museum of Art

occupation of the Median capital entailed were taken, Alexander continued the pursuit. It was an exciting chase of king by king, in which each covered the ground by incredible exertions, shedding their slower-going followers as they went, past Rhagae (Rai) and the Caspian gates, till early one morning Alexander came in sight of the broken train which still clung to the fallen king. He had become a puppet in the hands of his cousin Bessus and the Persian magnates with him (see DARIUS III.), and at this extremity they stabbed him and allowed Alexander to become master only of his corpse (summer 330).

The pursuit had brought Alexander into that region of mountains to the south of the Caspian which connects western Iran with the provinces to the east of the great central desert. To conquer this remaining portion of the empire, Alexander now went on through the mountain belt, teaching the power of his arms to the hillsmen, Tapyri and Mardi, till he came, passing through Zadracarta (Asterabad), to Parthia and thence to Aria. In these farther provinces of Iran the Macedonian invader had for the first time to encounter a serious national opposition, for in the west the Iranian rule had been merely the supremacy of an alien power over native populations indifferent or hostile. Here the ruling race was at home. In Asia, Alexander learnt that Bessus had taken the diadem as Darius's successor in Bactria, but so soon as he marched against him Aria rose in his rear, and Alexander had to return in haste to subdue the revolt. Nor did he, when this was accomplished, again strike directly at Bactria, but made a wide turning movement through Seistan over Kandahar into the Kabul valley. It was on the way, in Seistan at Prophthasia (mod. *Farrah?*), that the alienation between Alexander and his Macedonian followers, which becomes sensible in the latter part of his career, first showed itself in an ugly form. Alexander had come to merge the characters of Macedonian king and Hellenic captain-general, with which he had set out, in that of Oriental despot (Spieker, *Hof u. Hofordnung Al. d. Gr.*, 1904).

He wore on occasions of state the Persian dress. (According to pseudo-Plutarch, *de fort. Al. i. 8*, it was the simpler *Persian* dress, not the Median.) A discontent began to work among the Macedonians, and at Prophthasia the commander of the Macedonian cavalry, Philotas, the son of Parmenio, and certain others were arraigned before the army on the charge of conspiring against the king's life. They were condemned and put to death. Not satisfied with procuring this, Alexander had Parmenio himself, who had been left in command in Media, put to death by secret orders. It is perhaps the worst crime, because the most cold-blooded and ungenerous, which can be laid to his charge. By the winter of 329-328 Alexander had reached the Kabul valley at the foot of the Paropamisadae (Hindu Kush).

The ordinarily received chronology makes Alexander reach the Kabul valley in the winter of 330-329. That to fit the actions and distances covered by Alexander into such a scheme, assuming that he went by Seistan and Kandahar, would involve physical impossibilities has been pointed out by Count Yorck v. Wartenburg and D. G. Hogarth.

Northern India.—In the spring of 328 Alexander crossed the Hindu Kush into Bactria and followed the retreat of Bessus across the Oxus and into Sogdiana (Bokhara). Here Bessus was at last caught and treated with the barbaric cruelty which the rule of the old Persian monarchy prescribed for rebels. Till the spring of 327 Alexander was moving to and fro in Bactria and Sogdiana, beating down the recurrent rebellions and planting Greek cities. Just as in 335 he had crossed the Danube, so he now made one raid across the frontier river, the Jaxartes (Sir Daria), to teach the fear of his name to the outlying peoples of the steppe (summer 328). And meanwhile the rift between Alexander and his European followers continued to show itself in dark incidents—the murder of Clitus at Maracanda (Samarkand), when Alexander struck down an old friend, both being hot with wine; the claim that Alexander should be approached with prostration (*proskynesis*), opposed somewhat strangely by the philosopher Callisthenes, Aristotle's nephew, who had come in the king's train and embroidered his history of the campaign with gross flatteries; the conspiracy of the pages in Bactria, which was made an occasion for putting Callisthenes to death. It was now that Alexander completed the conquest of the provinces north of the Hindu Kush by the reduction of the last mountain strongholds of the native princes. In one of them he captured Roxana, the daughter of Oxyartes, whom he made his wife. Before the summer of 327 he had once more crossed the Hindu Kush on his way to India (for the campaigns in the north-east see F. von Schwarz, *Alex. d. Grossen Feldzüge in Turkestan*, v. 1893).

Whilst the heavier troops moved down the Kabul valley to Peucelaotis (Chârsadda) under Perdikkas and Hephaestion, Alexander with a body of lighter-armed troops and cavalry pushed up the valleys which join the Kabul from the north—through the regions now known as Bajour, Swat and Buner, inhabited by Indian hill peoples, as fierce then against the western intruder as their Pathan successors are against the British columns. The books give a number of their "cities" reduced by Alexander—walled mountain villages which can in some cases be identified more or less certainly with places where the clans are established to-day. The crowning exploit was the reduction of Aornus,¹ a stronghold perched on a precipitous summit above the Indus, which it was said that Heracles had failed to take. How much of the story of Alexander's discovery of the sacred mountain of the Nysa and the traces of Dionysus is due to the invention of Aristobulus and Clitarchus (Arrian did not find it in Ptolemy) we cannot say. Meantime Perdikkas and Hephaestion had built a bridge over the Indus, and by this in the spring of 326 Alexander passed into the Punjab (at Ohind, 16m. above Attock, according to Foucher, *Notes sur la géogr. anc. du Gandhâra*, 1902). The country into which he came was dominated by three principalities, that of Ambhi (Gr. *Omphis*, Curt. viii. 12. 6) between the Indus and the Hydaspes (*Jhelum*, *Jehlum*), centred in the great city of Takasila (Gr. *Taxila*), that of the Paurava rajah (Gr. *Porus*) be-

¹Sir Aurel Stein believes that he has discovered Aornus; see *Geographical Journal*, vol. 70, No. 6, pp. 515-540, 1927.

tween the Hydaspes and Acesines (*Chenab*), and that of Abhisara (Gr. *Abisares*) between the same two rivers higher up, on the confines of Kashmir (Stein, *Rajatarangini*, transl. bk. i. 180, v. 217). The king of Taxila and Porus were at enmity, and for this cause the invader could reckon upon Omphis as a firm ally. Porus was prepared to contest the passage of the Hydaspes with all his strength. Abisares preferred to play a double game and wait upon events. Alexander reached the Hydaspes shortly before the rains broke, when the river was already swollen. Porus held the opposite bank with a powerful army, including 200 elephants. Alexander succeeded in taking a part of his forces across the river higher up during a night of torrential rain, and then he fought the fourth and last of his pitched battles in Asia, the one which put to proof more shrewdly than any of the others the quality of the Macedonian army as an instrument of war, and yet again emerged victorious. Porus fell sorely wounded into his hands.¹ Porus had saved his honour, and now Alexander tried, and not in vain, to gain him as a friend. When he continued his progress eastwards across the Acesines, Porus was an active ally. Alexander moved along close under the hills. After crossing the Hydraōtes (Rāvi) he once more came into contact with hostile tribes, and the work of storming petty towns began again. Then the Hyphasis (Beas) was reached, and here the Macedonian army refused to go any farther. It was a bitter mortification to Alexander, who probably believed that he had not much farther to go to reach the ocean and the eastern limit of the inhabited world. For three days the will of king and people were locked in antagonism; then Alexander gave way; the long eastward movement was ended; the return began.

The Return.—Alexander left the conquered portion of India east of the Indus to be governed under Porus, Omphis of Taxila, and Abisares, the country west of the Indus under Macedonian governors, and set out to explore the great river to its mouth (for the organization of the Indian provinces, see especially Niese, vol. i., pp. 500). The fleet prepared on the Hydaspes sailed in Nov. 326, while a land army moved along the bank. The confluence of the Hydaspes and Acesines passed, the Macedonians were once more in a region of hostile tribes with towns to be stormed. It was at one of these, a town of the Malli, that a memorable incident occurred, such as characterized the personality of Alexander for all succeeding time. He leapt from the wall with only three companions into the hostile town, and, before the army behind him could effect an entrance, lay wounded almost to death.² He recovered and beat down the resistance of the tribes, leaving them annexed to the Macedonian satrapy west of the Indus. Below the confluence of the Punjab rivers into the single stream of the Indus the territory of loose tribes was succeeded by another group of regular principalities, under the rajahs called by the Greeks Musicanus, Oxycanus and Sambus. These opposed a national resistance to the Macedonians, the fires of which were fanned by the Brahmins, but still the strong arm of the western people prevailed. The rajah of Patala at the apex of the Indus delta abandoned his country and fled. It was the high summer of 325 when Alexander reached Patala. From there he explored both arms of the delta to the ocean, now seen by the Macedonians for the first time. He had determined that the Indus fleet should be used to explore this new world and try to find a waterway between the Indus and the Persian Gulf. A great part of the land-forces had been already sent off under Craterus in the earlier summer to return west by Kandahar and Seistan; the fleet was to sail under the Greek Nearchus from the Indus mouth with the winter monsoon; Alexander himself with the rest of the land-forces set out in Sept. 325, to go by the coast of Baluchistan, through the appalling sand-wastes of the Mekran.³

¹Beside V. Smith (cited below) see Schubert, "Die Porusschlacht," in *Rhein. Mus.* lvi., 1901, p. 543.

²There seems nothing to fix the exact spot of this town; the common identification with Multan is, according to Raverty and V. Smith, certainly wrong.

³For the Indian campaigns of Alexander see especially McCrindle, *Invasion of India by Alexander the Great* (1896); Vincent A. Smith, *Early History of India* (1904), and the references there given to the researches of Sir T. H. Holdich, Raverty and Foucher; A. Anspach, *De Alex. Magni exped. ind.* (1903).

He would seem to have kept down to the coast until the headland of Ras Malan was reached, scattering before him the bands of Arabitae and Oritae who were the inhabitants of this well-provisioned tract. For the 150 miles between Ras Malan and Pasni, Alexander was compelled by the natural barriers to march inland, and it was here that his troops sank under the horrors of heat and thirst and sand. The coast once regained, the way was easy; no such desert had to be traversed, when Alexander again struck inland for the chief city of the Gedrosians (Pura), and thence made his way into Carmania. Here the spent troops rested; here the army of Craterus joined them, and Nearchus came to announce his safe arrival at the entrance of the Persian gulf.¹

The machine of empire had not functioned altogether smoothly while the king had been absent, and on Alexander's reappearance many incapables and rogues in high office had to be replaced by better men. In Carmania, in Persis, complaints from the provinces continued to reach him, as well as the news of disorders in Macedonia and Greece. New orders and appointments served to bring the empire into hand again, and at Susa in the spring of 324 Alexander rested, the task of conquering and compassing the Achaemenian realm achieved. The task of its internal reorganization now began to occupy him—changes, for instance, in the military system which tended to assimilate Macedonians and Orientals. The same policy of fusion was furthered by the great marriage festival at Susa, when Alexander took two more wives from the Persian royal house, married a number of his generals to Oriental princesses, and even induced as many as he could of the rank-and-file to take Asiatic wives. This policy did not allay the discontent of the Macedonian army, and when Alexander in the summer of 324 moved to the cooler region of Media, an actual mutiny of the Macedonians broke out on the way at Opis on the Tigris. It was occasioned by the discharge of the Macedonian veterans, and only the personal magnetism of Alexander and his threat to entrust himself altogether to the Orientals availed to quell it. At Ecbatana the death of Hephaestion for a time plunged Alexander into a passion of mourning. But by the winter (324-323) he was again active, bringing the hill-tribes on the south-west border of Media, the Cossaei, into subjection. In the spring of 323 he moved down to Babylon, receiving on the way embassies from lands as far as the confines of the known world, for the eyes of all nations were now turned with fear or wonder to the figure which had appeared with so superhuman an effect upon the world's stage. The embassy from Rome, however, is almost certainly a later, and an inevitable, invention. The exploration of the waterways round about the empire was Alexander's immediate concern, the discovery of the presumed connection of the Caspian with the Northern Ocean, the opening of a maritime route from Babylon to Egypt round Arabia. The latter enterprise Alexander designed to conduct in person; under his supervision was prepared in Babylon an immense fleet, a great basin dug out to contain 1,000 ships, and the water-communications of Babylonia taken in hand. Innovations were carried out in the tactical system of the army which were to modify considerably the methods of future battle-fields. At last all was ready; the 20th of the month Daesius (? June 5) was fixed for the king's setting forth. On the 15th and 16th Alexander caroused deep into the night at the house of the favourite Medius. On the 17th he developed fever; for a time he treated it as a momentary impediment to the expedition; but on the 27th his speech was gone, and the Macedonian army was suffered to pass, man by man, through his chamber to bid him farewell. On the 28th (June 13) Alexander died.²

His son by Roxana, the so-called ALEXANDER "AEGUS," was born a few months later. He and his uncle Philip, as joint kings, were placed under the guardianship of Perdikkas, Peithon and Antipater in succession. After the death of Antipater (319) Roxana fled with him to Epirus, and was afterwards taken back to Mace-

¹Tomaschek, "Topographische Erläuterung der Küstenfahrt Nearchs" in the *Sitzungsberichte der kaiserl. Akad. d. Wissensch.* of Vienna (*Philosoph.-histor. Klasse*, vol. cxxi.); Major P. M. Sykes, *Ten Thousand Miles in Persia* (1902), pp. 166 *et seq.*

donia, together with Olympias, by Polyperchon. All three fell into the hands of Cassander; Alexander and his mother were put to death in 310–309 by order of Cassander (*Justin* xiv. 6, xv. 2). The meaningless surname of *Aegus*, still given in some books to this Alexander, is perhaps derived from a modern misreading of the text of the Astronomical Canon, ΑΙΓΟΤ for ΑΛΛΟΤ.

Character and Policy.—Alexander the Great is one of the instances of the vanity of appealing from contemporary disputes to “the verdict of posterity”; his character and his policy are estimated to-day as variously as ever. Certain features—the high physical courage, the impulsive energy, the fervid imagination—stand out clear; beyond that disagreement begins. That he was a great master of war is admitted by most of those who judge his character unfavourably, but even this has been seriously questioned (e.g., by Beloch, *Griech. Gesch.* iii. [i.], p. 66). There is a dispute as to his real designs. That he aimed at conquering the whole world and demanded to be worshipped as a god is the traditional view. Droysen denies the former, and Niese maintains that his ambition was limited by the bounds of the Persian empire and that the claim to divine honours is fabulous (*Historische Zeitschr.* lxxix., 1897, 1 f.). It is true that our best authority, Arrian, fails to substantiate the traditional view satisfactorily; on the other hand those who maintain it urge that Arrian's interests were mainly military, and that the other authorities, if inferior in trustworthiness, are more complete in range of vision. Of those, again, who maintain the traditional view, some, like Niebuhr and Grote, regard it as convicting Alexander of mad ambition and vainglory; whilst to Kaerst, Alexander only incorporates ideas which were the timely fruit of a long historical development. The policy of fusing Greeks and Orientals again is diversely judged. To Droysen and Kaerst it accords with the historical conditions; to W. W. Tarn, whose chapters in the *Cambridge Modern History*, vol. vi., give an able survey of Alexander's career in the light of the most recent studies, it was one of Alexander's great contributions to history; to Grote and to Beloch it is a betrayal of the prerogative of Hellenism.

Some notion of the personal appearance of Alexander may be got from the literature and the surviving monuments. He is described as of an athletic frame, though not taller than the common, and a white and ruddy complexion. The expression of his eyes had something “liquid and melting” (τῶν ὀμμάτων τὴν διάχυσιν καὶ ὑγρότητα) and the hair which stood up over his forehead gave the suggestion of a lion. He had a way of carrying his head somewhat aslant. (See especially Plut. *Alex.* 4; *de Alex. fort.* ii. 2.) The greatest masters of the time executed portraits of him, Lysippus in sculpture, Apelles in painting and Pyrgoteles in graven gems. Among surviving monuments, we have no completely certified portraits except the Tivoli herm (now in the Louvre) and the coins struck by his successors. The herm is a dry work and the head upon the coins shows various degrees of idealization. There are, however, a considerable number of works which can make out a better or worse claim either to be portraits of Alexander or to reproduce his type, and a large field of discussion is therefore open as to their values and classification (F. Kopp, *Über das Bildnis Alexanders d. Grossen* (1892); K. J. Ujfalvy, *Le Type physique d'Alexandre le Grand* (1902); T. Schreiber, *Studien über das Bildnis Alexanders d. Grossen* (1903); J. J. Bernoulli, *Die erhaltenen Darstellungen Alexanders d. Grossen* (1905). Alexander shaved clean, and set the fashion in this respect for the Graeco-Roman world for the next 500 years.

The campaigns and life of Alexander did not lack contemporary historians, some of them eye-witnesses and even associates. They included the philosopher Callisthenes, put to death by Alexander in 327, whose history went up to the death of Darius, Alexander's general Ptolemy, afterwards king in Egypt; Nearchus, who commanded the fleet that sailed from the Indus to the Persian Gulf; Onesicritus, who served as pilot in the same fleet, and Aristobulus who was with Alexander in India. Clitarchus, whose highly coloured version of the life of Alexander became the popular authority for succeeding generations, is now believed to have written in the 3rd century A.D. Besides the historical narrative, there were works mainly geographical or topographical left by persons like Baeton and Diognetus, whom Alexander had employed (as *ἡγεμῶνας*) to survey the roads over which he passed. All such original sources have now perished. The fragments are collected in the Didot edition of Arrian by Karl Müller. Not reckoning

scattered notices, we depend principally upon five later compositions, Diodorus, book xvii. (c. 20 B.C.), the work of Quintus Curtius (c. A.D. 42), Plutarch's (c. A.D. 45–125) *Life of Alexander*, Arrian's *Anabasis and Indica* (c. A.D. 150), and the relevant books of Justin's abridgement (2nd cent. A.D.) of the history of Trogus (c. 10 B.C.). To these we may add the Latin *Itinerarium Alexandri*, a skeleton outline of Alexander's campaigns dedicated to the Emperor Constantius (A.D. 324–361), printed at the end of the Didot edition of Arrian, and the *Epitome Rerum Gestarum Alexandri magni*, an abridgement made in the 4th or 5th century of a lost Latin work of uncertain date, combining history with elements taken from the *Romance* (edited by O. Wagner, Leipzig, 1900). The relation of these works to the various original sources constitutes the critical problem before the modern historian in reference to the history of Alexander. A bibliography of modern literature bearing on Alexander will be found connected with Mr. W. W. Tarn's chapters in the *Cambridge Ancient History*, vol. vi. (E. R. B.)

THE ROMANCE OF ALEXANDER

The figure of Alexander naturally impressed itself upon the imagination of the world which his career had shaken. The romance of Alexander is found written in the languages of nearly all peoples from the Indian Ocean to the Atlantic, but all these versions are derived, mediately or immediately, from the Greek original which circulated under the false name of Callisthenes. The Greek pseudo-Callisthenes (otherwise *Aisopos*) we possess in three recensions, based all upon a book produced in Egypt in the 2nd century A.D. But this book itself was a farrago of heterogeneous elements—pieces of genuine history, ancient stories once told in Babylon of Gilgamesh or Etanna; literary forgeries of the days soon after Alexander, like the oldest part of the “Testament of Alexander,” and variations according to the bent of different times and peoples. In the Persian version Alexander (Iskander) became a son of Darius; among the Mohammedans he turned into a prophet, hot against idols; the pen of Christian monks made him an ascetic saint.

The Alexander romance found its way into Europe through the Latin versions of the pseudo-Callisthenes, not from the more sober narrative of Quintus Curtius. The pseudo-Callisthenes, in a recension which has not been preserved, was translated into Latin by Julius Valerius about the end of the 3rd century, and an epitome of this translation, also in Latin, was made some time before the 9th century, and is introduced by Vincent de Beauvais into his *Speculum historiale*. The first book deals with his birth and early exploits. The trace of Alexandrian influence is to be found in the pretence that his actual father was Nectanebus, a fugitive king of Egypt. The latter was a great magician, able, by operating upon waxen figures of the armies and ships of his enemies, to obtain complete power over their real actions. Obligated, however, to flee to Pella in Macedonia, he established himself as an astrologer, and as such was consulted by the childless Olympias. Having promised that Zeus Ammon would visit her in the form of a dragon, he himself assumed the disguise. In due course Alexander was born, and Philip's suspicions were overcome by a second appearance of the dragon, which was held to prove the divine fatherhood. The child was small and somewhat deformed, but of great courage and intelligence. When he was twelve years old he was instructed in starcraft by Nectanebus, who was killed by a fall into a pit, into which he had been playfully pushed by Alexander. The first book also relates his conquests in Italy, Africa, Syria and Asia Minor; his return to Macedonia and the submission of Greece. The second book continues the history of his conquests, and the third contains the victory over Porus, the relations with the Brahmans, the letter to Aristotle on the wonders of India, the histories of Candace and the Amazons, the letter to Olympias on the marvels of Farther Asia and lastly the account of Alexander's death in Babylon.

The most widespread Latin version of the story, however, was the *Historia de proeliis*, printed at Strasbourg in 1486, which began to supersede the *Epitome* of Julius Valerius in general favour about the end of the 13th century. It is said to have been written in the 10th century by the Neapolitan arch-presbyter Leo. Auxiliary sources for the mediaeval romance-writers were: the opusculum (4th century) known as *Alexandri magni iter ad Paradisum*, a fable of Eastern origin directed against ambition;

the *Itinerarium Alexandri* (340), based partly on Julius Valerius and dedicated to Constans, son of the emperor Constantine; the letter of Alexander to Aristotle (*Epist. de situ et mirabilibus Indiae*) and the correspondence between Alexander and the king of the Brahmins, Dindimus, both of which are often contained in mss. of the *Epitome*; and the treatise (based on a lost history of Alexander by Onesicritus), *De gentibus Indiae et Bragmanibus*,

THE CENOTAPH OF ALEXANDER THE GREAT AT CONSTANTINOPLE

ascribed without certainty to Palladius (d. c. 430), successively bishop of Helenopolis and Aspona.

In the Ethiopic versions we find the Greek gods in the guise of Enoch, Elijah, etc., while Philip is a Christian martyr, and Alexander himself a great apostle, even a saint; quotations from the Bible are frequent. Syriac and Armenian versions were made in the 5th century. Persians and Arabs told the deeds of Iskander; and Firdousi made use of the story in the *Shāhnāma*. Another early Persian poet, Nizami, made the story specially his own. In the 11th century Simeon Seth, *protovestiarius* at the Byzantine court, translated the fabulous history from the Persian back into Greek.

The Alexander legend was the theme of poetry in all European languages; six or seven German poets dealt with the subject, and it may be read in French, English, Spanish, Danish, Swedish, Icelandic, Flemish and Bohemian.

French.—The principal extant French romances based on the Alexander legend are: (1) A fragment by Alberic of Besançon (more properly Briançon), 11th century; (2) *Li romans d'Alexandre*, 12th century, by Alexandre de Bernai and other poets, in rhymed verse; (3) *l'Histoire du noble et vaillant roy Alixandre le Grant* (1506), a prose romance taken from the *Historia de proeliis*; and the *Alexandreis* (c.1180) of Gaultier de l'Isle or de Châtellon, a Latin poem based on Quintus Curtius.

English Versions.—The letter from Alexander to Aristotle and his correspondence with Dindimus are found in Early English versions dating from the 11th century. The Monk in Chaucer's *Canterbury Tales* prefaces his account of Alexander with the statement that his story is so common—

That every wight that hath discrecioun
Hath herd somewhat or all of his fortune.

There exist fragments of an English alliterative romance on the subject written in the west midland dialect, dating from the second half of the 14th century. Another alliterative poem in the northern dialect, of 15th-century origin, is based on the *Historia de proeliis*. Earlier than any of these is the rhyming *Lyfe of Alisaunder* (c. 1330), which is printed in H. Weber's *Metrical Romances* (vol. i., 1810). The *Scots Buik of the most noble and vailyzeand Conqueror Alexander the Great*, printed by Alexander Arbuthnot (d. 1585) about 1580, reprinted in 1831 for the Bannatyne Club, contains three episodes of the cycle, the "Forray of Gadderis" (not taken from the *Fuerre de Gadres*, but from the *Assaut de Tyr* in the *Romans d'Alexandre*), "The Avowes of Alexander" and "The Great Battel of Effesoun," taken from the *Voex du paon*. A *Buke of the Conqueror Alexander the Great* by Sir Gilbert Hay (fl. 1456) is in ms. at Taymouth Castle.

BIBLIOGRAPHY.—The best sketch of the Alexander romance literature is by Paul Meyer, *Alexandre le grand dans la littérature française*

au moyen âge (1886). The first volume contains some French texts, and the second a detailed discussion of the various versions from the pseudo-Callisthenes downwards. See also J. Zacher, *Pseudo-Callisthenes, Forschungen zur . . . Alexandersage* (Halle, 1867), and for Oriental versions, T. Nöldeke, "Beiträge zur Geschichte des Alexanderromans" (*Denkschriften der ksl. Akad. d. Wissenschaften, Phil.-hist. Klasse*, vol. 38: Vienna, 1890). For early printed versions see Brunet, *Manuel du libraire*, s.v. "Alexandre."

The text of the pseudo-Callisthenes was edited by C. W. Müller from three mss. in the Bibl. Nat. and printed in the Arrian of the Coll. Didot (Paris, 1846), and by H. Meusel (Leipzig, 1871) from a Leyden ms. A. Mai ed. Julius Valerius (Milan, 1817). *Itinerarium Alexandri* (Class. Auct. vol. vii.; Milan, 1835); J. Zacher, *Alex. iter ad Paradisum* (Regensburg, 1859); and the *Epitome* (Halle, 1867); the Oxford ms. of the *Epitome* was edited by G. Cilli (Strasbourg, 1905); G. Landgraf, *Die "Vita Alexandri" . . . des Archpresbyter Leo (Historia de proeliis)* (Erlangen, 1885); Alexander's letter to Aristotle and his correspondence with Dindimus are included in the Teubner edition of Julius Valerius (ed. B. Kübler, Leipzig, 1888). A newly discovered anonymous *Epitome* was edited by O. Wagner (Leipzig, 1900).

The fragment by Alberic was edited by P. Heyse (Berlin, 1856); Lamprecht's German text by H. Weismann (Frankfurt, 1850) and by C. Kinzel (Halle, 1884); the *Alexandreis* of Gaultier de Lille, by F. A. Müldener (Leipzig, 1863); an Icelandic prose version (c. 1250) of the same, *Alexanders Saga*, by C. R. Unger (Christiania, 1848); *Li Romans d'Alexandre*, by H. Michelant (Stuttgart, 1846); the Ethiopic version by E. A. T. Wallis Budge (1896, with English translation); the Syriac text of pseudo-Callisthenes by Budge (Cambridge, 1880).

Besides the English editions quoted in the text, the alliterative English poems were partially edited by J. Stevenson for the Roxburghe Club (1849). There is a great deal of information on the various texts in H. L. Wood's *Catalogue of Romances in the British Museum* (1883, vol. i., pp. 94 et seq.). Among other works see E. Rohde, *Der griechische Roman* (2nd ed., Leipzig, 1900); F. Kampers, "Alex. d. Grosse und die Idee des Weltimperiums in Prophetie und Sage" (in H. Granert's *Studien*, etc., Freiburg, 1901); Adolf Ausfeld, *Der griechische Alexanderroman* (Leipzig, 1907), edited after the author's death by W. Kroll.

ALEXANDER (1461–1506), king of Poland, succeeded his brother John Albert in 1501. He carried on the hopeless struggle of the crown against the growing power of the Polish senate and nobles, who deprived him of financial control and curtailed his prerogative. For want of funds, Alexander was unable to assist the Grand Master of the Order of the Sword against Muscovite aggression, or prevent Tsar Ivan III. from ravaging Lithuania with the Tartars. The utmost the king could do was to garrison Smolensk and other fortresses and employ his wife Helena, the tsar's daughter, to mediate a truce between his father-in-law and himself. Only the death of Stephen, the great hospodar of Moldavia, enabled Poland still to hold her own on the Danube. The liberality of Pope Julius II., who granted Alexander Peter's Pence and other financial help, enabled the Polish king to restrain somewhat the arrogance of the Teutonic Order in the Prussian provinces. Alexander died on Aug. 5, 1506.

See V. Czerny, *The Reigns of John Albert and Alexander Jagiello* (Pol.) (Cracow, 1882).

ALEXANDER I. (c. 1078–1124), king of Scotland, was the fourth son of Malcolm Canmore by his wife Margaret. On the death of his brother Edgar in 1107 he became king of Scotland north of the Forth and Clyde, southern Scotland being reserved for his brother David. He founded many abbeys and bishoprics, among them Inchcolm and Scone. He died April 27, 1124 (see SCOTLAND, *History*).

ALEXANDER II. (1198–1249), king of Scotland, son of William the Lion, whom he succeeded in 1214. He joined the English barons in their struggle against King John, marched into England and besieged Norham Castle in 1215. In 1217 he again invaded England but eventually made peace with Henry III., and the understanding was strengthened by his marriage with Henry's sister, Joanna, in 1221.

Peace with England was broken over a claim by Henry for homage from the Scottish king, and again by a threat of invasion in 1243, but both disputes were amicably settled. Alexander attempted to reduce the Western Isles, which were dependent on Norway, as he had already reduced Argyll, but while on an expedition for the purpose he died at Kerrera July 8, 1249.

ALEXANDER III. (1241–1285), king of Scotland, son of Alexander II. by his second wife Mary de Coucy, succeeded to

the throne in 1249, at the age of eight. The years of his minority were marked by an embittered struggle for the control of affairs between two rival parties, the one led by Walter Comyn, earl of Menteith, the other by Alan Durward, the justiciar. At the marriage of Alexander to Margaret of England in 1251, Henry III. seized the opportunity to demand from his son-in-law homage for the Scottish kingdom, but the claim was refused.

On attaining his majority, Alexander laid formal claim before the Norwegian king Haakon for sovereignty over the Hebrides, where Scandinavians had settled since the 9th century. Haakon replied by a formidable expedition in 1263. Sailing round the west coast of Scotland he halted off Arran, where negotiations were opened. These were prolonged by Alexander until the autumn storms should begin. At length Haakon attacked only to encounter a terrific storm which greatly damaged his ships. The battle of Largs (Oct. 12, 1263) was indecisive. But even so Haakon's position was hopeless. Baffled he turned homewards, but died on the way.

In 1266 Haakon's successor concluded a treaty by which the Isle of Man and the Western Isles were ceded to Scotland in return for a sum of 4,000 marks in four yearly payments, Orkney and Shetland alone being retained for Norway. The marriage of Alexander's daughter, Margaret, to Eric, son of King Magnus, was also agreed. Towards the end of Alexander's reign, the death of all his three children within a few years made the question of the succession one of pressing importance.

In 1284 he induced the Estates to recognize as his heir-presumptive his grand-daughter Margaret, the "Maid of Norway," and next year the desire for a male heir led him to contract a second marriage. Alexander was killed by a fall from his horse in the dark while riding to visit the queen at Kinghorn on March 16, 1285. The "Lament for Alisaunder," cited by Wynton, written in praise of Alexander III., is one of the earliest Scottish poems extant.

ALEXANDER (ALEXANDER OBRENOVICH) (1876-1903), king of Serbia, was born on Aug. 14, 1876. On March 6, 1889, his father, King Milan, abdicated and proclaimed him king of Serbia under a regency until he should attain his majority at 18 years of age. King Alexander, on April 13, 1893, being then in his 17th year, proclaimed himself of full age, and took the royal authority into his own hands. His action was popular, and was rendered still more so by his appointment of a radical ministry.

In May 1894 King Alexander abolished the liberal constitution of 1889 and restored the conservative one of 1869. His attitude during the Turco-Greek war of 1897 was one of strict neutrality. In 1898 he appointed his father commander-in-chief of the Serbian Army, and from that time, or rather from his return to Serbia in 1894 until 1900, ex-King Milan was regarded as the *de facto* ruler of the country. But while, during the summer of 1900, Milan was at Carlsbad making arrangements to secure the hand of a German princess for his son, King Alexander suddenly announced his engagement to Mme. Draga Mashin, a widow, formerly a lady-in-waiting to Queen Natalie. Ex-King Milan gave up his post, the government resigned, and King Alexander had great difficulty in forming a new cabinet. But the Tsar Nicholas congratulated the king on his engagement and agreed to act as principal witness at the wedding. The marriage was celebrated on Aug. 5, 1900.

Alexander tried to reconcile political parties by granting on his own initiative a liberal constitution (April 6, 1901), introducing for the first time in the constitutional history of Serbia the system of two chambers (*skupshchina* and senate). This did not reconcile the army, which was alarmed by the rumour that one of the

OF ALEXANDER III., KING OF SCOT.
LAND, HONOURED BY HIS PEOPLE
AS THE LAST OF THE "KINGS OF
PEACE"

two unpopular brothers of Queen Draga, Lieut. Nicodiye, was to be proclaimed heir-apparent. Meanwhile Alexander suspended (March 1903) the constitution for half an hour, time enough to publish the decrees by which the old senators and councillors of state were dismissed and replaced by new ones. This arbitrary act naturally increased the general discontent. It was thought that with a packed senate and a large government majority in the *skupshchina* King Alexander would not hesitate any longer to proclaim Queen Draga's brother as the heir to the throne. Ostensibly to prevent this, but in reality to replace Alexander Obrenovich by Peter Karagjorgjević, a military conspiracy was organized. The conspirators penetrated into the palace and savagely murdered King Alexander and Queen Draga in the early morning of June 11, 1903. (See SERBIA: History.)

ALEXANDER I., king of the Serbs, Croats and Slovenes (1888-), was born at Cetinje on Dec. 4, 1888, the second son of Prince Peter Karagjorgjević, later king of Serbia, and of Zorka, third daughter of Prince Nicholas of Montenegro. His mother died in 1890, and during his early years he shared the exile of his father at Geneva. In 1899 he was sent to St. Petersburg (Leningrad) to be educated, and in 1904 entered the *corps des pages* at the tsar's court. It was not till 1909, nearly six years after his father's election to the Serbian throne, that the young prince came to reside permanently in Serbia. Soon after his return his elder brother, Prince George, was obliged to renounce the succession (March 1909), owing to his unbalanced temperament, and various incidents that occurred during the Bosnian crisis; and Alexander was thereupon formally recognized as crown prince. On the outbreak of the Balkan war (1912) he assumed nominal command of the 1st Army and won his spurs at the battle of Kumanovo, subsequently serving with distinction in the campaigns against Turkey and Bulgaria.

On June 24, 1914 King Peter, whose health had completely broken down, appointed him prince regent, and he thus held the position of commander-in-chief when the World War broke out. He remained permanently at army headquarters, and shared with his soldiers all the privations of the retreat through Albania. On reaching the coast he fell ill and underwent a serious operation, but when already convalescent resolutely declined the proffered assistance of an Italian destroyer which had been sent to convey him across the Adriatic; he remained till all the refugees had been transported into safety, and eventually found his way on foot to Durazzo. After the exiled Serbian Government had established itself at Corfu, Prince Alexander and M. Pašić paid visits to Paris and London, where the prince was received with warm ovations. On April 5, 1916, on receiving an important deputation of British sympathizers (led by the archbishop of Canterbury, the lord mayor, Lord Milner and Sir Edward Carson), he publicly identified the dynasty with the cause of unity, expressing his conviction that in the final victory "our Yugoslav people, united in a single state, will have their part."

During the rest of the War he remained at Serbian headquarters and shared his army's victorious advance in Oct. 1918. On Dec. 1 delegates of the Yugoslav National Council in Zagreb formally recognized him as regent in all the Yugoslav provinces of the former dual monarchy, and he assumed the title of "prince-regent of the Serbs, Croats and Slovenes." The attempt made upon his life on June 29, 1921, after he had taken the oath the previous day to the new Yugoslav constitution, was the outcome, not of any personal unpopularity, but of the subversive aims of the Communists and other revolutionary groups, who hoped to create confusion in the new state, owing to the lack of a direct heir to the throne. On Aug. 16, 1921 Prince Alexander succeeded his father as king of Yugoslavia. On June 8, 1922 he married Marie, second daughter of King Ferdinand of Rumania, and on Sept. 6, 1923 an heir was born, who received the name of Peter, a second son being called after Tomislav, the first Croatian king.

King Alexander inherited from his father a respect for constitutional and parliamentary traditions, which was conspicuously lacking in his predecessors of the Obrenović dynasty;

and his influence has been repeatedly exercised behind the scenes to smooth down the acerbities of party strife. It was very largely due to his insistence that a reconciliation was achieved between the Serbian Radicals under M. Pašić and the Croat Peasant Party under M. Radić in the summer of 1925—an event which contributed greatly towards the political consolidation of Yugoslavia. (R. W. S.-W.)

ALEXANDER (ALEXANDER OF BATTENBERG) (1857–1893), first prince of Bulgaria, born on April 5, 1857, was the second son of Prince Alexander of Hesse and the Rhine by hismorganatic marriage with Julia, Countess von Hauke, who received the title of princess of Battenberg. Prince Alexander was nephew of the Tsar Alexander II., who had married a sister of Prince Alexander of Hesse. In his boyhood and early youth he was frequently at St. Petersburg (now Leningrad), and he accompanied his uncle during the Bulgarian campaign of 1877. When Bulgaria under the Berlin Treaty was constituted an autonomous principality under the suzerainty of Turkey, Prince Alexander was elected prince of Bulgaria at the instance of the tsar. He was at that time serving in the guards at Potsdam. He travelled to Bulgaria via St. Petersburg, and took the oath to the new constitution at Trnovo on July 8, 1879. The new ruler was 22 years of age, and chose his advisers at first from the Russophil conservative side, and, finding the liberals irreconcilable, he suddenly (May 9, 1881) issued a proclamation demanding absolute power for himself for seven years and appointing a Russian general, Ernroth, as head of the administration. This edict was ratified by a Grand Sobranje summoned for the purpose. But Alexander found himself in reality under the tutelage of two Russian generals, Soboleff and Alexander Kaulbars, sent from St. Petersburg. He chafed under the restraint, joined hands with his subjects, and restored the constitution (Sept. 18, 1883). The consequent breach with Russia was widened in 1885 when Alexander, who had been forewarned of the *coup d'état* at Philippopolis which deposed the governor-general of Eastern Rumelia and proclaimed union with Bulgaria, entered Philippopolis on Sept. 21 and assumed the government.

The tsar struck his nephew's name off the Russian army list, and recalled the Russian officers. Alexander strengthened his position by his brilliant defence against the Serbian invasion and the victory at Slivnitsa, Nov. 16–19, and the capture of Pirof. The sultan, in 1886, agreed that Alexander should be governor-general of Eastern Rumelia for five years. The Bulgarians would have liked a more explicit arrangement, and on the night of Aug. 20, 1886, the prince was kidnapped, compelled to abdicate, and handed over to the Russians. In a fortnight he was back at Sofia, but an abject telegram to the tsar had destroyed his prestige with his subjects, and the hostility of the tsar and of Bismarck drove him to abdicate in earnest on Sept. 8, 1886.

He spent the rest of his life principally at Graz, where he died on Oct. 23 1893.

See especially E. G. Costi, *Fürst Alexander von Battenberg* (2nd ed. Vienna, 1928); also Koch, *Fürst Alexander von Bulgarien* (Darmstadt, 1887; English translation, 1887); Matveyev, *Bulgarien nach dem Berliner Congress* (Petersburg, 1887); Bouchier, "Prince Alexander of Battenberg," in *Fortnightly Review*, Jan. 1894.

ALEXANDER, despot of Pherae in Thessaly from 369 to 358 B.C. His tyranny caused the Aleuadae of Larissa to invoke the aid of Alexander II. of Macedon, but after his withdrawal Alexander treated his subjects as cruelly as before. The Thessalians now applied to Thebes; Pelopidas, who was sent to their assistance, was treacherously thrown into prison (368), and it was necessary to send Epaminondas with a large army to secure his release. Alexander's conduct caused renewed intervention; in 364 he was defeated by the Thebans at Cynoscephalae, where Pelopidas fell. Alexander was at last compelled by Thebes to acknowledge the freedom of the Thessalian cities, to limit his rule to Pherae, and to join the Boeotian league. He was murdered by his wife's brother at her instigation.

ALEXANDER, son of Numenius, Greek rhetorician, flourished in the first half of the second century A.D., author of a treatise on rhetoric (*Περὶ τῶν τῆς διαβολῆς καὶ τῆς λέξεως σχημάτων*), of which only an abridgment is extant; it was fol-

lowed as an authority by later writers. Later epitomes were made in Latin by Aquila Romanus and Julius Rufinianus under the title *De Figuris Sententiarum et Elocutionis*.

Text in Spengel, *Rhetores Graeci* (1856).

ALEXANDER, DE ALVA STANWOOD (1845–1925), American lawyer and political historian, was born in Richmond, Me., on July 17, 1845. He enlisted in the Union army in 1862 and served until the end of the Civil War. Following his graduation at Bowdoin college, Brunswick, Me., in 1870, he was editor of the *Daily Gazette*, Ft. Wayne, Ind., in 1871–74, and was secretary of the Indiana Republican State committee in 1874–78. He was admitted to the bar and practised law in Indianapolis, Ind., from 1877 to 1881, served in the U.S. Treasury department from 1881 to 1885, and then resumed law practice in Buffalo, New York. Engaging in politics, he was elected Republican representative in Congress for seven consecutive terms, 1897–1911. He died in Buffalo, N.Y., on Jan. 29, 1925.

He published a valuable *Political History of the State of New York* (1906–09); *History and Procedure of the House of Representatives* (Boston, 1916) and *Four Famous New Yorkers* (1923), a continuation of his *Political History*.

ALEXANDER, SIR GEORGE (1858–1918), English actor, whose family name was Samson, was born in Reading on June 19, 1858, and died on March 16, 1918. He made his first appearance on the London stage as Caleb Deecie in *Two Roses* in 1881 with Irving at the Lyceum. In 1891 he became manager of the St. James's theatre. There he produced a number of successful plays by Oscar Wilde, Pinero, C. Haddon Chambers, H. A. Jones, Alfred Sutro and others, he himself taking the leading rôles. Sir George Alexander was the type of the successful actor-manager on the London stage in the beginning of the 20th century. In 1907 he was elected a member of the London County Council as a municipal reformer. He received a K.C.B. in 1911.

ALEXANDER, SIR JAMES EDWARD (1803–1885), British general and traveller, was born on Oct. 16, 1803, and died on April 2, 1885. He was largely responsible for the preservation and transfer to England of the obelisk, Cleopatra's Needle, in 1877.

His varied experiences provided material for a large number of books, among which were *Travels from India to England* (1827); *Transatlantic Sketches* (1833); *An Expedition of Discovery into the Interior of Africa* (1838).

ALEXANDER, JEROME (1876–), American chemist, was born in New York city, on Dec. 21, 1876. He graduated in 1896 from the College of the City of New York from which in 1899 he received the degree of master of science. He was an official and chief chemist for various companies from 1896 until 1921, when he began individual practice as consulting chemist and engineer. In connection with this work he specialized in the chemistry of colloids and was an early investigator in America with the ultramicroscope. He published *Colloid Chemistry* (1919) and, in collaboration with numerous scientists, *Colloid Chemistry, Theoretical and Applied* (1926). In 1909 he translated Richard Zsigmondy's *Colloids and the Ultramicroscope*. His writings include also the sections "Glue and Gelatin" and "Colloid Chemistry" in Roger's *Industrial Chemistry* (1912), the article "Albuminoids or Scleroproteins" in Allen's *Commercial Organic Analysis* (1913), and the chapter "Colloid Chemistry" in Liddell's *Handbook for Chemical Engineers* (1920).

ALEXANDER, JOHN WHITE (1856–1915), American painter, was born in Allegheny (Pa.), Oct. 7, 1856. He was left an orphan when very young, became an illustrator for *Harper's Magazine*, studied in Europe, became a pupil of the Royal Academy at Munich, and also worked in Venice, in Holland and in Paris, where he attracted much attention by his exhibition at the Salon of two female portraits entitled "Gris" and "Noir." He became a member of the Société Nationale des Beaux Arts (Paris), of the National Academy of Design (New York), of which he was president 1909–15, of the International Society (London), and of the Vienna and Munich societies of painters. In 1901 he was made a Chevalier of the Legion of Honour. He

executed decorative panels for the Congressional library, Washington (D.C.), and a large decoration for the Carnegie institute, Pittsburgh (Pa.), and his works include numerous portraits and subject pictures. He died in New York June 1, 1915.

ALEXANDER, WILLIAM (1824-1911), Protestant archbishop of Armagh and primate of all Ireland, was born at Londonderry on April 13, 1824, and educated at Tonbridge school and Brasenose college, Oxford. He was made bishop of Derry and Raphoe in 1867, and was elevated to the primacy in 1896. His poems were collected in 1887 under the title of *St. Augustine's Holiday, and other Poems*.

His wife, CECILE FRANCES HUMPHREYS (1818-1895), wrote some tracts in connection with the Oxford movement, but is famous as the author of "Jesus calls us o'er the tumult," "There is a green hill far away," and other well-known hymns (nearly 400 in all). A collection of her verse was published in 1896.

ALEXANDER, WILLIAM LINDSAY (1808-1884), Scottish divine, born at Leith, Aug. 24, 1808, and died Dec. 20, 1884. Educated at St. Andrews and Edinburgh, he was classical tutor at the Blackburn Theological Academy (1827), minister of North College street church, Edinburgh (1834), editor of Kitto's *Biblical Encyclopaedia* (1861), a member of the committee appointed to revise the Old Testament (1870), and principal of the Edinburgh Theological Hall (1877).

ALEXANDER AETOLUS, of Pleuron in Aetolia, Greek poet and man of letters, flourished about 280 B.C. He was commissioned by Ptolemy Philadelphus to arrange the tragedies and satyric dramas in the library of Alexandria; in 276 he went to the court of Antigonos Gonatas, king of Macedonia. He was one of the Alexandrian tragic Pleiad. We know the title of only one of his plays (*Astragalistae*). He also wrote short epics, epigrams, and elegies, the considerable fragments of which show learning and eloquence.

Meineke, *Analecta Alexandrina* (1853); Bergk, *Poetae Lyrici Graeci*; Couat, *La Poésie alexandrine* (1882).

ALEXANDER BALAS (i.e., "lord"), a native of Smyrna of humble origin, gave himself out to be the son of Antiochus IV. Epiphanes and heir to the Syrian throne. His claims were recognized by the Roman senate. At first unsuccessful, he finally defeated the reigning king Demetrius Soter in 150 B.C. and made himself king. But in 146 Demetrius' son, with the help of Alexander's father-in-law, Ptolemy Philometor, defeated him in a pitched battle near Antioch in Syria. He fled for refuge to a Nabataean prince, who murdered him.

See 1 Maccab. 10 et seq.; Justin xxxv. 1 and 2; Josephus, *Antiq.* xiii. 2; Appian, *Syr.* 67; Polybius xxxiii. 14.

ALEXANDER CORNELIUS, Greek grammarian surnamed POLYHISTOR from his great learning, born at Miletus, became a Roman citizen in 82 B.C., after being taken prisoner in the Mithridatic war. Of the extant fragments of his works (which were mainly historical and geographical) (Mueller, *Fragmenta Historicorum Graecorum*, iii.), those relating to the Jews are important as containing quotations from lost Jewish authors.

ALEXANDER JOHN, FIRST PRINCE OF RUMANIA: see CUZA, ALEXANDER JOHN.

ALEXANDER NEVSKI (1220-1263), Russian hero and saint, grand duke of Vladimir, spent the early years of his life in constant warfare with the Germans, Swedes and Lithuanians, who sought to rescue Novgorod and Pskov from Russia. He is called Nevski from his victory over the Swedish general, Birger Jarl, on the banks of the Neva (July 15, 1240). Two years later his defeat of the knights of the Teutonic Order on Lake Peipus (April 5) compelled them to renounce their conquests. In 1252 the grand khan appointed Alexander grand-duke of Vladimir in place of his elder brother Andrew. Alexander thenceforth did his best to prevent any possible pretext for a new Tatar invasion. In 1262 he obtained a mitigation of the tribute, and the abolition of the military service hitherto rendered by the Russians to the Tatars. The Orthodox Church canonized Alexander for his services to his country.

See Sergeyi Mikhailovich Solov'ev, *History of Russia* (Russ. 2nd ed. 1897, vol. iii.).

ALEXANDER OF APHRODISIAS, pupil of Aristocles of Messene, Greek commentator on the writings of Aristotle, and styled, by way of pre-eminence, *ὁ ἐξηγητής* ("the expositor"), was a native of Aphrodisias in Caria. He came to Athens towards the end of the 2nd century A.D., became head of the Lyceum and lectured on peripatetic philosophy. The object of his work was to free the doctrine from the syncretism of Ammonius and to reproduce the pure doctrine of Aristotle. Commentaries by Alexander on the following works of Aristotle are still extant: *The Analytica Priora*, i.; the *Topica*; the *Meteorologica*; the *De Sensu*; and the *Metaphysica*, i.-v., together with an abridgment of what he wrote on the remaining books of the *Metaphysica*. The most important of Alexander's other extant works are *On Fate*, in which he argues against the Stoic doctrine of necessity; and *On the Soul*, in which he contends that the undeveloped reason in man is material (*νοῦς ὕλικός*) and inseparable from the body. He argued strongly against the doctrine of immortality. He identified the active intellect (*νοῦς ποιητικός*), through whose action the potential intellect in man becomes actual, with God.

Several of Alexander's works were published in the Aldine edition of Aristotle (Venice, 1495-98); his *De Fato* and *De Anima* were printed along with the works of Themistius at Venice (1534); the former work, which has been translated into Latin by Grotius and also by Schultess, was edited by J. C. Orelli (Zürich, 1824); and his commentaries on the *Metaphysica* by H. Bonitz (Berlin, 1847). J. Nourissou has treated of his doctrine of fate, *De la liberté et du hasard* (Paris, 1870).

See PERIPATETICS (*ad fin.*); ALEXANDRISTS; POMPONAZZI, PIETRO; also A. Apelt, "Die Schrift d. Alex. v. Aphr.," *Philologus*, xlv. (1886); C. Ruelle, "Alex. d'Aphr. et le prétendu Alex. d'Alexandrie," *Rev. des études grecques*, v. (1892); E. Zeller's *Outlines of Gk. Phil.* (Eng. trans. ed. 1905, p. 296).

ALEXANDER OF HALES (ALEXANDER HALENSIS), known as DOCTOR IRREFRAGABILIS, was one of the first English scholars and theologians to make his influence felt in Paris. Born c. 1175 in Gloucestershire, he went to study at Paris, where he became a master of arts sometime before 1210. About 1231 he entered the Friars Minor, and after his appointment as the first *magister regens* of the chair of theology held by his order in the university became celebrated as a teacher. John of Rochelle, Bonaventura and probably Roger Bacon were among his pupils. He died in 1245. Roger Bacon tells us that Alexander's *Summa Theologiae* weighed more than a horse and was not entirely of his own composition. The latter statement is well substantiated, and pending publication of the critical edition which is being made by the Franciscans of Quaracchi little can be said with certainty about Alexander's theories. However, we know that he attempted to correlate the predominating Augustinianism of his day with the newly introduced philosophy of Aristotle and the Arabians, and apart from the doctrines that were common to the scholastics (see SCHOLASTICISM) we find in him certain theories that were to become characteristic of the Franciscan school. Thus he admits the plurality of forms, the independence of body and soul, the existence of an intelligible matter or potency in all spiritual creatures, and the Augustinian theory of Divine Illumination in knowledge. Alexander's *Summa Theologiae* (best edition, Venice 1576) was extensively utilized by Albert the Great, St. Thomas, and St. Bonaventura.

Études Juives* (1890) and *Die Scholastik des dreizehnten Jahrhunderts in ihren Beziehungen zum Judentum* (1902); P. Mingès, *Zur Psychologie des A. von H.* in *Philos. Jahrb.* (1915).

ALEXANDER OF TRALLES (ALEXANDER TRALLIANUS), Greek physician, born at Tralles in Lydia, lived probably about the middle of the 6th century B.C. The Greek text of his *Βυβλία ἰατρικά* was printed at Paris in 1548 and his *De Lumbricis* at Venice in 1570.

See E. Milward, *Trallianus Reviviscens* (1734).

ALEXANDER SEVERUS (MARCUS AURELIUS SEVERUS ALEXANDER) (208-235), Roman emperor from A.D. 222 to 235, was born at Arca Caesarea, in Palestine, on Oct. 1, 208. He was the son of an imperial procurator. In 221 his grandmother, Julia Maesa, persuaded her nephew, the emperor Heliogabalus, to adopt him as successor and create him Caesar. In the next year, on

March 11, Heliogabalus was murdered, and Alexander was proclaimed emperor by the Praetorians and accepted by the senate. He was then a mere lad, amiable, well-meaning, but entirely under the dominion of his mother, Julia Mamaea, who surrounded him with wise counsellors, but who alienated the army by extreme parsimony, while neither she nor her son had a strong enough hand to keep tight the reins of military discipline. Mutinies became frequent in all parts of the empire; to one of them the life of the jurist and praetorian praefect, Ulpian, was sacrificed; another compelled the retirement of Dio Cassius from his command. On the whole, however, the reign of Alexander was prosperous till he was summoned to the East to face the new power of the Sassanians (see PERSIA: History). Of the war that followed we have very various accounts; Mommsen leans to that which is least favourable to the Romans. At all events, though the Persians were checked for the time, the conduct of the Roman army showed an extraordinary lack of discipline. The emperor returned to Rome and celebrated a triumph (233), but next year he was called to face German invaders in Gaul, where he was slain (on March 18 or 19, 235), together with his mother, in a mutiny which was probably led by Maximinus, a Thracian legionary, and at any rate secured him the throne. Alexander was the last of the Syrian princes. His advisers were the famous jurist, Ulpian, the historian, Dio Cassius, and a select board of 16 senators; a municipal council of 14 assisted the city praefect in administering the affairs of the 14 districts of Rome. The luxury and extravagance that had formerly been so prevalent at the court were put down; the standard of the coinage was raised; taxes were lightened; literature, art and science were encouraged; the lot of the soldiers was improved; and, for the convenience of the people, loan offices were instituted for lending money at a moderate rate of interest. In religious matters Alexander preserved an open mind. In his private chapel he had busts of Orpheus, Abraham, Apollonius of Tyana and Jesus Christ.

Hönn, *Quellenuntersuchungen zu den Viten des Heliogabalus und des Severus Alexander* (1911).

ALEXANDER THE PAPHLAGONIAN, a celebrated impostor and worker of false oracles, was born at Abonouteichos (see INEBOLI) in Paphlagonia in the early part of the 2nd century A.D. The vivid narrative of his career given by Lucian might be taken as fictitious but for the corroboration of certain coins of the emperors Lucius Verus and Marcus Aurelius (J. H. Eckhel, *Doctrina Nummorum Veterum*, ii., p. 383, 384) and of a statue of Alexander, said by Athenagoras (*Apology*, c. 26) to have stood in the forum of Parium. Alexander succeeded in establishing an oracle of Aesculapius at his native town. Having circulated a prophecy that the son of Apollo was to be born again, he contrived that there should be found in the foundations of the temple to Aesculapius, then in course of construction at Abonouteichos, an egg in which a small live snake had been placed. Alexander had little difficulty in convincing the Paphlagonians of the second coming of the god under the name of Glycon. A large tame snake with a false human head, wound round Alexander's body as he sat in a shrine in the temple, gave "autophones" or oracles unasked, but the usual methods practised were those of the numerous oracle-mongers of the time, of which Lucian gives a detailed account, the opening of sealed enquiries by heated needles, a neat plan of forging broken seals, and the giving of vague or meaningless replies to difficult questions. The reputation of the oracle spread, and Alexander set up an "intelligence bureau" in Rome, instituted mysteries like those of Eleusis, from which the Christians and Epicureans were alike excluded as "profane," and celebrated a mystic marriage between himself and the moon. Lucian's own close investigations into Alexander's methods of fraud led to a serious attempt on his life. The whole account gives a graphic description of the inner working of one among the many new

oracles that were springing up at this period. Alexander lived to be seventy and amassed great sums of money.

ALEXANDER ARCHIPELAGO, a maze of about 1,100 islands and islets (area about 13,000sq.m.) lying close inland off the south-west coast of Alaska, U.S.A., situated between 54° 40' and 58° 30' N. They are the remnant of a submerged mountain system; the islands rise 3,000 to 5,000ft. above the sea with luxuriantly wooded tops and bold sheer sides scarred with marks of glacial action. In some respects the scenery is similar to that of Norway. Through the inner channels, sheltered from the Pacific by the island ramparts, runs the "inland passage," the tourist route northward from Seattle, Washington. The principal islands from north-west to south-east are Chicagof, Baranof, Admiralty, Kupreanof, Kuiu, Prince of Wales (the largest of the archipelago and of all the islands about Alaska, measuring about 140m. in length and 40m. in width), Etolin and Revillagigedo. Sitka, the former capital, is on the west coast of Baranof island.

ALEXANDERS (botanical name, *Smyrniolum olusatrum* family Umbelliferae), a stout herbaceous plant with a furrowed, much-branched stem 1-3ft. high, and large compound leaves with broad sheathing stalks, and broad, cut or lobed segments. The small yellow flowers are borne in compound umbels. The plant is a native of the Mediterranean region, and was formerly cultivated as a pot-herb. It is now found apparently wild in the British Isles. In the United States the name is applied to the meadow-parsnip (*Zizia*), as golden alexanders (*Z. aurea*).

ALEXANDERSBAD, a watering-place, Bavaria, Germany, romantically situated in the Fichtelgebirge, near Wunsiedel, 1,900ft. above the sea. Its waters are ferruginous and largely used in nervous and rheumatic disorders. In the neighbourhood is the Luisenburg (or Luxburg), a hill commanding a fine view of the whole Fichtelgebirge.

ALEXANDERSON, ERNST F. W. (1878-), engineer and inventor, born at Uppsala, Sweden, Jan. 25, 1878. He early exhibited a strong aptitude for mechanics. After graduating from the Royal Technical university in Stockholm, he passed a year at the Royal Institute of Technology at Berlin. In 1901 he went to the United States; in 1902 he entered the draughting department of the General Electric Company at Schenectady, two years later becoming a member of the engineering staff. During his 25 years with the General Electric Company he took out more than 200 patents, many of them significant in the advance of the electrical art. He has done valuable work in railway electrification and electric ship propulsion. His contributions are in the field of radio, and probably the best known of these is the Alexanderson high frequency alternator, which, in conjunction with the magnetic amplifier and multiple tuned antenna, has been extensively used in commercial long-wave trans-oceanic radio communication. His invention employing the high-power vacuum tube for relaying and modulation forms the basis of all broadcasting transmitters. The Alexanderson system of tuned radio frequency reception has made possible the modern selective receiver, thus solving the problem of interference between the numerous transmitting stations. This system is used in the best receiving sets to-day. He has also developed and demonstrated a system of television and a system of broadcasting pictures by radio.

In 1920 the Radio Corporation of America was formed at the request of the U.S. Government to exploit the Alexanderson system of trans-oceanic radio telegraphy, which was used extensively during the World War. Alexanderson was lent by the General Electric Company to act as chief engineer of the new enterprise. Later, returning to his work at Schenectady, he was made chief consulting engineer of the Radio Corporation, while remaining a consulting engineer of the General Electric Company. He was at one time president of the Institute of Radio Engineers.

ALEXANDRA (1844-1925), Queen Consort of Edward VII., King of Great Britain and Ireland, eldest daughter of Prince Christian of Glücksburg, afterwards King Christian IX. of

Denmark, and Louise, daughter of the Landgrave William of Hesse, was born at Copenhagen Dec. 1, 1844, her full name being Alexandra Caroline Maria Charlotte Louisa Julia. One of her sisters married the tsar of Russia and became the mother of the Tsar Nicholas II. As a child Alexandra was simply brought up and early evinced a love of music and of fairy tales, being encouraged in this by her parents' friendship with Hans Andersen. She was married to Albert Edward, Prince of Wales, afterwards Edward VII., March 10, 1863, and was crowned with him in Westminster Abbey, Aug. 9, 1902.

Her singular beauty and charm—first celebrated in Tennyson's *A Welcome to Alexandra* (1863) when she came to England as a bride—preserved even into old age, won her immense popularity, and her progress through the streets of London on Alexandra Day, or Rose Day, a yearly event inaugurated by her in 1912 to raise funds for the London hospitals by the selling of roses in the streets, attracted vast crowds. She had earlier shown her great interest in the care of the sick by giving her name to the Queen Alexandra's Imperial Nursing Service, organized in 1902 to supply nurses for naval and military hospitals, as well as by her gift to the London Hospital in 1899 of the first Finsen lamp for light treatment of skin diseases. Her love of country life, and especially of horses and dogs, endeared her to a nation, like herself, lovers of animals. Though she took her full share in all public ceremonies, she was happiest in her country home at Sandringham. There in Dec. 1924 she kept her 80th birthday, surrounded by her children and grandchildren, and there she died Nov. 20, 1925. She was buried beside King Edward in St. George's Chapel, Windsor.

ALEXANDRE, NOËL (NATALIS ALEXANDER) (1639–1724), French theologian and ecclesiastical historian, born at Rouen, Jan. 19, 1639, was professor of philosophy at the convent of Saint-Jacques in Paris. He became provincial of his order in 1706, but was banished to Châtellerault in 1709 for having subscribed to the *Cas de conscience* (1703). He died in Paris, Aug. 21, 1724.

The best known of his numerous works is the *Selecta historiae ecclesiasticae capita, et in loca ejusdem insignia dissertationes historicae, chronologicae, dogmaticae* (1676–86), which was placed on the Index by Innocent XI. on account of his bold defence of the Gallican claims.

See *Catalogue complet des oeuvres du Père Alexandre* (1716); Quétiif-Echard, *Scriptores ordinis praedicatorum* (1719–21), t. ii. p. 810; and full bibliography in A. Vacant, *Dict. de Théologie* (scholarly article by P. Mandouret, cols. 769–772). Of the numerous editions of Alexandre's ecclesiastical history the best is that of P. J. D. Mansi, which contains many valuable notes and additions (Luca, 1749) and has been frequently reprinted.

ALEXANDRETTA, a city of Syria, on the gulf of the same name. Pop. 15,000, two-thirds Muslim. Iskanderun (its Turkish name) preserves the name but probably not the exact site of the city founded to commemorate Alexander's victory over the Persians at Issus (333 B.C.). The name "little Alexandria" appears to date from the 4th century A.D. The city is surrounded by a girdle of hills, spurs of the Cilician Taurus. Its site on marshy, deltaic ground has made it notoriously unhealthy, as an early epithet *scabiosa* indicates, and the yellow hue of the natives of to-day reflects the constant prevalence of fever. The British Levant (Turkey) Company maintained an agency and factory here for 200 years till 1825 in spite of appalling mortality among its employees. Alexandretta lies in the *état* Syria of French mandated territory and has attached to it a *sanjaq*. The Anatolian frontier reaches the sea 12m. to the north. A branch line (1913) connects Alexandretta to the north at Topra-Kale with the Baghdad railway. A journey to Aleppo thus involves crossing the frontier twice. Alexandretta was formerly the main outlet for the overland trade from Persia and India until the construction of the Suez Canal diverted this to shipboard. It still remains the main port

for the district of Aleppo, a connection with which by railway *via* Antioch is projected. It provides the only safe anchorage on the Syrian coast. There is as yet only a small boat harbour and transhipment of goods has to be effected by lighters in open roadstead, but French enterprise is expected to alter this. Imports are mainly cotton, silk and woollen goods as well as yarns, dyes and buffalo hides for the soles of native shoes. Exports include live stock (cattle and sheep to Egypt), textiles, tobacco, silk cocoons, pistachio nuts, oranges, lemons, liquorice and gall-nuts. Britain has here a vice-consul. Petroleum has been discovered south-west of Alexandretta, and antimony and chrome are reported to exist in the surrounding hills.

See *Admiralty Handbook of Syria* (1913); *Diplomatic and Consular Reports on Turkey*; *Reports on Syria of Department of Overseas Trade*.

ALEXANDRIA, a city and chief seaport of Egypt, and for over a thousand years from its foundation the capital of the country, situated on the Mediterranean in 31° 12' N., 29° 15' E., and 129m. by rail N.W. of Cairo. The ancient Canopic mouth of the Nile (now dry) was 12m. east.

I. The Modern City.—The city is built on the strip of land which separates the Mediterranean from Lake Mareotis (Mariut),

A BAZAAR STREET IN THE NATIVE QUARTER OF ALEXANDRIA, EGYPT. Alexandria, an important trading centre of Egypt, still retains after 2,000 years the cosmopolitan spirit engendered by its founder, Alexander the Great. It numbers among its inhabitants Egyptians, Greeks, Jews and Europeans and has industries ranging from the ancient oriental art of rug weaving to paper manufacture.

and on a T-shaped peninsula which forms harbours east and west. The stem of the T was originally a mole leading to an island (Pharos) which formed the cross-piece. In the course of centuries this mole has been silted up and is now an isthmus half a mile wide. On it a part of the modern city is built. The cape at the western end of the peninsula is Ras et-Tin (Cape of Figs); the eastern cape is known as Pharos or Kait Bey.

The customs house and chief warehouses are by the western harbour, but the principal buildings of the city are in the east

and south-east quarters. The Place Mehemet Ali, or Grand square, which is the centre of the life of the city and the starting-point of the electric tramways, is an oblong open space, tree-lined, in the centre of which there is an equestrian statue of the prince after whom it is named. The square is faced with handsome buildings mainly in the Italian style, including the law courts, exchange, Ottoman bank, English church and the Abbas Hilmi theatre. A number of short streets lead from the square to the eastern harbour. Here a sea wall, completed in 1905, provides a magnificent drive and promenade along the shore for a distance of about 3 miles. From the south end of the square the Rue Sherif Pasha—in which are the principal shops—and the Rue Tewfik Pasha lead to the boulevard, or rue, de Rosette. In it are the Zizinia theatre and the municipal palace (containing the public library); the museum, containing an excellent collection of antiquities, lies up a short street to the north. The western end of the boulevard leads to the Place Ibrahim, often called Place Ste. Catherine, from the Roman Catholic church at its south-east side. In a street running south from the boulevard to the railway station is the mosque of Nebi Daniel, containing the tombs of Said Pasha and other members of the khedivial family.

The north quarter, thoroughly oriental in style, is mainly occupied by Egyptians and Levantines. This Arab quarter is traversed by the Rue Ras et-Tin, leading to the promontory of that name. Here, overlooking the harbour, is the khedivial yacht club (built 1903) and the palace built by Mehemet Ali. In the district between the Grand square and the western harbour, one of the poorest quarters of the city, is an open space with Fort Caffarelli or Napoleon in the centre. This quarter has been pierced by several straight roads, one of which, crossing the Mahmudiya canal by the Pont Neuf, leads to Gabbari, the most westerly part of the city, and an industrial and manufacturing region, possessing asphalt works and oil, rice and paper mills. On either side of the canal are the warehouses of wholesale dealers in cotton, wool, sugar, grain and other commodities. In the southern part of the city are the Arab cemetery, "Pompey's Pillar" and the catacombs. "Pompey's Pillar" (A.D. 302), which stands on the highest spot in Alexandria, is nearly 99ft. high, including the pedestal. The shaft is of red granite and is beautifully polished. The catacombs, a short distance south-west of the pillar, are hewn out of the rocky slope of a hill, and are an elaborate series of chambers adorned with pillars, statues, religious symbols and traces of painting.

The eastern bay is rocky, shallow and exposed, and is now used only by fishing craft, though a breakwater to protect its quays was completed in 1916. The harbour is on the west of Pharos and partly formed by a breakwater (built 1871-73 and prolonged 1906-07), 2m. long. The breakwater starts opposite the promontory of Ras et-Tin, on which is a lighthouse, 180ft. above the sea, built by Mehemet Ali. Another breakwater starts from the Gabbari side, the opening between the two works being about half a mile. A number of scattered rocks lie across the entrance, but through them two fairways have been made, and the enclosed water is divided into an outer and inner harbour by a mole, 1,000yd. long, projecting north-west from the southern shore. The inner harbour covers 464 acres. It is lined for 2½m. by quays, affording accommodation for ships drawing up to 28ft. The outer harbour (1,400 acres water area) is furnished with a graving dock, 520ft. long, and with quays and jetties along the Gabbari foreshore.

Alexandria is linked by a network of railway and telegraph lines to the other towns of Egypt, and there is a trunk telephone line to Cairo. The city secured in 1906 a new and adequate water-supply, modern drainage works having been completed the previous year. Being the great *entrepôt* for the trade of Egypt, the city is the headquarters of the British chamber of commerce and of most of the merchants and companies engaged in the development of the Delta. Over 80% of the total exports and imports of the country pass through the port.

The population of the city, including the suburbs, in 1927 was 570,314. The foreigners numbered over 100,000, of whom the majority were Greeks, Italians, Syrians, Armenians and other Lev-

antines, though almost every European and Oriental nation is represented. The labouring population is mainly Egyptian; the Greeks and Levantines are usually shopkeepers or petty traders.

II. The Ancient City.—The Greek Alexandria was divided into three regions: (1) the Jews' quarter, forming the north-east portion of the city; (2) Rhacotis, on the west, occupied chiefly by Egyptians; (3) Brucheum, the Royal or Greek quarter, forming the most magnificent portion of the city. In Roman times Brucheum was enlarged by the addition of an official quarter, making up the number of four regiones in all. The city was laid out as a gridiron of parallel streets, each of which had an attendant subterranean canal; and the two main streets, lined with colonnades and said to have been each about 200ft. wide, intersected in the centre of the city. The island of Pharos was joined to the mainland by a mole nearly a mile long and called the Hep-tastadium. The end of this abutted on the land at the head of the present Grand square, where rose the "Moon Gate." All that now lies between that point and the modern Ras et-Tin quarter is built on the silt which gradually widened and obliterated this mole. The Ras et-Tin quarter represents all that is left of the island of Pharos, the site of the actual lighthouse having been weathered away by the sea. On the east of the mole was the great harbour, now an open bay; on the west lay the port of Eunostos, with its inner basin Kibotos, now vastly enlarged to form the modern harbour.

In Strabo's time (latter half of 1st century B.C.) the principal buildings were as follows, enumerated as they were to be seen from a ship entering the great harbour. (1) the royal palaces, filling the north-east angle of the town and occupying the promontory of Lochias, which shut in the great harbour on the east. Lochias, the modern Pharillon, has almost entirely disappeared into the sea, together with the palaces, the private port and the island of Antirrholdus. There has been a land subsidence here, as throughout the north Delta and indeed all the north-east coast of Africa; and on calm days the foundations of buildings may be seen, running out far under sea, near the Pharillon. (2) The great theatre, on the modern Hospital hill near the Ramleh station. This was used by Caesar as a fortress, where he stood a siege from the city mob after the battle of Pharsalus. (3) The Poseidon or temple of the sea-god, close to the theatre and in front of it. (4) the Timonium built by Anthony. (5, 6, 7) The Emporium (exchange), Apostases (magazines) and Navalia (docks), lying west of (4), along the sea-front as far as the mole. Behind the Emporium rose (8) the great Caesareum, by which stood the two obelisks, later known as "Cleopatra's Needles," and now removed to London and New York. This temple became in time the Patriarchal church, some remains of which have been discovered; but the actual Caesareum, so far as not eroded by the waves, lies under the houses lining the new sea-wall. (9) The Gymnasium and (10) the Palaestra are both inland, near the great Canopic street (Boulevard de Rosette) in the eastern half of the town, but on sites not determined. (11) The temple of Saturn: site unknown. (12) The Mausolea of Alexander (Soma) and the Ptolemies in one ring-fence, near the point of intersection of the two main streets. (13) The museum with its library and theatre in the same region; but on a site not identified. (14) The Serapeum, the most famous of all Alexandrian temples. Strabo tells us that this stood in the west of the city; and recent discoveries go far to place it near "Pompey's Pillar" (*see above*), which, however, was an independent monument erected to commemorate Diocletian's siege of the city. On the eastern point of the Pharos island stood the great lighthouse, one of the "Seven Wonders," reputed to be 400ft. high. The first Ptolemy began it, and the second completed it, at a total cost of 800 talents. It is the prototype of all lighthouses in the world. A temple of Hephaestus also stood on Pharos at the head of the mole.

III. History.—Founded in 332 B.C. by Alexander the Great, Alexandria was intended to supersede Naucratis as a Greek centre in Egypt, and to be at once a secure naval base for his designs on Persia and a link between Macedonia and the rich Nile valley. If such a city was to be on the Egyptian coast, there was only one possible site, behind the screen of the Pharos island and

removed from the silt thrown out by Nile mouths. An Egyptian townlet, Rhacotis, already stood on the shore and was a resort of fishermen and pirates. Alexander occupied Pharos, and had a walled city marked out by Deinocrates on the mainland to include Rhacotis. A few months later he left Egypt for the East and never returned to his city; but his corpse was ultimately entombed there. His viceroy, Cleomenes, continued the creation of Alexandria. The Heptastadium, however, and the mainland quarters seem to have been mainly Ptolemaic work. Inheriting the trade of ruined Tyre and becoming the centre of the new commerce between Europe and the Arabian and Indian East, the city grew in less than a century to be larger than Carthage; and for some centuries more it had to acknowledge no superior but Rome. It was a centre not only of Hellenism but of Semitism, and the greatest Jewish city in the world. There the Septuagint was produced. The early Ptolemies kept it in order and fostered the development of its museum into the leading Greek university; and as a free Greek city, it retained its own senate into Roman times. In 80 B.C., however, it passed formally under Roman jurisdiction according to the will of Ptolemy Alexander; though it had been under Roman influence for more than a hundred years previously. There Julius Caesar dallied with Cleopatra in 47 B.C. and was mobbed by the rabble; there his example was followed by Antony, for whose favour the city paid dear to Octavian, who placed over it a prefect from the imperial household. Alexandria seems from this time to have regained its old prosperity, commanding, as it did, an important granary of Rome; in the Augustan age, its free population was estimated at 300,000 in addition to an immense number of slaves. In A.D. 215 the emperor Caracalla visited the city; and, in order to repay some insulting satires that the inhabitants had made upon him, a general massacre was perpetrated. Notwithstanding this terrible disaster, Alexandria soon recovered its former splendour, and for some time longer was esteemed the first city of the world after Rome, while it now acquired fresh importance as a centre of Christian theology and church government. There Arianism was formulated and there Athanasius, the great opponent of both heresy and pagan reaction, worked and triumphed. As native influences, however, began to reassert themselves in the Nile valley, Alexandria gradually became an alien city, more and more detached from Egypt; and, losing much of its commerce as the peace of the empire broke up during the 3rd century A.D., it declined fast in population and splendour. In 616 it was taken by Chosroes, king of Persia; and in 640 by the Arabians, under 'Amr, after a siege that lasted 14 months, during which Heraclius, the emperor of Constantinople, did not send a single ship to its assistance. Notwithstanding the losses that the city had sustained, 'Amr was able to write to his master, the caliph Omar, that he had taken a city containing "4,000 palaces, 4,000 baths, 12,000 dealers in fresh oil, 12,000 gardeners, 40,000 Jews who pay tribute, 400 theatres or places of amusement." The well-known tale of how the famous library was used for six months to supply the furnaces of the public baths is now regarded as doubtful, in view of the many calamities which the collection had already suffered. About the year 646 'Amr was deprived of his government by the caliph Othman. The Egyptians, by whom 'Amr was greatly beloved, were so much dissatisfied by this act, and even showed such a tendency to revolt, that the Greek emperor determined to make an effort to reduce Alexandria. The attempt proved perfectly successful. The caliph, perceiving his mistake, immediately restored 'Amr, who, on his arrival in Egypt, drove the Greeks within the walls of Alexandria, captured the city after a most obstinate resistance, and completely demolished its fortifications. Alexandria now rapidly declined in importance. The building of Cairo in 969, and, above all, the discovery of the route to the East by the Cape of Good Hope in 1498, nearly ruined its commerce; the canal, which supplied it with Nile water, became blocked; and although it remained a principal Egyptian port, it played no great part in history until Napoleon's Egyptian expedition thrust it into prominence.

Battle of 1801.—The French troops stormed the city on July 2, 1798, and it remained in their hands until the arrival of the British

expedition of 1801. The battle of Alexandria, fought on March 21, of that year, between the French army under Gen. Menou and the British expeditionary corps under Sir Ralph Abercromby, took place near the ruins of Nicopolis, on the narrow spit of land between the sea and Lake Aboukir. The British position on the night of the 20th extended across the isthmus, the right resting upon the ruins of Nicopolis and the sea, the left on the lake of Aboukir and the Alexandria canal. The line faced generally southwest towards the city, the reserve division under Maj.-Gen. (Sir) John Moore on the right, the Guards brigade in the centre, and three other brigades on the left. The French attacked before dawn. The first shock was repulsed, but a French column penetrated in the dark between two regiments of the British and a confused fight ensued in the ruins, in which the 42nd (Black Watch) captured a colour. The front and rear ranks of the 28th (Gloucestershires) were simultaneously engaged, and the conduct of the regiment won for it the distinction of wearing badges both at the front and at the back of their head-dress. Other regiments which assisted in the overthrow of the French column were the 23rd, 40th and 58th. In a second attack Sir Ralph Abercromby was engaged in personal conflict with some French dragoons, and about this time received a mortal wound, though he remained on the field and in command to the end. The attack on the centre was repulsed by the cool and steady fire of the Guards, and the left wing maintained its position with ease, but the French cavalry for the second time came to close quarters with the reserve. About half-past eight the combat began to wane, and the last shots were fired at ten. The forces engaged were approximately 14,000 British to about 20,000 French, and the losses were:—British, 1,468 killed, wounded and missing, including Abercromby (who died on the 28th), Moore and three other generals wounded; French, 1,160 killed and (?) 3,000 wounded. The British subsequently advanced upon Alexandria, which surrendered on Aug. 31.

In the 19th Century.—By this time it had sunk to a small town of about 4,000 inhabitants; and it owed its modern renaissance solely to Mehemet Ali, who wanted a deep port and naval station for his viceregal domain. He restored its water communication with the Nile by making the Mahmudiya canal, finished in 1820; and he established at Ras et-Tin his favourite residence. The old Eunostus harbour became the port, and a flourishing city arose on the old Pharos island and the Heptastadium district, with outlying suburbs and villa residences along the coast eastwards and the Mareotic shore. Being the starting-point of the "overland route" to India, and the residence of the chief foreign consuls, it quickly acquired a European character. At Alexandria most of the negotiations between the powers and Mehemet Ali were conducted; thence started the Egyptian naval expeditions to Crete, the Morea and Syria; and thither sailed the betrayed Ottoman fleet in 1839. It was twice threatened by hostile fleets, the Greek in 1827 and the combined British, French and Russian squadrons in 1828. It was connected with Cairo by railway in 1856, and remained the real capital of Egypt till Said Pasha died there in 1863 and Ismail came into power. Though this prince continued to develop the city, giving it a municipality in 1866 and new (but inadequate) harbour works in 1871–78, he developed Cairo still more; and the centre of gravity definitely shifted to the inland capital.

Bombardment of 1882.—Fate, however, again brought Alexandria to the front. After a mutiny of soldiers there in 1881, the town was greatly excited by the arrival of an Anglo-French fleet in May 1882, and on June 11 a terrible riot and massacre took place, resulting in the death of a large number of Europeans. Since satisfaction was not given for this and the forts were being strengthened at the instigation of Arabi Pasha, the British admiral, Sir Beauchamp Seymour (afterwards Lord Alcester), sent an ultimatum on July 10 and demolished the forts the next day. As Arabi did not submit, a British military expedition landed at Alexandria on Aug. 10, the sequel being the British occupation of the whole country.

IV. Antiquities.—Persistent efforts have been made to explore the antiquities of Alexandria. The authorities of the museum have been enabled from time to time to carry out systematic

excavations when opportunity offered; D. G. Hogarth made tentative researches on behalf of the Egyptian Exploration Fund and the Society for the Promotion of Hellenic Studies in 1895; and a German expedition worked for two years (1898-99). But the great and growing modern city stands right over the ancient one, making it almost impossible to find any considerable space in which to dig, except at enormous cost; and the general subsidence of the coast has sunk the lower-lying parts of the ancient town under water. Unfortunately the spaces still most open are the low grounds to north-east and south-west, where it is practically impossible to get below the Roman strata.

The most important results were those achieved by Dr. G. Botti, late director of the museum, in the neighbourhood of "Pompey's Pillar," where there is a good deal of open ground. Here substructures of a large building or group of buildings have been exposed, which are perhaps part of the Serapeum. Hard by immense catacombs and columbaria have been opened which may have been appendages of the temple. These contain one very remarkable vault with curious painted reliefs, now lighted by electricity and shown to visitors. The objects found in these researches are in the museum, the most notable being a great basalt bull, probably once an object of cult in the Serapeum. Other catacombs and tombs have been opened in Kom es-Shugafa Hadra (Roman) and Ras et-Tin (painted). The Germans found remains of a Ptolemaic colonnade and streets in the north-east of the city, but little else. Hogarth explored part of an immense brick structure under the mound of Kom ed-Dik, which may have been part of the Paneum, the Mausolea or a Roman fortress. The making of the new foreshore led to the dredging up of remains of the Patriarchal church; and the foundations of modern buildings are seldom laid without some objects of antiquity being discovered. The wealth underground is doubtless immense; but, despite all efforts, there is not much for antiquarians to see in Alexandria outside the museum and the neighbourhood of "Pompey's Pillar."

ALEXANDRIA, town in Bonhill parish, Dumbartonshire, Scotland, on the right bank of the Leven, about 3m. N. of Dumbarton, served by the L.N.E.R. and L.M.S.R. It owes its origin almost entirely to cotton printing and bleaching works based on an abundant supply of excellent water and contains a large Turkey-red dyeing establishment. Pop. (1921) 5,600. Alexandria is connected with Bonhill, on the opposite bank of the river, by a bridge which replaced in 1898 one bought three years earlier by the county council from the Smollett family, who have been closely associated with the district since the time of Sir James Smollett, the novelist's grandfather. Alexandria takes the name from a member of this family, Alexander Smollett. The industries of Bonhill are calico printing, dyeing and bleaching. Pop. (1921) of parish 10,359. Jamestown, about 1m. N.E. of Alexandria, with a station on the L. and N.E. railway, contains some of the largest cotton printing works in Scotland. Pop. of parish (1921) 2,389.

ALEXANDRIA, a city of Louisiana, U.S.A., on the south bank of the Red river, in the centre of the state; the capital of Rapides parish. It is on Federal highways 71 and 165, and is served by the Louisiana Railway and Navigation Company, the Texas and Pacific, the Rock Island, the Missouri Pacific, the Southern Pacific and the Louisiana and Arkansas railways, and by steamboats on the river. The population in 1920 was 17,510, (45% were negroes), and 23,025 in 1930.

The city is on a level plain in the centre of extensive forests of long-leaf pine, interspersed with various hard woods. Rice, cotton, sugar, alfalfa and vegetables are the principal crops raised in the vicinity. There are over 100 factories in and near the city, with an aggregate output valued at \$15,000,000, including saw-mills, a creosoting plant, foundries and machine shops, cottonseed-oil mills, brick yards, an oil refinery, broom-handle and talcum factories and railroad repair shops. The city has a large wholesale and retail trade. A free traffic bridge leads to the town of Pineville, on the north side of the river (pop. 1920, 2,188), where there is a national cemetery. A state hospital for the insane, and Louisiana college, a Baptist co-educational institution which was

opened in 1906, Camp Beauregard (8,000 ac.), a U.S. Veterans' hospital, the State Industrial School for girls and the State Colony for the feeble-minded are also near by.

Alexandria was named after Alexander Fulton, on whose grant from Spain the first settlement was made in 1785. It was incorporated as a town in 1818 and received a city charter in 1882. In May 1863 and again in March 1864, it was occupied by Union forces under Admiral David D. Porter and Gen. N. P. Banks. When finally vacated, May 12-13, 1864, the city was almost entirely burned. The Union gunboats, which had passed up the river toward Shreveport at high tide, were caught above the falls at Alexandria, and saved by a splendid piece of engineering (a dam at the falls) by Lieut.-Col. Joseph Bailey (1827-67).

ALEXANDRIA, a city and a port of entry in Northern Virginia, U.S.A., on the W. bank of the Potomac river, 7m. below Washington, D.C.; contiguous to, but independent of, Arlington county. It is served by the Richmond, Fredericksburg and Potomac, the Southern, and the Old Dominion railways, and by the Norfolk and Washington, D.C., Steamboat Company. Through the Potomac yards for the classification of freight, on the northern boundary of the city, there is a daily movement of over 3,000 cars. The river is a mile wide at this point, with a good harbour. The population was 18,060 in 1920; of whom 4,112 were negroes; and 24,149 in 1930.

Alexandria is a quaint, old-fashioned city, with quiet, shady streets. Many buildings date back to the 18th century: Christ church (1783-88), in which George Washington and Robert E. Lee worshipped; Carlyle house (1752), where General Braddock in 1755 organized his ill-fated expedition against Fort Duquesne, and where, later in the same year, the famous Council of Governors met to determine upon concerted action against the French; City hotel; Washington Free school (1785); Friendship Engine house (1774); the home of "Light Horse Harry" Lee, and his son, Robert E. Lee; Marshall house, where the first fatality of the Civil War took place; and others of historic interest. An imposing modern land-mark, visible for many miles, is the George Washington National Masonic memorial, recently built at a cost of \$5,000,000. About 2½m. west of Alexandria is the Protestant Episcopal Theological seminary, opened in 1823.

BY COURTESY OF REVIEW OF REVIEWS COMPANY

OLD CHRIST CHURCH AT ALEXANDRIA, VA., IN WHICH GEORGE WASHINGTON SERVED AS ONE OF THE FIRST VESTRYMEN AND WHERE ROBERT E. LEE WORSHIPPED

Alexandria is a distributing and jobbing centre for the northern counties of Virginia. There is a United States Naval Torpedo station on the water-front and a large plant for the construction and repair of refrigerator-cars is near the city. There are about 60 other industrial plants. Their principal products are glass, clothing, silk, spark plugs, beverages, ice and fertilizers. The municipality owns its gas plant, but the water supply is under private control. The daily newspaper, the *Alexandria Gazette*, was founded in 1784.

The first settlement here was made in 1695. In 1749 a town was laid out, called Belle Haven, or Belhaven. A few years

later the name was changed to Alexandria, in honour of John Alexander, who had owned the land in the latter part of the 17th century. The city soon became an important port for the products of Northern Virginia, from which flour and tobacco were shipped to the West Indies and even to Europe. Improved roads were built for wagon-trains, and "rolling roads" were constructed, on which hogsheads of tobacco were rolled down from the plantations to the port. This economic development was checked by the anomalous political history of the city. From 1790 to 1846 it was part of the District of Columbia, at first with a vague and uncertain status, and later overshadowed by the development of the capital. Hardly had it been ceded back to Virginia before the clouds of the Civil War began to gather, and during the whole course of the war it was occupied by Union troops. After the erection of the State of West Virginia (1863), and until the close of the war, it was the seat of the "Alexandria Government" (see VIRGINIA). In 1814 the city was threatened by a British fleet, but averted attack by a payment of about \$100,000. Alexandria was incorporated in 1779 and rechartered in 1852. A commission-manager form of government was adopted Sept. 1, 1922.

ALEXANDRIAN SCHOOL, a term applied to certain tendencies in literature, science and art, which took their rise in Alexandria. That city, founded by Alexander the Great, was in every way admirably adapted for becoming the new centre of the world's activity and thought. Its situation brought it into commercial relations with all the nations lying around the Mediterranean, and at the same time rendered it the one communicating link with the wealth and civilization of the East. The great natural advantages it thus enjoyed were increased to an enormous extent by the care of the sovereigns of Egypt, the Ptolemies Soter (323-285), Philadelphus (285-247) and Euergetes (247-222). The first began to draw around him from various parts of Greece a circle of men eminent in literature and philosophy. To these he gave every facility for the prosecution of their learned researches. Under the inspiration of his friend Demetrius of Phalerum, the Athenian orator, statesman and philosopher, this Ptolemy laid the foundations of the great Alexandrian library. He also built, for the convenience of his men of letters, the museum, which was in many respects not unlike a modern university. Philadelphus, whose librarian was the poet Callimachus, bought up all of Aristotle's library, and included in his collection some foreign works, among these was the Pentateuch, the Greek translation of which (the Septuagint) dates from his time. Euergetes largely increased the library by getting possession of the official Athenian copies of the dramatists, and by compelling all travellers who arrived in Alexandria to leave a copy of any work they possessed.

The intellectual movement so originated extended over a long period of years, 306 B.C.-A.D. 642 which falls into two divisions; 306-30 B.C. from the foundation of the Ptolemaic dynasty to its final subjugation by the Romans; and 30 B.C. to A.D. 642 when Alexandria was destroyed by the Arabs. In the first of the two periods the intellectual activity was of a purely literary and scientific nature. This was particularly noticeable under the early Ptolemies, Alexandria being then almost the only home in the world for pure literature. During the last century and a half before the Christian era, the school, as it might be called, began to break up and to lose its individuality. This was due partly to the state of government under some of the later Ptolemies, partly to the formation of new literary circles in Rhodes, Syria and elsewhere, whose supporters, though retaining the Alexandrian peculiarities, could scarcely be included in the Alexandrian school. Under Roman sway the influence of the school was extended over the whole known world, but men of letters began to concentrate at Rome rather than at Alexandria. Meanwhile, Alexandria developed a new movement, which was not in the old direction—having, indeed, nothing in common with it. With its character largely determined by Oriental gnosticism and containing Jewish and later, Christian elements, this second Alexandrian school resulted in the speculative philosophy of the Neoplatonists and the religious philosophy of the Gnostics and early church fathers.

Thus we may distinguish an earlier Alexandrian school, which is

scientific and literary, and a later, which is philosophic and theological. In both, "school" is used rather loosely; we should perhaps do better to speak of "tendency."

I. Literature.—The general character of the literature of the school appears as the necessary consequence of the state of affairs brought about by the fall of Greek nationality and independence. The great works of the Greek mind had formerly been the products of the free and active, yet not undisciplined atmosphere of the Greek city-state. But with the rise of Macedonia, the city-state vanished from practical politics, taking with it freedom as a Greek understood it, and in large measure, independence and originality of thought. A substitute for this originality was found by the Alexandrians in learned research, stimulated by a reverential interest in the works of the past (cf. CLASSICS). They studied criticism, grammar, prosody and metre, antiquities and mythology. The results of this study constantly appear in their productions. Their works are written by and for the learned; they appeal to a small public, little interested in political and military affairs of the time, courtly, as was natural, seeing that many were under the direct patronage of a king, full of literary and scientific interests of all kinds, but, as it happened, not including any writer of first-rate genius. Three tendencies are very marked; viz., (1) Interest in all branches of science, and in the statement of its results in literary form. (2) Interest in the technique of literary expression, particularly that of verse; prose was for some reason far less popular. (3) Preoccupation in what was then a comparatively new literary motif, since it dates only from Euripides, namely the psychology of love. Most of the great love stories date from this period, and almost for the first time, the heroine is apt to be the central figure. The chief literary forms were:—

(1) *Epic*.—This, against the advice and practice of the greatest literary authority, Callimachus, was attempted by several writers. The *Argonautica* of Apollonius Rhodius survives; it is a very learned work, showing immense knowledge of epic metre and diction, and many episodes (notably the central one, the loves of Jason and Medea) are full of merit; but as a whole, it is dull and lacks unity. Epic was also written by Rhianus, who produced a long poem, now lost, on the Messenian wars. Better and more characteristic was the *epyllion*, or little epic, in which some one episode was treated at length, the rest of the story being merely alluded to. Good examples are the two poems on Heracles and on the Dioscuri, in the Theocritean corpus; the most famous was the *Hecale* of Callimachus, of which fragments survive.

(2) *Didactic poetry*.—This was very popular, for it gave an opportunity to handle neatly and tastefully a subject interesting in itself. Prominent examples are the *Phaenomena* of Aratus, a versified handbook of astronomy and meteorology; the *Theriaca* of Nicander, on snake-bites and herbal remedies for them, is remarkable for its highly learned and obscure diction, a fault, or rather a deliberate affectation, of many Alexandrians. Many mythological poems, as the *Aetia* of Callimachus, approach didactic poetry in subject, since they profess to explain customs, rites and so forth.

(3) *Elegiac poems* were of many kinds. Most characteristic were those dealing with love; in this genre, which was not strictly new, since it had been handled long before by Mimnermus, for instance, the Alexandrians, with their new interest in psychology and *ethos*, excelled, to judge from the scanty fragments remaining, and the criticisms and imitations of Latin writers such as Propertius. The *Lyde* of Antimachus was the pioneer of this movement; the first Alexandrian writer of the erotic elegy was Philetas of Cos; Callimachus, Hermesianax, and others also won distinction therein. The elegy was also used for mythological narrative, sometimes lengthy, as in Callimachus' *Aetia*; the mythological works of Euphron, however, seem to have been mostly in hexameters. As an important offshoot of these compositions, we may notice the epigram (cf. ANTHOLOGY) which assumed a new importance among the Alexandrians.

(4) *Closest-drama*, including both tragedies and comedies. As the great age of drama was over, nothing first-rate was to be expected from the Pleiad, as the seven most admired authors in

this vein were called. The fragments which survive, and the Alexandra of Lycophron (in form a *rhesis* or messenger's speech from a tragedy, and a byword for its extreme obscurity) do not whet our appetite for more.

(5) *The mime*, a short dialogue, or monologue dealing with everyday life. Besides anonymous fragments, we have several mimes of Herodas, a writer little appreciated in antiquity. They are artificial in language, for they are in the dialect and metre of the old Ionian writers of iambics; in content, they show keen and cynical observation of commonplace, and not always very reputable, men and women. A development of this kind of work, and of the earlier prose mimes of Sophron, was the pastoral, usually a dialogue in form, sketching, with or without idealization, country life, especially that of herdsmen. The great name here is that of Theocritus, among whose *Eidyllia* ("little scenes or pictures") are some of the most beautiful poems in any language. Several of his imitators, such as Bion, Moschus, and the unknown writer of the Eighth Idyll, are decidedly pretty, although artificial.

(6) *Prose*: here the characteristic form is rhetorical history, or at least history written with an eye to stylistic effect, although research was not absent. Timaeus and Theopompus (both lost) were among the most celebrated; Cleitarchus and others wrote on the exploits of Alexander, which became in their hands more and more mixed with sheer fable. Polybius' history is in large measure a counterblast to the rhetorical style; it remained an almost isolated attempt.

(7) *Lyric poetry* was but mediocre, for it was not an age of intense emotions freely expressed. However, numerous pieces were written in lyric metres, avoiding the great complication and variety of Pindar and his contemporaries and keeping to those forms of verse which are easily reducible to fixed rules. Here Sotades may be mentioned. He wrote a number of poems in a variety of Ionics called after him Sotadean; the subjects appear to have been highly indecent.

(8) *Parody and satire* flourished, for example the *Silloi* of Timon, mock epic verses abusing philosophers.

In *grammar and philology*, the work of the Alexandrian critics, although lacking the minute accuracy of the best modern scholarship, aided as that is by palaeography, comparative philology, and archaeology, was most meritorious. It was their aim to collect and preserve in a correct and intelligible form the literature of Greece, and to comment adequately on it, where necessary. Their methods (*διόρθωσις*, textual or lower criticism, with *ἀνέγνωσις*, correct accentuation; *τέχνη* or syntactical study, *ἐξηγήσις* or commentary, and *κρίσις* higher or literary criticism, differ little in principle from our own. (See CLASSICS; TEXTUAL CRITICISM.) Besides the great Aristarchus, and Zenodotus, whose labours on Homer were second only to Aristarchus' in value, may be named Aristophanes of Byzantium, Homeric critic and inventor of the signs for accents; Crates; and several of the most famous writers, as Apollonius Rhodius, Lycophron, and Callimachus. Many works were written on grammar (as by Dionysius Thrax, the first important Greek grammarian), chronology (Eratosthenes is the great name here, see CHRONOLOGY); (Callimachus wrote on the chronology of the drama), mythology (the *Bibliotheca* falsely ascribed to Apollodorus, and many scholia, epitomize much of this learning), geography (again Eratosthenes took a leading part), and astronomy (Hipparchus, and later Claudius Ptolemaeus, from whom the Ptolemaic system is named; see ASTRONOMY). Medicine was studied with much success (Herophilus and Erasistratus were great anatomists), and finally, the mathematicians of that age notably advanced this science; Archimedes and Apollonius of Perga are especially great names (see MATHEMATICS) while Euclides is still familiar as the "Euclid" but recently displaced as a text-book of geometry.

BIBLIOGRAPHY.—Christ-Schmidt, *Geschichte der griechischen Literatur*; Sandys, *History of Scholarship*, v.i; Couat, *La Poésie alexandrine*; Susemihl, *Geschichte der griechischen Literatur in der Alexandrinerzeit*. Nicolai's *Griechische Literaturgeschichte*, though somewhat out of date, is useful for bibliography.

II. Philosophy.—The mutual criticisms of the various philosophic schools, all of which continued to exist, had resulted in a general feeling of uncertainty and scepticism. As a result, any doc-

trine which claimed infallible certainty was sure of a hearing; and this was found in the various Eastern religions, notably Judaism. Hence arose that characteristic feature of Alexandrian thought which we may call *gnosticism*. A supposed revelation (*gnosis*) personal or derived from ancient writings, set forth with Greek logic and rhetoric, is the central feature of all the most characteristic Alexandrian philosophy (see NEO-PYTHAGOREANISM; HERMES TRISMEGISTUS).

So far as the Jewish succession is concerned, the great name is that of Philo in the first century of our era. He took Greek metaphysical theories, and, by the allegorical method, read them into the Old Testament. He dealt with (a) human life as explained by the relative nature of Man and God, (b) the Divine nature and the existence of God, and (c) the great *Logos* doctrine as the explanation of the relation between God and the material universe. From these three arguments he developed an elaborate theosophy which was a syncretism of oriental mysticism and pure Greek metaphysics, and may be regarded as representing the climax of Jewish philosophy. Of pagan schools of philosophy, the first was Neo-Pythagoreanism, the second and last Neo-Platonism (*q.v.*). Their doctrines were a synthesis of Platonism, Stoicism and the later Aristotelianism with a leaven of oriental mysticism which gradually became more and more important. The world to which they spoke had begun to demand a doctrine of salvation to satisfy the human soul. They therefore devoted themselves to examining the nature of the soul, and taught that its freedom consists in communion with God, to be achieved by absorption in a sort of ecstatic trance. This doctrine reaches its height in Plotinus, after whom it degenerated into magic and theurgy in its unsuccessful combat with the victorious Christianity. Finally this pagan theosophy was driven from Alexandria back to Athens under Plutarch and Proclus, and occupied itself largely in purely historical work based mainly on the attempt to reorganize ancient philosophy in conformity with the system of Plotinus. This school ended under Damascius when Justinian closed the Athenian schools (A.D. 529). The influence of all this on some of the most enlightened Christians, as Clement and Origen, was enormous. They strove after a Christian *gnosis*. Side by side with them, a swarm of semi-Christian Gnostic sects arose. Such ideas are still present much later in Synesius, bishop of Ptolemais, and Neo-Platonism, gradually absorbed into Christianity, profoundly and lastingly modified its theology.

See *Histories of Philosophy* by Zeller, Ueberweg, Windelband, etc., and bibliography of CHURCH HISTORY and the other special articles referred to above.

ALEXANDRIA TROAS, an ancient Greek city of the Troad, situated on the west coast at nearly its middle point, a little south of Tenedos. It was built by Antigonos, perhaps about 310 B.C., and was called by him Antigonía Troas. Early in the next century the name was changed by Lysimachus to Alexandria Troas, in honour of Alexander's memory. As the chief port of north-west Asia Minor, the place prospered greatly in Roman times, and the existing remains sufficiently attest its former importance. Thence St. Paul sailed for Europe for the first time, and there occurred later the episode of the raising of Eutychus (Acts xx. 5-12). The circuit of the old walls can be traced, and there are remains of some ancient buildings, including a bath and gymnasium and an aqueduct built by Trajan. The harbour had two large basins, now almost choked with sand.

ALEXANDRINA, LAKE, in South Australia, forms with Lake Albert and the curious boomerang-shaped Coorong a series of extensive and shallow lagoons about the outlet of the River Murray. (Lake Alexandrina: area, c. 220 sq.m.; depth: 7-10 ft.; L. Albert: c. 64 sq.m.; 3-6 ft.) A relic of a sea-gulf—analogue to Spencer and St. Vincent gulfs—which penetrated northwards into what is now the lower Murray basin, Lake Alexandrina was formed by a (geologically) recent elevation of the coast line, so that now the Murray, lacking a "mouth" in the ordinary sense, can only be approached by an entrance over a shifting sand-bar carrying some 7-12 ft. of water and beset with breakers. Moreover the large water-surface which these lakes expose, coupled with a sub-arid climate (average annual temp. c. 61-62°; average annual rainfall c. 22 in.) leads to an evaporation which has been esti-

mated at 42,000 million cu.ft. per annum (Lakes Alexandrina and Albert). This loss, which has normally to be borne by the River Murray system, is particularly felt in dry seasons. An intake of sea-water may then occur and adversely affect pastoral and agricultural interests for some distance upstream. Associated with certain incidents in the history of Australian exploration—notably that of Sturt's voyage of discovery down the Murrumbidgee-Murray in 1830—Lake Alexandrina is now chiefly of interest as constituting one of Australia's national problems. The River Murray valley is of rapidly growing importance. Lack of a natural outlet by way of the mouth has encouraged, if it has not caused, the development of numerous railway lines which tap the river at various points along its course. The riparian States, and particularly the capitals of those States, have vested interests which militate against the construction of a river-mouth port. This project, however, is appealing ever more insistently as one of national importance. Various solutions—notably a port at Goolwa served by a connecting canal—have been proposed. After being referred to various commissions and expert investigations, the question was discussed by Sir George Buchanan (Report on Transport in Australia, vol. ii., 1927), and the matter was explicitly referred to by the Commonwealth Premier in a speech which was held by some to foreshadow action by the Commonwealth Government. Subsequently, the draining of Lake Albert was proposed, and the conversion of its bed into agricultural land.

ALEXANDRINE VERSE, a name given to the leading measure in French poetry. It is the heroic French verse, used in epic narrative, in tragedy, and in the higher comedy. There is some doubt as to the origin of the name; but most probably it is derived from a collection of romances, compiled in the 12th century, of which Alexander of Macedon was the hero. Before the publication of this work most of the *trouvère* romances appeared in octosyllabic verse. There is also a theory that the form was invented by a poet named Alexandre. The new work, which was henceforth to set the fashion to French literature, was written in lines of 12 syllables, but with a freedom of pause which was afterwards greatly curtailed. The new fashion, however, was not adopted all at once. The metre fell into disuse until the reign of Francis I., when it was revived by Jean Antoine de Baif (1532-89), one of the seven poets known as the *Pléiade* (*q.v.*). Jodelle (1532-73) mingled episodic Alexandrines with the *vers communs* of his tragedies and so introduced them into drama. It was Ronsard, however, who made the verse popular and gave it vogue in France. From his time it became the recognized vehicle for all great poetry, and the regulation of its pauses became more strict. Two laws came to be established with regard to the pauses. The first is, that each line should be divided into two equal parts, the sixth syllable always ending with a word. In the earlier use of this metre, on the contrary, it frequently happened that the sixth and seventh syllables belonged to the same word. The other is that, except under the most stringent conditions, there should be none of what the French critics call *enjambement*, that is, the overlapping of the sense from one line on to the next. Ronsard completely ignored this rule, which was after his time settled by the authority of Malherbe. Later French poets have abandoned the rigidity of Malherbe, as a reference to a popular play like Rostand's *Cyrano de Bergerac* will show.

Michael Drayton, who was 22 years of age when Ronsard died, seemed to think that the Alexandrine might be as pleasing to English as it was to French ears, and in this metre he wrote a long poem called the *Polyolbion*. The metre, however, failed to catch the English ear. In English heroic verse it is but rarely introduced; but in the favourite narrative metre, known as the Spenserian, it comes in regularly as the concluding line of each stanza. In English usage, moreover, there is no fixed rule as to the position of the pause. Thus Thomson (*Castle of Indolence*, i. 42):—

And music lent new gladness to the morning air.

The danger in the use of the Alexandrine is that, in attempting to give dignity to his line, the poet may only produce heaviness, incurring the criticism of Pope:—

A needless Alexandrine ends the song,
That, like a wounded snake, drags its slow length along.

The Alexandrine was the dominant metre in Dutch poetry from the 16th to the middle of the 19th century, and about the time of its introduction to Holland it was accepted in Germany by the school of Opitz. In the course of the 17th century, after being used without rhyme by Seckendorf and others, it formed a transitional station on the route to German blank verse, and has since then been rarely employed, except occasionally in rhymed comedy.

ALEXANDRISTS, the name given to those philosophers of the Renaissance, who, in the great controversy on the subject of personal immortality, adopted the explanation of the *De Anima* given by Alexander of Aphrodisias. According to the orthodox Thomism of the Roman Catholic Church, Aristotle rightly regarded reason as a faculty of the individual soul. Against this, the Averroists, led by Agostino Nifo (*q.v.*), introduced the modifying theory that universal reason in a sense individualizes itself in each soul and then absorbs the active reason into itself again. These two theories respectively evolved the doctrine of individual and universal immortality, or the absorption of the individual into the eternal One. The Alexandrists, led by Pietro Pomponazzi, boldly assailed these beliefs and denied that either was rightly attributed to Aristotle. They held that Aristotle considered the soul as a material and therefore a mortal entity which operates during life only under the authority of universal reason. Hence the Alexandrists denied the possibility of immortality in every shape or form. Since the soul is organically connected with the body, the dissolution of the latter involves the extinction of the former.

ALEXANDRITE, a variety of chrysoberyl (*q.v.*) discovered in the Urals in 1833, on the day set apart for celebrating the majority of the Russian *cesarevich*, afterwards the tsar, Alexander II., in whose honour the stone was named. It is remarkable for being strongly dichroic, that is, exhibiting different colours according as viewed from different directions, generally appearing dark green by daylight and raspberry-red by candle-light, or by daylight transmitted through the stone. As red and green were the military colours of Russia, the mineral became highly popular as a gem-stone.

ALEXANDROV, TODOR (1882-1924), Macedonian leader, was born at Stip in Central Macedonia. As a youth he took part in the *comitadji* campaign against Turkey, becoming one of the most prominent leaders of the Bulgarian bands in Macedonia. After the treaties which concluded the World War had allotted his native district to Yugoslavia, he came to Sofia and began to reorganize the old I.M.R.O. (International Macedonian Revolutionary Organization) against Yugoslavia and Greece. Imprisoned by Stamboliski, he escaped through the connivance of his friends, retired to the mountains near Petritch, and there organized a power which was able not only to terrorize Serbian and Greek Macedonia, but also to defy the Bulgarian Government, against which he declared irrevocable hostility in 1923, after he had failed to persuade Stamboliski to support his cause. Alexandrov himself aimed at an autonomous Macedonia, with its capital at Salonika, and thus incurred the hostility of the more moderate group of "Federalists," who were on tolerable relations with the Yugoslav Government. He helped to bring about the fall and death of Stamboliski in June 1923, and under the Government of Tsankov was practically an independent ruler; but when this Government also disavowed the Macedonians, Alexandrov turned elsewhere for help, and entered into relations, first with Turkey, then with M. Radič, the Croat leader, and finally with the Third International. A treaty concluded in the summer of 1924 between the Macedonian Autonomists and the Third International was alleged to bear Alexandrov's signature, but afterwards repudiated by him. Violent dissensions broke out in his party over the advisability or not of accepting Russian help, and as a result of them, Alexandrov was murdered on Aug. 31, 1924.

Alexandrov was for years the uncrowned and absolute king of the Bulgarian Macedonians, who almost worshipped him. He was a very fine figure, tall, black-bearded and handsome, and as ruthless as he was brave. His courts knew only three verdicts: acquittal, a hundred stripes, or death, the last being inflicted for theft, insult to a woman, or political treachery. He must have

been responsible for many hundreds of deaths; withal, he was a man of personal probity and fanatical and selfless patriotism.

(C. A. M.)

ALEXANDROVSK, a town in Sakhalin Island in the far eastern area of the R.S.F.S.R. Lat. $51^{\circ} 10'$ N. Long. $142^{\circ} 5'$ E. Pop. (1926) 7,807. It is a port on the west coast in the coal and naphtha area and is the administrative centre for the Russian part of the island.

ALEXANDROVSK, a town in South Russia, now called Zaporozhe (*q.v.*).

ALEXEYEV, MIKHAIL (1857–1918), Russian soldier, was born Nov. 3, 1857. Entering the army in 1876, he became a general in 1904. At the outbreak of the World War he was appointed chief of staff on the south-western front, and in that capacity was largely responsible for the Russian victory in Galicia in 1914. In March 1915 he took over command of the armies on the north-western front and by his energy and ability saved them from complete destruction. Appointed chief of the general staff in Aug. 1915, he had to give up this office in Nov. 1916 on account of ill health.

From March to May 1917 he commanded the army; recalled in September by Kerensky, he attempted to mediate between Kerensky and Kornilov. Failing in this, he went to S. Russia and there organized the "Volunteer" army. On the death of Kornilov in March 1918, the military command of the army was taken over by Denikin and Alexeyev became leader of the Government. On Sept. 25, 1918 he died of heart disease at Ekaterinodar.

ALEXIS, Greek comic poet of the Middle Comedy, was born at Thurii and taken early to Athens, where he became a citizen. He wrote during the latter half of the 4th century and perhaps the early part of the 5th. Plutarch says that he lived to the age of 106, and that he died on the stage while being crowned. According to Suidas, who calls him Menander's uncle, he wrote 245 comedies, of which about 130 titles are preserved. The fragments (about 1,000 lines) attest the wit and refinement of the author (Koch, *Comicorum Atticorum Fragmenta*).

ALEXIS, WILLIBALD, the pseudonym of GEORG WILHELM HEINRICH HÄRING (1798–1871), German historical novelist. He was born June 29, 1798 at Breslau, where his father, who came of a French refugee family, named Hareng, was an official. He attended the Werdersche Gymnasium in Berlin, and served as a volunteer in the campaign of 1815. On his return he studied law at the universities of Berlin and Breslau. Settling in Berlin, he edited, 1827–35, the *Berliner Konversationsblatt*, in which for the first two years he was assisted by Friedrich Christoph Förster (1791–1868). In 1852 he retired to Arnstadt in Thuringia, where after many years of broken health he died Dec. 16, 1871.

Alexis made his name as a writer by an idyll in hexameters, *Die Treibjagd* (1820), and several short stories in which the influence of Tieck is observable; but his reputation was first established by two historical romances, *Walladmor* (1823), and *Schloss Avalon* (1827), which, published as being "freely translated from the English of Sir Walter Scott, with a preface by Willibald Alexis," so closely imitated the style of the famous Scotsman as really to deceive even Scott's admirers. Alexis published a number of successful short stories (*Gesammelte Novellen*, 1830–31), some books of travel, and the novels *Das Haus Dusterweg* (1835) and *Zwölf Nächte* (1838).

In *Cabanis* (1832), a story of the time of Frederick the Great, he entered the field of patriotic-historical romance, in which he earned the name of "der Maerkische Walter Scott" (Walter Scott of the Mark). *Cabanis* is written in the first person, is rather clumsy in construction, and has the faults of excessive romanticism. From 1840 onwards he published at short intervals a series of romances, each dealing with some epoch in the history of Brandenburg. Among them may be noted *Der Roland von Berlin* (1840); *Der falsche Woldemar* (1842); *Die Hosen des Herrn von Bredow* (1846–48), in which room is found for many delightful folk and ghost stories; and *Ruhe ist die erste Bürgerpflicht* (1852). In 1842, in conjunction with the publicist Julius Eduard Hitzig (1780–1849), he began the publication of *Der neue Pitaval* (continued by A. Vollert, Leipzig, 1842–65; new edition Leipzig,

1866–91), a collection of criminal anecdotes culled from all nations and all times. This publication attained great popularity, and is to-day of psychological interest and value.

BIBLIOGRAPHY.—His *Gesammelte Werke* were published in Berlin (1874); the *Vaterländische Romane* in eight volumes (1881, 1884), and, since the expiration of the copyright in 1901, in many cheap reprints. Cf. *W. Alexis' Erinnerungen*, edited by M. Ewert (1900); and essays by Julian Schmidt, *Neue Bilder aus dem geistigen Leben unserer Zeit* (1873); G. Freytag, *Werke*, vol. xvi. and xxiii.; A. Stern, *Zur Literatur der Gegenwart* (1880); and T. Fontane, *Bayreuther Blätter*, vi. (1883).

ALEXISBAD, a spa of Anhalt, Germany, under the Harz mountains, 1,000ft. above sea-level, noted for its medicinal waters, of which the Alexisbrunnen, a ferruginous spring, is used for drinking, while the Selkebrunnen supplies the baths, which are of use in feminine disorders. The place was founded in 1810 by Duke Alexis of Anhalt-Bernburg.

ALEXIUS I. (1048–1118), emperor of the East, was the third son of John Comnenus, nephew of Isaac Comnenus, emperor 1057–59. His father declined the throne on the abdication of Isaac, who was accordingly succeeded by four emperors of other families between that date and 1081. Under one of these emperors, Romanus Diogenes (1067–71), he served with distinction against the Seljuk Turks. Under Michael Parapinaces (1071–78) and Nicephorus Botaniates (1078–81) he was also employed, along with his elder brother Isaac, against rebels in Asia Minor, Thrace and in Epirus (1071). The success of the Comneni roused the jealousy of Botaniates and his ministers, and the Comneni were almost compelled to take up arms in self-defence. Botaniates was forced to abdicate and retire to a monastery, and Isaac declined the crown in favour of his younger brother Alexius, who then became emperor in the 33rd year of his age. His long reign of nearly 37 years was full of difficulties (*see* ROMAN EMPIRE, LATER). At the very outset he had to meet the formidable attack of the Normans (Robert Guiscard and his son Bohemund), who took Dyrrhachium and Corfu, and laid siege to Larissa in Thessaly. The Norman danger ended for the time with Robert Guiscard's death (1085) and the conquests were recovered. He had next to repel the invasions of Patzinaks (Petchenegs) and Kumans in Thrace, with whom the Manichaean sects of the Paulicians and Bogomilians made common cause; and thirdly, he had to cope with the fast-growing power of the Turks in Asia Minor. Above all he had to meet the difficulties caused by the arrival of the warriors of the first crusade, which had been in a great degree initiated owing to the representations of his own ambassadors, though the help which he wanted from the West was simply mercenary forces and not the immense hosts which arrived to his consternation and embarrassment. The first part, under Peter the Hermit, he got rid of by sending them on to Asia Minor, where they were massacred by the Turks (1096). The second and much more serious host of warriors, led by Godfrey of Bouillon, he conducted also into Asia, promising to supply them with provisions in return for an oath of homage, and by their victories recovered for the empire a number of important cities and islands—Nicaea, Chios, Rhodes, Smyrna, Ephesus, Philadelphia, Sardis, and in fact most of Asia Minor (1097–99). This is ascribed as a credit to his policy and diplomacy by his daughter, by the Latin historians of the crusade to his treachery and falseness. The last 20 years of his life were marked by persecution of the followers of the Paulician and Bogomilian heresies (one of his last acts was to burn Basilus, a Bogomilian leader, with whom he had engaged in a theological controversy), by renewed struggles with the Turks (1110–17), and by anxieties as to the succession, which his wife Irene wished to alter in favour of her daughter Anne's husband, Nicephorus Bryennius, for whose benefit the special title panhypersebastos (*i.e.* as it were *augustissimus si quis alius*) was created. This intrigue disturbed even his dying hours. He deserves the credit of having raised the empire from a condition of anarchy and decay at a time when it was threatened on all sides by new dangers. No emperor devoted himself more laboriously or with a greater sense of duty to the task of ruling.

(J. B. B.)

ALEXIUS II. (COMNENUS) (1167–1183), emperor of the East, was the son of Manuel Comnenus and Maria, daughter of Raymond, prince of Antioch, and was born at Constantinople on Sept. 10, 1167. On Manuel's death, Maria, who had been immured in a convent under the name of Xene, had herself proclaimed regent (1179–80), and handing over her son to evil counsellors, who encouraged him in every vice, supported the government of Alexius the protosebastos (nephew of Manuel), who was supposed to be her lover. The young Alexius and his friends now tried to form a party against the empress mother and the protosebastos; and his sister Maria, wife of Caesar John, stirred up riots in the streets of the capital. Their party was defeated (May 2, 1182), but Andronicus Comnenus took advantage of these disorders to enter Constantinople, where he was received with almost divine honours, and overthrew the regents. His arrival was celebrated by a barbarous massacre of the Latins in Constantinople, which he made no attempt to stop. He allowed Alexius to be crowned, but forced him to consent to the death of all his friends, including his mother, his sister and the Caesar, and refused to allow him the smallest voice in public affairs. The betrothal in 1180 of Alexius with Agnes, daughter of Louis VII. of France, a child of nine, was quashed, and he was married to Irene, daughter of Andronicus. The latter was now formally proclaimed as co-emperor, and not long afterwards, on the pretext that divided rule was injurious to the Empire, he caused Alexius to be strangled with a bow-string.

(J. B. B.)

ALEXIUS III. (Angelus), emperor of the East, was the second son of Andronicus Angelus, nephew of Alexius I. In 1195, while his brother Isaac II. was away hunting in Thrace, he was proclaimed emperor by the troops; he captured Isaac at Stagira, in Macedonia, put out his eyes, and kept him henceforth a close prisoner, though he had been redeemed by him from captivity at Antioch and loaded with honours. To compensate for this crime and to confirm his position as emperor, he had to scatter money so lavishly as to empty his treasury, and to allow such licence to the officers of the army as to leave the empire practically defenceless. He consummated the financial ruin of the state. The empress Euphrosyne tried in vain to sustain his credit and his court; Vatatzes, the favourite instrument of her attempts at reform, was assassinated by the emperor's orders. Eastward the empire was overrun by the Turks; from the north Bulgarians and Vlachs descended unchecked to ravage the plains of Macedonia and Thrace; while Alexius squandered the public treasure on his palaces and gardens. Soon he was threatened by a new and yet more formidable danger. In 1202 the western princes assembled at Venice, bent on a new crusade. To them Alexius, son of the deposed Isaac, made appeal, promising as a crowning bribe to heal the schism of East and West if they would help him to depose his uncle. The crusaders, whose objective had been Egypt, were persuaded to set their course for Constantinople, before which they appeared in June 1203, proclaiming the emperor Alexius IV. and summoning the capital to depose his uncle. Alexius III., sunk in debauchery, took no efficient measures to resist. His son-in-law, Lascaris, who was the only one to do anything, was defeated at Scutari, and the siege of Constantinople began. On July 17 the crusaders, the aged doge Dandolo at their head, scaled the walls and took the city by storm. During the fighting and carnage that followed Alexius hid in the palace and finally, with one of his daughters, Irene, and such treasures as he could collect, got into a boat and escaped to Develtin in Thrace leaving his wife, his other daughters and his empire to the victors. Isaac, drawn from his prison and robed once more in the imperial purple, received his son in state.

Shortly afterwards Alexius made an effort in conjunction with Murzuphlus (Alexius V.) to recover the throne. The attempt was unsuccessful and, after wandering about Greece, he surrendered with Euphrosyne, who had meanwhile joined him, to Boniface of

Montferrat, then master of a great part of the Balkan peninsula. Leaving his protection he sought shelter with Michael, despot of Epirus, and then repaired to Asia Minor, where his son-in-law, Lascaris, was holding his own against the Latins. Alexius, joined by the sultan of Iconium (Konia) now demanded the crown of Lascaris, and on his refusal marched against him. Lascaris, however, defeated and took him prisoner. Alexius was relegated to a monastery at Nicaea, where he died on some date unknown.

See the records of Nicetas Acominatus, George Acropolites, Nicephorus Gregoras; and the sources quoted for the Fourth Crusade in the article CRUSADES.

(J. B. B.)

ALEXIUS IV. (d. 1204), Byzantine Emperor, 1203–04. When Isaac II. was dethroned and blinded by his brother Alexius III., his son Alexius escaped, in 1201, to Germany, where he persuaded his brother-in-law, Philip of Suabia, and Boniface of Montferrat, the leader of the crusaders, to divert the fourth crusade to Constantinople. By 1203 Isaac was restored, with Alexius as joint emperor, but they were unable to fulfil the promises made to the crusaders that they would contribute men and money to the expedition to Jerusalem and would force the East to conform to the Western Church. In Jan. 1204 quarrels broke out between the crusaders and the Greeks, who revolted under the leadership of Murzuphlus. An officer, Canabus, was put on the throne, but was imprisoned by Murzuphlus, who had Alexius strangled, while Isaac died of shock. At this the crusaders, in self-defence against the Greeks, stormed and captured Constantinople a second time and elected Baldwin of Flanders as Latin Emperor. (See CRUSADES; also DANDOLO.)

ALEXIUS V., eastern Roman emperor, was proclaimed emperor Feb. 5, 1204, during the siege of Constantinople by the Latins (fourth crusade). His name was Alexius Ducas Murzuphlus, and he was a connection of the imperial house of the Angeli. His elevation was the result of a revolution in the city against Isaac II. and Alexius IV. He conducted the defence with great bravery till it became hopeless (April 12), whereupon he fled. He would then have made common cause with Alexius III. against the Latins, but was blinded by that ex-monarch and fell into the hands of the crusaders, who put him to death by casting him from the top of the Pillar of Theodosius as the murderer of Alexius IV.

ALEXIUS MIKHAILOVICH (1629–1676), tsar of Muscovy, the son of Tsar Michael Romanov and Eudoxia Stryeshnevaya, was born on March 9, 1629. A youth at his father's death (1645), he was committed to the care of Boris Ivanovich Morozov, who recognized the needs of his country and was accessible to Western ideas. He secured the truce with Poland and avoided complications with the Porte. His domestic policy was equitable, and aimed at relieving the public burdens by limiting the privileges of foreign traders and abolishing many useless and expensive court offices. On Jan. 17, 1648, he procured the marriage of the tsar with Maria Miloslavskaya, and he himself married her sister Anna ten days later.

The Miloslavskis were typical self-seeking 17th century boyars, whose extortions made them generally detested. In May 1648 the people of Moscow rose against them, and the young tsar was compelled to dismiss both them and their patron Morozov. There were disquieting disturbances all over the tsardom culminating in dangerous rebellions at Pskov and Great Novgorod, with which the Government was so unable to cope that it surrendered, practically granting the malcontents their own terms. The metropolitan Nikon (q.v.), who had displayed tact and courage at Great Novgorod, in consequence became in 1651 the tsar's chief minister.

In 1653 the weakness and disorder of Poland, which had just emerged from the savage Cossack war, encouraged Alexius to attempt to recover from her secular rival the old Russian lands. The campaign of 1654 was an uninterrupted triumph, and scores of towns, including the important fortress of Smolensk, fell into the hands of the Muscovites. In Jan. 1655 the rout of Ochmatov arrested their progress; but in the summer of the same year, the sudden invasion by Charles X. of Sweden for the moment swept the Polish State out of existence; the Muscovites, unop-

posed, quickly appropriated nearly everything which was not already occupied by the Swedes, and when at last the Poles offered to negotiate, the whole grand-duchy of Lithuania was the least of the demands of Alexius.

Fortunately for Poland, the tsar and the king of Sweden now quarrelled over the spoil, and at the end of May 1656 Alexius declared war against him. Great things were expected of the Swedish war, but nothing came of it. Dorpat was taken, but countless multitudes were lost in vain before Riga. In the meantime Poland had so far recovered herself as to become much more dangerous than Sweden. The tsar rid himself of the Swedes by the peace of Kardis (July 2, 1661), whereby Muscovy retroceded all her conquests. The Polish war dragged on for six years longer and was then concluded by a truce, nominally for 13 years, which proved the most durable of treaties.

By the truce of Andrussowo (Feb. 11, 1667) Vitebsk, Polotsk and Polish Livonia were restored to Poland, but Smolensk and Kiev remained in the hands of the Muscovites, together with the whole eastern bank of the Dnieper. This truce was the achievement of Athanasy Orduin-Nashchokin, the first Russian chancellor and diplomatist in the modern sense, who after the disgrace of Nikon became the tsar's first minister till 1670, when he was superseded by Artamon Matveyev. Nikon had become too powerful for the tsar, and on the return of Alexius from the Polish war there arose a conflict over the question of ecclesiastical authority in the State, ending in Nikon's trial and deprivation in 1667.

Alexius had the art of discovering good advisers and the good sense to employ them. He was not a man of strong character, or he would not have submitted to the dictation of Nikon. He was naturally progressive, though in a timid way, or he would not have supported the reforms of Matveyev. He was learned in his own way, wrote verses and began a history of his own time. His last years were tranquil, in spite of the rebellion of Stenka Razin. By his first wife he had a large family, and by his second, Natalia Narushkina, two children, the tsarevich Peter and the tsarevna Natalia.

See Robert Nisbet Bain, *The First Romanovs* (London, 1905).

ALEXIUS PETROVICH (1690-1718), Russian tsarevich, the sole surviving son of Peter I. and Eudoxia Lopukhina, was born on Feb. 19, 1690. The young tsar married the *boyarinnya* Lopukhina at his mother's command. From the first, her society bored Peter unspeakably, and, after the birth (Oct. 3, 1691) of their second short-lived son Alexander, he practically deserted her. The young Alexius was ignored by his father till he was nine years old, and was privately educated. In 1703 he was ordered to the field as a private in a bombardier regiment in the army. In 1704 he was present at the capture of Narva.

In 1708 Peter sent Alexius to Smolensk to collect provender and recruits, and thence to Moscow to fortify it against Charles XII. At the end of 1709 he went to Dresden for 12 months for finishing lessons in French and German, mathematics and fortification, and, his education completed, he was married on Oct. 14, 1711, greatly against his will, to the Princess Charlotte of Brunswick-Wolfenbüttel. Three weeks later the bridegroom was hurried away by his father to Thorn to superintend the provisioning of the Russian troops in Poland. For the next 12 months Alexius was kept constantly on the move. His wife joined him at Thorn in December, but in April 1712 a peremptory ukase ordered him off to the Army in Pomerania, and in the autumn of the same year he was forced to accompany his father on a tour of inspection through Finland. Immediately on his return from Finland, Alexius was despatched by his father to Staraya Rusya and Ladoga to see to the building of new ships. This was the last commission entrusted to him. On his return to the capital, Peter, in order to see what progress his son had made in mechanics and mathematics, asked him to draw something of a technical nature for his inspection. Alexius, in order to escape such an ordeal, disabled his right hand by a pistol-shot. In no other way could the tsarevich have offended his father so deeply. He had behaved like a cowardly recruit who mutilates himself to escape military service. After this, Peter employed him no more. He

no longer pressed him to attend public functions. Alexius rejoiced at this welcome change, but he had cause rather to fear it.

On Oct. 22, 1715, Alexius's consort, the Princess Charlotte, died, after giving birth to a son, the Grand-duke Peter, afterwards Peter II. On the day of the funeral, Peter addressed to Alexius a stern letter urging him no longer to resemble the slothful servant in the parable, and threatening to cut him off if he did not acquiesce in his father's plans. Alexius wrote a pitiful reply to his father, offering to renounce the succession in favour of his baby half-brother Peter, who had been born the day after the Princess Charlotte's funeral. In Jan. 1716 he wrote to his father for permission to become a monk. Still Peter did not despair. On Aug. 26, 1716, he wrote to Alexius from abroad urging him, if he desired to remain tsarevich, to join him and the Army without delay.

But Alexius fled to Vienna and placed himself under the protection of his brother-in-law, the Emperor Charles VI., who sent him for safety first to the Tyrolean fortress of Ahrenberg, and finally to the castle of San Elmo at Naples. He was accompanied throughout his journey by his mistress, the Finnish girl Afrosina. That the emperor sincerely sympathized with Alexius, and suspected Peter of harbouring murderous designs against his son, is plain from his confidential letter to George I. of England, whom he consulted.

Peter's agitation was extreme. The flight of the tsarevich was a reproach and a scandal. He must be recovered and brought back to Russia at all hazards. This task was accomplished by Count Peter Tolstoi, the most subtle and unscrupulous of Peter's servants; but terrorized though he was, Alexius would only consent to return on his father's solemnly swearing, "before God and His judgment seat," that if he came back he should not be punished, but cherished as a son and allowed to live quietly on his estates and marry Afrosina.

On Jan. 31, 1718, the tsarevich reached Moscow. On Feb. 18 a "confession" was extorted from Alexius which implicated most of his friends, and he then publicly renounced the succession to the throne in favour of the baby grand-duke Peter Petrovich. A reign of terror ensued, in the course of which the ex-tsaritsa Eudoxia was dragged from her monastery and publicly tried for alleged adultery, while all who had in any way befriended Alexius were impaled, broken on the wheel or otherwise done to death. In April 1718 fresh confessions were extorted from Alexius, now half idiotic with fright. Yet even now there were no actual facts to go upon. The worst that could be brought against him was that he had "wished" his father's death. In the eyes of Peter, his son was now a self-convicted and most dangerous traitor, whose life was forfeit. But there was no getting over the fact that his father had sworn "before the Almighty and His judgment seat" to pardon him and let him live in peace if he returned to Russia. But did the enormity of the tsarevich's crime absolve the tsar from the oath? This question was solemnly submitted by Peter to a grand council of prelates, senators, ministers and other dignitaries on June 13, 1718. The clergy left the matter to the tsar's own decision. The temporal dignitaries declared the evidence to be insufficient and suggested that Alexius should be examined by torture. Accordingly, on June 19, the weak and ailing tsarevich received 25 strokes with the knout (as then administered, nobody ever survived 30), and on the 24th 15 more. He expired two days later in the guard-house of the citadel of St. Petersburg, two days after the senate had condemned him to death for "imagining" rebellion against his father, and for "hoping" for the co-operation of the common people and the armed intervention of his brother-in-law, the emperor.

See R. N. Bain, *The First Romanovs* (London, 1905); Comte de Vogue, *Mazeppa. Un changement de règne* (Paris, 1884).

ALFA or HALFA, the North African name of a species of esparto grass. (See ESPARTO.)

ALFALFA, the name in the United States, Canada and certain other countries for the leguminous plant *Medicago sativa*, known elsewhere as lucerne (see LUCERNE).

ALFALFA WEEVIL, a snout-beetle, or weevil (*Phytonomus posticus*) of Old World origin, which feeds upon alfalfa, or

lucerne (*Medicago sativa*). Although widely distributed in Europe, where its host plant is extensively grown, it attracted little attention until it was accidentally introduced into the United States in the early years of the present century. It appeared suddenly in the vicinity of Salt Lake City, a region where the alfalfa crop is of great importance, multiplied and spread rapidly, causing great alarm to the agricultural and live-stock industries. It spread steadily at the rate of from 10 to 20 m. a year, and in 1927 occurred in great numbers through the Great Basin and the Snake river watershed, in large areas of the Colorado and North Platte drainage basins, and in the territory of the Yellowstone and Sacramento rivers. It is a constant threat to the great alfalfa regions to the east, and its spread cannot be prevented by regulating the production and marketing of the crop, since it feeds on other leguminous plants, some of which are wild.

The adult weevil is dark brown in colour and about $\frac{3}{8}$ in. long. In this stage it passes the winter, usually in crevices in the ground. In the spring the adults begin feeding on the earliest growth of the plant, and lay their eggs either in old, dry stems or in the living stems. In warm weather these eggs hatch in from one to two weeks, and the young larvae begin to feed on the leaves, especially on the opening tips, rapidly skeletonizing them—so rapidly, in fact, that the plant is unable to outgrow the injury. When full grown, the greenish larvae spin loose cocoons from which adults emerge in the summer. The cocoons are found attached to the stems, in curled leaves or on the ground.

During the first nine years in America, the weevil not only spread rapidly but nearly destroyed the first crop of alfalfa each year. Since then there have been fluctuations in the amount of damage, due probably to climatic changes. Systematic studies have been carried on by the Federal bureau of entomology ever since the insect was first discovered, and important investigations have been made by the official entomologists of Utah and the neighbouring States. Ten species of parasites have been imported from Europe by the Federal experts, and one of these (*Bathyplectes curculionis*) is thoroughly established and has spread throughout most of the infested territory. In some localities it has been known to kill 90% of the weevil larvae; but the rate of increase of the weevil is so rapid that even this percentage does not bring about control, and artificial remedial measures must be relied upon.

Of the artificial measures, spraying or dusting the first crop at just the proper time (varying according to conditions) with powdered arsenate of calcium has been found to be the most effective, by which method it is still possible to grow alfalfa with more or less profit, in spite of the weevil. A full account of methods and machinery will be found in *Farmers' Bulletin*, No. 1,528, U.S. Department of Agriculture. (L. O. H.)

ALFANO, FRANCO (1877–), Italian composer, was born at Posilipo, near Naples, March 8, 1877. He studied at Naples and Leipzig and by his numerous works for the stage has acquired a leading position among his contemporaries. He has also written orchestral and chamber works of merit. For a time he was director of the Liceo Musicale Rossini at Bologna and later went to Turin in a similar capacity. To him was entrusted the task of completing Puccini's unfinished opera *Turandot*.

ALFELD, chief town of a subdivision of the district of Hildesheim, in the Prussian province of Hanover, on the river Leine, about 15 m. S.S.W. of Hildesheim. Pop. (1925) 7,020. It has a handsome church with twin spires. Its industries embrace paper-making, iron-founding and the production of agricultural machinery.

ALFIERI, VITTORIO, COUNT (1749–1803), famous tragic dramatist of Italy, was born at Asti in Piedmont, of rich and noble parents. His father died when he was an infant and his mother married again, but an uncle took an interest in his education and sent him in his tenth year to the Academy of Turin. By the death of this uncle he was left, at the age of 14, to enjoy without control his vast paternal inheritance, augmented by the recent accession of his uncle's fortune; but for three more years he remained at the academy, though he seems to have learned very little there except contempt for his studies and for the life

which he saw about him. Eager to escape from it, he obtained leave of the king to travel, and left Turin in 1766 under the care of an English tutor, from whom, however, he soon parted.

For nearly seven years he travelled about Europe, visiting most of the capitals, and indulging in a series of amorous adventures, of which he gives some account in his interesting autobiography; but although much of his time was wasted in dissipation, he found in England the political liberty which became his ideal, and in France the literature which seems to have influenced him most profoundly. He studied Voltaire, Rousseau and, above all, Montesquieu; and his reading confirmed in him that love of freedom and hatred of all tyranny which were henceforward his most marked characteristics.

In 1772 he returned to Turin, but two more years were wasted in yet another intrigue before he found in Plutarch's *Lives*—his "book of books," as he called it—a stimulus to literary composition, and, identifying himself with the love-sick Antony, wrote a play entitled *Cleopatra*, which was acted in 1775. Well aware of its defects, he persuaded the producer to withdraw it after the second performance; but its immediate success filled him with ambition to excel as a dramatist, and, since no great tragic poet had yet arisen in Italy, he determined to devote himself to the composition of tragedies.

As a Piedmontese who had spent so many years abroad, he was gravely handicapped by his ignorance of classical Italian, and indeed his first two tragedies, *Filippo* and *Polinice*, were conceived and written in French prose. Much hard study was required before he could translate them into Italian blank verse (for which Cesarotti's version of *Ossian* served him as a model), but he had at last found an object in life, and so ardently did he devote himself to its achievement that in eight years he had 14 tragedies to his credit, ten of which were published at Siena in 1783. During the same period he found time to write many translations and original lyrics, including five odes on American independence, as well as a treatise, *Della Tirannide*, which however was not published until many years later. His first series of tragedies culminated in *Saul*, which many critics besides himself have regarded as his best play, and when he wrote it he intended it to be his last.

Meanwhile, in 1777, he had found in the Countess of Albany (*q.v.*) a new love, to whom he remained faithful for the rest of his life; and, in order to be free to follow her, in 1778 he ended his allegiance to Piedmont by making over his estate there to his sister. One of his plays, *Maria Stuarda*, was dedicated to the countess, but it was not until she had left Italy to reside at Colmar in Alsace (1784) that he was able to see her freely, and thenceforward until his death he lived with her. Immediately after Vittorio Alfieri joined her he was moved to break his previous resolution and write five more tragedies, one of which, *Mirra*, has been preferred by some good judges even to *Saul*; and it was at this time, too, that he completed his treatise *Del Principe e delle Lettere*, an exercise in the manner of Machiavelli, which was not published until 1801. From Alsace the lovers moved to Paris, and there in 1788–89 Alfieri supervised the printing of a complete edition of his tragedies by Didot.

When the Revolution began he hailed it with an ode on the taking of the Bastille; but the excesses of the populace could not fail to disgust a republican who, as Byron said of him, "was an aristocrat at heart." In 1792 he escaped with the Countess from France and settled in Florence, where they lived for the rest of his life. The property which he had left in France was confiscated, on the plea that he was an emigrant, and this fact helps to explain the hatred of all things French which found expression in his *Misogallo*, a collection of violent polemics in prose and verse, which was published in 1799, the year when the French troops first entered Florence. Although he never ceased to rage against tyranny—not only of kings and priests, but of revolutionaries as well—the last years of his life were undisturbed and he devoted them to quiet study, teaching himself Greek, and even trying to write comedies, for which he had no real gift. These, like his autobiography, his satires, and many of his lyric poems, were not published until after his death, which occurred at

Florence, Oct. 8, 1803. He was buried in Santa Croce, and there the Countess of Albany caused a monument by Canova to be dedicated to his memory seven years later. A collected edition of his works was published at Florence in 22 volumes (1805-15).

Alfieri's literary reputation rests chiefly on his 19 tragedies, which were all strictly classical in form, adhering even more closely than their models to the unity of action or interest. Subordinate episodes and verbal ornaments were ruthlessly excluded from them, and no more than four principal characters were admitted on the stage. But the genius of their author was essentially lyrical, and the situation which he treats most often and with most success—that of the hero defying tyranny—is one in which he was able to identify himself with the "splendid rebel," and use him as a mouthpiece for his passionate denunciation of tyrants or praises of freedom. For this his somewhat harsh style, *pensato e non cantato*, which was an offence to his contemporaries, is now recognized to be the most appropriate vehicle.

But plays written to serve as weapons for political warfare are rarely successful dramatically, and Alfieri too often sacrificed dramatic propriety to special pleading. It is as a precursor of the Risorgimento that he is specially honoured in Italy to-day, and it was in a section of the *Misogallo* that he first turned from generalizations about freedom to make a direct appeal to his countrymen to recover their own. By that appeal and by many of his lyrics, which he claimed to have written as spurs to arouse the new generations and make them worthy of their Roman ancestors, he certainly helped to revive the national spirit and earned the title of *Vate d'Italia* by which he is honoured to-day.

Walker, *Historical Memoir on Italian Tragedy* (1799); *Giorn. de Pisa*, tom. lviii.; Centofanti, *Life of Alfieri* (1842); Emilio Teza, *Vita, Giornali, Lettere di Alfieri* (1861); Antonini and Cognetti, *Vittorio Alfieri* (1898).

ALFORD, HENRY (1810-1871), English divine and scholar, was born in London on Oct. 7, 1810, of a Somersetshire family which had given five consecutive generations of clergymen to the Church of England. He was a precocious lad who wrote Latin odes and a history of the Jews before he was ten. He graduated from Trinity college, Cambridge, in 1832, being 34th wrangler and 8th classic, and in 1834 became a fellow of his college. Alford was vicar of Wymeswold (1835-53), preached at Quebec chapel in London (1853-57) and was dean of Canterbury from 1857 to his death on Jan. 12, 1871.

Dean Alford was a man of many and varied accomplishments. He published some volumes of verse, wrote some popular hymns, and was the first editor of the *Contemporary Review*. But his chief fame rests upon his monumental edition of the New Testament in Greek, which occupied him from 1841 to 1861. In this work he first brought before English students a careful collation of the readings of the chief mss., and the researches of the ripest continental scholarship of his day. Though more recent research, patristic and papyral, has largely changed the method of New Testament exegesis, Alford's work is still a quarry where the student can dig with a good deal of profit.

His *Life*, written by his widow, appeared in 1873 (Rivington).

ALFRED or **AELFRED**, known as **THE GREAT** (848?-900), king of England, was born at Wantage, and was the fourth son of King Aethelwulf and his first wife Osburh. He seems to have been a child of singular attractiveness and promise, and stories of his boyhood were remembered. At the age of five (853) he was sent to Rome, where he was confirmed by Leo IV., who is also stated to have "hallowed him as king." Later writers interpreted this as an anticipatory crowning in preparation for his ultimate succession to the throne of Wessex. That, however, could not have been foreseen in 853, as Alfred had three elder brothers living. It is probably to be understood as investiture with the consular insignia, or possibly with some titular royalty such as that of the under-kingdom of Kent. In 855 Alfred again went to Rome with his father Aethelwulf, returning towards the end of 856. About two years later his father died.

During the short reigns of his two eldest brothers, Aethelbald and Aethelbert, nothing is heard of Alfred. But with the acces-

sion of the third brother Aethelred (866), the public life of Alfred begins, and he enters on his great work of delivering England from the Danes. It is in this reign that Asser applies to Alfred the unique title of *secundarius*, which seems to indicate a position analogous to that of the Celtic *tanist*, a recognized successor, closely associated with the reigning prince. It is probable that this arrangement was definitely sanctioned by the witenagemot, to guard against the danger of a disputed succession should Aethelred fall in battle. In 868 Alfred married Ealhswith, daughter of Aethelred Mucill, an ealdorman of the Gaini, an unidentified district. The same year the two brothers made an unsuccessful attempt to relieve Mercia from the pressure of the Danes. For nearly two years Wessex had a respite. But at the end of 870 the storm burst; and the year which followed has been rightly called "Alfred's year of battles." Nine general engagements were fought with varying fortunes, though the place and date of two of them have not been recorded. A successful skirmish at Englefield, Berkshire (Dec. 31, 870), was followed by a severe defeat at Reading (Jan. 4, 871), and this, four days later, by the brilliant victory of Ashdown, near Compton Beauchamp in Shrivensham Hundred. On Jan. 22, the English were again defeated at Basing, and on March 22, at Marton, Wiltshire, the two unidentified battles having perhaps occurred in the interval.

In April Aethelred died, and Alfred succeeded to the whole burden of the contest. While he was busied with his brother's funeral, the Danes defeated the English in his absence at an unnamed spot, and once more in his presence at Wilton in May. After this peace was made, and for the next five years the Danes were occupied in other parts of England, Alfred merely keeping a force of observation on the frontier. But in 876 part of the Danes managed to slip past him and occupied Wareham; whence, early in 877, under cover of treacherous negotiations, they made a dash westwards and seized Exeter. Here Alfred blockaded them, and a relieving fleet having been scattered by a storm, the Danes had to submit and withdrew to Mercia. But in Jan. 878 they made a sudden swoop on Chippenham, where Alfred had been keeping his Christmas, "and most of the people they reduced except the King Alfred, and he with a little band made his way . . . by wood and swamp, and after Easter he . . . made a fort at Athelney, and from that fort kept fighting against the foe" (*Chron.*). The idea that Alfred during his retreat at Athelney was a helpless fugitive rests upon the foolish legend of the cakes. In reality he was organizing victory.

By the middle of May his preparations were complete and he moved out of Athelney, being joined on the way by the levies of Somersetshire, Wiltshire and Hampshire. The Danes on their side moved out of Chippenham, and the two armies met at Edington in Wiltshire. The result was a decisive victory for Alfred. The Danes submitted. Guthrum, the Danish king, and 29 of his chief men accepted baptism. By the next year (879) not only Wessex, but Mercia west of Watling Street, was cleared of the invader. This is the arrangement known as the peace of Wedmore (878), though no document embodying its provisions is in existence. And though for the present the north-eastern half of England, including London, remained in the hands of the Danes, in reality the tide had turned, and western Europe was saved from the danger of becoming a heathen Scandinavian power.

For the next few years there was peace, the Danes being kept busy on the continent. A landing in Kent in 884 or 885¹, though successfully repelled, encouraged the East Anglian Danes to revolt. The measures taken by Alfred to repress this revolt culminated in the capture of London in 885 or 886, and the treaty known as Alfred and Guthrum's peace, whereby the boundaries of the treaty of Wedmore (with which this is often confused) were materially modified in Alfred's favour. Once more for a time there was a lull; but in the autumn of 892 (893) the final storm burst. The Danes amounting in the aggregate to 330 sail, crossed to England in two divisions, finding their position on the Conti-

¹Where alternative dates are given the later date is that of the *Saxon Chronicle*. But the evidence of the Continental Chronicles makes it probable that the *Saxon Chronicle* is a year in advance of the true chronology in this part.

nent becoming more and more precarious, and entrenched themselves, the larger body at Appledore and the lesser under Haesten at Milton in Kent. The fact that the new invaders brought their wives and children with them shows that this was no mere raid, but a deliberate attempt, in concert with the Northumbrian and East Anglian Danes, to conquer England. Alfred, 893 (894), took up a position whence he could observe both forces.

While he was negotiating with Haesten the Danes at Appledore broke out and struck north-westwards, but were overtaken by Alfred's eldest son, Edward, and defeated in a general engagement at Farnham, and driven to take refuge in Thorney Island in the Hertfordshire Colne, where they were blockaded and ultimately compelled to submit. They then fell back on Essex, and after suffering another defeat at Benfleet coalesced with Haesten's force at Shoebury. Alfred had been on his way to relieve his son at Thorney when he heard that the Northumbrian and East Anglian Danes were besieging Exeter and an unnamed fort on the coast of North Devon. Alfred at once hurried westwards and raised the siege of Exeter; the fate of the other place is not recorded.

Meanwhile the force under Haesten set out to march up the Thames valley, possibly with the idea of assisting their friends in the west. But they were met by a large force under the three great ealdormen of Mercia, Wiltshire and Somersetshire, and forced to head off to the north-west, being finally overtaken and blockaded at Buttington, which some identify with Buttington Tump at the mouth of the Wye, others with Buttington near Welshpool. An attempt to break through the English lines was defeated with loss; those who escaped retreated to Shoebury. Then after collecting reinforcements they made a sudden dash across England and occupied the ruined Roman walls of Chester. The English did not attempt a winter blockade, but contented themselves with destroying all the supplies in the neighbourhood. And early in 894 (895) want of food obliged the Danes to retire once more to Essex.

At the end of this year and early in 895 (896) the Danes drew their ships up the Thames and Lea and fortified themselves 20 miles above London. A direct attack on the Danish lines failed, but later in the year Alfred saw a means of obstructing the river so as to prevent the egress of the Danish ships. The Danes realized that they were out-manoeuvred. They struck off north-westwards and wintered at Bridgnorth. The next year, 896 (897) they abandoned the struggle. Some retired to Northumbria, some to East Anglia; those who had no connexions in England withdrew to the continent. The long campaign was over.

The result testifies to the confidence inspired by Alfred's character and generalship, and to the efficacy of the military reforms initiated by him. These were (1) the division of the *fyrd* or national militia into two parts, relieving each other at fixed intervals, so as to ensure continuity in military operations; (2) the establishment of fortified posts (burgs) and garrisons at certain points; (3) the enforcement of the obligations of thanehood on all owners of five hides of land thus giving the King a nucleus of highly equipped troops. After the final dispersal of the Danish invaders Alfred turned his attention to the increase of the Navy, and ships were built according to the King's own designs, partly to repress the ravages of the Northumbrian and East Anglian Danes on the coasts of Wessex, partly to prevent the landing of fresh hordes. This is not, as often asserted, the beginning of the English Navy. There had been earlier naval operations under Alfred. One naval engagement was certainly fought under Aethelwulf (851), and earlier ones, possibly in 833 and 840. Nor were new ships a great success, as we hear of them grounding in action and foundering in a storm.

Much, too, was needed in the way of civil re-organization, especially in the districts ravaged by the Danes. In the parts of Mercia acquired by Alfred, the shire system seems now to have been introduced for the first time. This is the one grain of truth in the legend that Alfred was the inventor of shires, hundreds and tithings. The finances also would need careful attention; but the subject is obscure, and we cannot accept Asser's description of Alfred's appropriation of his revenue as more than an ideal

sketch. Alfred's care for the administration of justice is testified both by history and legend; and the title "protector of the poor" was his by unquestioned right.

Of the action of the witenagemot we do not hear very much under Alfred. That he was anxious to respect its rights is conclusively proved, but both the circumstances of the time and the character of the king would tend to throw more power into his hands. The legislation of Alfred probably belongs to the later part of the reign, after the pressure of the Danes had relaxed. The details of it cannot be discussed here.

Asser speaks grandiosely of Alfred's relations with foreign powers, but little definite information is available. He certainly corresponded with Elias III., the patriarch of Jerusalem, and probably sent a mission to India. Embassies to Rome conveying the English alms to the pope were fairly frequent; while Alfred's interest in foreign countries is shown by the insertions which he made in his translation of *Orosius*. His relations to the Celtic princes in the southern half of the island are clearer. Comparatively early in his reign the South Welsh princes, owing to the pressure on them of North Wales and Mercia, commended themselves to Alfred. Later in the reign the North Welsh followed their example, and the latter co-operated with the English in the campaign of 893 (894). The Celtic principality in Cornwall which seems to have survived at least till 926, must long have been practically dependent on Wessex. That Alfred sent alms to Irish as well as to continental monasteries may be accepted on Asser's authority; the visit of the three pilgrim "Scots" (*i.e.*, Irish) to Alfred in 891 is undoubtedly authentic; the story that he himself in his childhood was sent to Ireland to be healed by St. Modwenna, though mythical, may point to Alfred's interest in that island.

The history of the church under Alfred is most obscure. The Danish inroads had told heavily upon it; the monasteries had been special points of attack, and though Alfred founded two or three monasteries and imported foreign monks, there was no general revival of monasticism under him. To the ruin of learning and education wrought by the Danes, and the practical extinction of the knowledge of Latin even among the clergy, the preface to Alfred's translation of Gregory's *Pastoral Care* bears eloquent testimony. It was to remedy these evils that he established a court school, after the example of Charles the Great; for this he imported scholars like Grimbald and John the Saxon from the continent and Asser from South Wales; for this, above all, he put himself to school, and made the series of translations for the instruction of his clergy and people, most of which still survive. These belong unquestionably to the later part of his reign, not improbably to the last four years of it, during which the chronicles are almost silent.

Apart from the lost *Handboc* or *Encheiridion*, which seems to have been merely a commonplace-book kept by the King, the earliest work to be translated was the *Dialogues of Gregory*, a book enormously popular in the Middle Ages. In this case the translation was made by Alfred's great friend Werferth, bishop of Worcester, the king merely furnishing a preface.

The next work to be undertaken was Gregory's *Pastoral Care*, especially for the benefit of the clergy. In this Alfred keeps very close to his original; but the introduction which he prefixed to it is one of the most interesting documents of the reign, or indeed of English history.

The next two works taken in hand were historical, the *Universal History of Orosius* and Bede's *Ecclesiastical History of the English People*. The priority should probably be assigned to the *Orosius*, but the point has been much debated. In the *Orosius*, by omissions and additions, Alfred so remodels his original as to produce an almost new work; in the *Bede* the author's text is closely adhered to, no additions being made, though most of the documents and some other less interesting matters are omitted. Of late years doubts have been raised as to Alfred's authorship of the *Bede* translation. But the sceptics cannot be regarded as having proved their point.

We come now to what is in many ways the most interesting of Alfred's works, his translation of Boethius's *Consolation of Phi-*

losophy, the most popular philosophical manual of the middle ages. Here again Alfred deals very freely with his original and though the late Dr. G. Schepss showed that many of the additions to the text are to be traced not to Alfred himself, but to the glosses and commentaries which he used, still there is much in the work which is solely Alfred's and highly characteristic of his genius. It is in the *Boethius* that the oft-quoted sentence occurs: "My will was to live worthily as long as I lived, and after my life to leave to them that should come after, my memory in good works." The book had come down to us in two mss. only. In one of these the poems with which the original is interspersed are rendered into prose, in the other into alliterating verse. The authorship of the latter has been much disputed; but probably they also are by Alfred. Of the authenticity of the work as a whole there has never been any doubt.

The last of Alfred's works is one to which he gave the title *Blostman*; i.e., "Blooms" or Anthology. The first half is based mainly on the *Soliloquies* of St. Augustine, the remainder is drawn from various sources, and contains much that is Alfred's own and highly characteristic of him. The last words of it may be quoted; they form a fitting epitaph for the noblest of English kings. "Therefore he seems to me a very foolish man, and very wretched, who will not increase his understanding while he is in the world, and ever wish and long to reach that endless life where all shall be made clear." Besides these works of Alfred's, the *Saxon Chronicle* almost certainly, and a *Saxon Martyrology*, of which fragments only exist, probably owe their inspiration to him. A prose version of the first 50 Psalms has been attributed to him; and the attribution, though not proved, is perfectly possible. How Alfred passed to "the life where all things are made clear" we do not know. The very year is uncertain. The arguments on the whole are in favour of 900. The day was Oct. 26. Alike for what he did and for what he was, there is none to equal Alfred in the whole line of English sovereigns, and no monarch in history ever deserved more truly the epithet of Great.

BIBLIOGRAPHY.—The chief original authorities for the reign of Alfred are the so-called *Life* by Asser (best edition by W. H. Stevenson, Clarendon Press, 1904); and the *Saxon Chronicles* (text and notes by Earle and Plummer, Clar. Press, 1892-99); parallel texts and translation, Thorpe (1861), Rolls Series; translation alone, Joseph Stevenson in *Church Historians of England*, vol. ii. (1853). The above sketch is based mainly on C. Plummer's *Life and Times of Alfred the Great* (Clar. Press, 1902). Of earlier biographies that by Pauli is still of great value: *König Alfred* (Berlin, 1851); Eng. trans. by Thorpe (Bohn, 1853). Of recent works mention may be made of *Alfred the Great, Chapters on his Life and Times*, by various authors edited by Alfred Bowker (1899); Earle, *The Alfred Jewel* (Clar. Press, 1901). See also B. A. Lees, *Alfred the Great* (New York, 1915); F. M. Stenton, "Aethelwold's account of the last years of King Alfred," in the *English Historical Review* (1909).

For the bibliography of Alfred's works in general see Wülker, *Grundriss zur Gesch. der angelsächsischen Literatur*, 386-451 (Leipzig, 1885). Only the more recent and accessible editions are mentioned here. *Laws: The Legal Code of Aelfred the Great* (M. H. Turk, Halle, 1893). For the Anglo-Saxon laws as a whole see Liebermann, *Gesetze der Angelsachsen* (Halle, 1903, 1906). Earlier editions, Schmid (1858); Thorpe (1840). *Gregory's Dialogues*: Hans Hecht, in Grein's *Bibliothek der angels. Prosa* (1900). *Gregory's Pastoral Care*; H. Sweet, for Early Eng. Text Society (1871-72). (Dissertations by Wack and De Witz, 1889.) *Orosius*: Thorpe (in his translation of Pauli, U.S. 1853); Bosworth (1859); Sweet, E.E.T.S. (1883). (Dissertation: Schelling, *König Aelfred's . . . Orosius*, Halle, 1886.) *Bede*: T. Miller, for E.E.T.S. (1890); Prof. Schipper in Grein's *Bibliothek* (U.S. 1899). *Boethius*: W. J. Sedgfield (Clar. Press, 1899); translation by the same (1900). (Dissertation: G. Schepss, *Archiv für's Studium der neueren Sprachen*, xciv. 14-160.) *Blostman*: First printed by Cockayne in the *Shrine* (1868-69); reprinted, *Englische Studien*, xviii.; new edition by Haugrove, *Yale Studies in English*, xiii. (1902); translation by the same, *ibid.*, xxii. (1904). (Dissertation: F. G. Hubbard, *Modern Language Notes*, ix. 322 seq.) *Anglo-Saxon Chronicle*: see above. *Martyrology*: Cockayne, in the *Shrine*, v.s. *Psalter*: Thorpe (Clar. Press, 1835). ALFRED ERNEST ALBERT (1844-1900), Duke of Saxe-Coburg and Gotha, and Duke of Edinburgh, second son and fourth child of Queen Victoria, was born at Windsor Castle on Aug. 6, 1844. He passed a most creditable examination for midshipman in Aug. 1858, and being appointed to the "Euryalus," at once began

to work hard at the practical part of his profession. In July 1860, while on this ship, he paid an official visit to the Cape. On the abdication of Otto, king of Greece, in 1862, the crown was offered to Prince Alfred, but political conventions of long standing rendered it impossible for the British Government to agree to the proposal. The prince therefore remained in the Navy, and was promoted to the rank of captain Feb. 23, 1866, being then appointed to the command of the "Galatea." On attaining his majority in 1865, the prince was created Duke of Edinburgh and Earl of Ulster, with an annuity of £15,000 granted by Parliament. While still in command of the "Galatea," the duke started from Plymouth on Jan. 24, 1867, for a voyage round the world and visited Australia and India, being received everywhere with enthusiasm. An attempt on his life at Sydney by an Irishman named O'Farrell was the only unfortunate incident. After an absence of 17 months, he returned to England.

The duke married on Jan. 23, 1874, the Grand Duchess Marie Alexandrovna, only daughter of Alexander II., emperor of Russia. He continued his naval duties after his marriage, and held successive high commands until 1893 when he received his baton as admiral of the fleet.

On the death of his uncle, Ernest II., Duke of Saxe-Coburg and Gotha, on Aug. 22, 1893, the vacant duchy fell to the Duke of Edinburgh, for the Prince of Wales had renounced his right to the succession. At first regarded with some coldness as a "foreigner," he gradually gained popularity, and by the time of his death, on July 30, 1900, he had completely won the good opinion of his subjects. The duke was exceedingly fond of music and an excellent violinist, and took a prominent part in establishing the Royal College of Music. He was also a keen collector of glass and ceramic ware, and his collection, valued at 500,000 marks, was presented by his widow to the "Veste Coburg," near Coburg. When he became Duke of Saxe-Coburg he surrendered his English allowance of £15,000 a year, but the £10,000 granted in addition by Parliament on his marriage he retained in order to keep up Clarence House. The duke had one son, who died unmarried on Feb. 6, 1899, and four daughters: Marie (queen of Roumania); Victoria Melita (Grand Duchess Cyril of Russia); Beatrice, who married Don Alphonso of Spain; and Princess Alexandra Louisa Olga Victoria of Hohenlohe-Langenbourg.

ALFRED, OF BEVERLEY, Alredus, Alured or Aluredus, was sacristan of the church of Beverley in the first half of the 12th century. He wrote, apparently about the year 1143, a chronicle entitled *Annales sive Historia de gestis regum Britannie*, in nine books, which begins with the legend of Brutus and carries the history of England down to 1129. This work was edited by T. Hearne (Oxford, 1716). Geoffrey of Monmouth and Simeon of Durham are Alfred's chief sources. Among the Cottonian mss. there is a collection of records relating to Beverley, *Libertates Ecclesiae S. Iohannis de Beverlae*, which is attributed to Alfred, but on no good authority.

ALFRED, a village in Allegany county, N.Y., U.S.A., on the Erie railroad about 75 m. S.E. of Buffalo. It is situated among rugged hills, at the intersection of two valleys. The population was 639 in 1930.

On the west slope of Pine hill, 1,800 ft. above sea-level, is Alfred university (co-educational), which embraces a college (non-sectarian) and a theological seminary (Seventh-Day Baptist). The enrolment in 1926-27 was 564. On grounds adjacent to the college campus, and administered by the university trustees, are the New York State school of clay-working and ceramics (established 1900), a unique institution which confers degrees in ceramic engineering and in applied art, and a New York State school of agriculture (established 1908). Alfred university traces its history to a "select school" organized in 1836, which developed into Alfred academy, chartered 1843. Three buildings were erected on the present campus in 1846, and in 1857 a university charter was secured.

Alfred lies within the territory purchased by Robert Norris in 1791, and is said to have been named after Alfred the Great. The first settlement was made in 1807. Most of the early settlers were Seventh-Day Baptists. The village was chartered in 1887.

ALFRETON, urban district, Derbyshire, England, 14m. N. by E. of Derby, on the L.M.S. railway. Population (1931) 21,232. It lies above a small tributary of the Derwent. The church of St. Martin is Early English and later. The neighbourhood abounds in ironworks, collieries, quarries and potteries, and is thickly populated. To the north-east of Alfreton are South Normanton (population 6,996 in 1921), Blackwell (5,073) and Tibshelf (4,053); to the north Shirland, to the south Ironville, and other busy industrial villages. The foundation of Alfreton is traditionally ascribed to King Alfred.

ALFURS, a general name given to tribes of low culture and mixed origin inhabiting parts of the eastern islands of the Indonesian archipelago, Halmahera, Ceram, Timorlaut and Timor and the adjacent islets. They are probably of Proto-Malay and Indonesian extraction with a strong admixture of Papuan elements; and in Ceram in particular seem to have decided affinities with the dolicho-cephalic people of Oceania. Generally speaking they use bark belts and thigh-cloths, chew betel (tobacco is not used in Ceram), cultivate sago rather than rice, are exogamous, patrilineal and ancestor-worshippers, laying out their dead in trees, but there is a good deal of variation between different groups. Thus the head-hunting (*q.v.*) cult, which is strong in Ceram, takes the form of cannibalism in Timorlaut. In Ceram the women only are tattooed; in Timorlaut both sexes. In Ceram a quasi-secret society is formed for the administration of justice, a tree spirit is invoked for aid in war, and the skull of an enemy or slave is put under the posts of buildings, while head-hunters warn victims of hostile intentions by raiding their gardens and damaging the fruit trees. In Timorlaut warriors swallow a butterfly to obtain courage (*see* METEMPSYCHOSIS), and trial by ordeal of battle is practised. A bamboo-headed spear is still used in Ceram.

ALGAE. The algae comprise seaweeds, pond-scums, and a great variety of microscopic plants inhabiting fresh and salt waters in countless numbers. Many are found in or on the soil or on rocks and tree-trunks, and no region of the earth is devoid of them (*see Occurrence and Distribution*, p. 601). The Latin *alga* means seaweed and only later acquired its present wider meaning. The algae belong to the lowest division (Thallophyta) of the vegetable kingdom, and are distinguished from the majority of higher plants by their simple reproductive organs and by the fact that their vegetative body as a general rule has a relatively simple construction; it is usual to speak of the body of the bigger algae as a *thallus*. All algae are holophytic; *i.e.*, they contain chlorophyll which enables them to use the energy of sunlight and to build up in the process of photosynthesis the organic compounds forming their body from carbon dioxide, water, and other simple substances. This distinguishes them from the fungi, the other subdivision of the Thallophyta. On the other hand it is very difficult to separate the algae from those groups of Flagellata which are holophytic (*see Phylogeny*, p. 600, and PROTOPHYTA). Most algae can only be studied with the help of a microscope, although no very high powers are necessary to make out the essential features.

STRUCTURE AND REPRODUCTION

The algae exhibit a diversity of form not found in any other group of plants, ranging from one-celled organisms through manifold colonial types to simple or branched rows of cells (filaments) and onwards to elaborate massive growths attaining dimensions and complexities of structure that sometimes vie with those of flowering plants. The group is of great interest to the evolutionist, because it affords all possible stages in the evolution of a plant-body.

Unicellular and Colonial Forms.—Simplest are the unicellular individuals which are commonly spherical or oblong and usually enveloped by a firm cell-wall. The protoplasm of such cells resembles that of other plants in possessing a nucleus and one or more chromatophores containing chlorophyll and other pigments. Many unicellular algae (*e.g.*, *Chlamydomonas*, fig. 1, A) move freely with the help of delicate prolongations of the protoplasm, the cilia, which arise usually at the front end and

push the cell through the water by a movement somewhat like that of the arms of a human being whilst swimming. Motile individuals may be aggregated into colonies of diverse shape (*Pandorina*, fig. 1, B; *Volvox*, fig. 2, A), moving by the united action of all the cilia. The cells of these algae are often provided with a red streak or dot, the eye-spot, and two or more pulsating vacuoles near the front end, structures which they have in common with many unicellular animals.

Multiplication is effected by successive divisions of the protoplasm into 2, 4, 8, etc., parts, which secrete new membranes and gradually acquire all the parent's characteristics; in the colonial types each cell may divide in this way to produce a new colony. Reproduction is often preceded by withdrawal of the cilia and cessation of movement. In numerous unicellular and colonial algae this motionless state is the usual one. Naked motile cells (*zoospores*, *see* below) may be formed as a means of reproduction (*Chlorococcum*) or the power of movement is altogether suppressed and the new individuals are motionless from the first (*e.g.*, *Chlorella*, fig. 1, C and the colonial *Scenedesmus*, fig. 1, D). At times the progeny of a motile unicell (*e.g.*, *Chlamydomonas*) fail to acquire cilia and remain encased within the mucilaginous membrane of the parent; this may happen to successive generations and result in the formation of large jelly-like masses, from which the contained cells may ultimately escape as swimmers. In some algae (*Tetraspora*, *Gloeocapsa*, fig. 1, E) this palmelloid state is the normal one. There is little doubt that the motionless have in most cases evolved from motile types in one or other of the ways just indicated.

Filamentous Forms.—Many pond-scums and small seaweeds are filamentous, consisting sometimes of a simple row of similar cells (*Ulothrix*, fig. 1, F; *Tribonema*, fig. 2, F), although in most there is repeated branching; all the branches may be alike (*Ectocarpus*, fig. 1, H) or some may stand out as main axes bearing smaller lateral branches, which often arise in bunches (*e.g.*, *Batrachospermum*, fig. 4, A). Filamentous algae commonly reproduce by *zoospores*, *i.e.*, naked ciliated bodies formed (with or without previous division) from the protoplasm of ordinary (fig. 1, G) or specially enlarged (fig. 3, A) cells and liberated through a hole in the wall. The close similarity of these zoospores to the motile individuals of the same class warrants the assumption that the filamentous algae have evolved from such motile unicells, the method of their origin being illustrated by the way in which the zoospores proceed to produce new filaments. Their movements may continue for half an hour up to two or three days; but ultimately they settle down on some firm substratum, withdraw the cilia, and secrete a membrane. The end in touch with the substratum spreads out into a lobed holdfast (fig. 1, P), whilst the other rapidly lengthens and divides to form the thread, which in quiet water soon breaks away from its holdfast and floats freely. In rivers or in the sea the attachment is more permanent. In all filamentous forms, however, propagation by detached pieces of the threads (fragmentation) is frequent.

In many filamentous algae the thallus is composed of two branched systems, the one creeping upon some substratum and bearing the other which floats out into the water (*e.g.*, *Stigeoclonium*, fig. 2, D, and many of the simpler seaweeds). By suppression of the projecting system purely prostrate forms result, in some of which the branching is so dense that the threads fit together to form one-layered discs (fig. 2, E). All these and many other smaller algae are commonly found attached to larger ones or to aquatic flowering plants; *i.e.*, they are *epiphytes*.

Every cell of the simpler filamentous algae can enlarge and divide to form new cells, thus leading to a lengthening of the thread, but in the branched types such growth is often restricted to definite regions (*e.g.*, at the bases of the hair-like tips in many brown seaweeds, fig. 1, H) or confined to the end cell of each branch (*Cladophora*).

Structure of Seaweeds.—Such apical growth is usual in many filamentous seaweeds, most of which possess a more elaborate structure than the freshwater forms. The segments cut off from the apical cell often divide lengthwise as well as crosswise, so that the filament consists of several longitudinal series of cells which

commonly show a definite arrangement in tiers (e.g., *Sphacelaria*, fig. 1, 1). In the older parts of many filamentous seaweeds a further complication of structure results from the outgrowth of cortical threads, either from the basal cells of the branches (*Batrachospermum*, fig. 4, A') or merely from the superficial cells of the thread itself; these apply themselves closely to its surface and form a dense small-celled investment which may become many layers thick and completely hide the original thread.

The thallus of some seaweeds is built up by the close juxtaposition of many filaments. In such there is a central cord or axis consisting of numerous longitudinal threads which are often more or less intertwined and which bear large numbers of short branches, projecting approximately at right angles and uniting to form a surface of varying degrees of compactness (fig. 1, J). Many of these forms appear to the naked eye as rather thick little branched threads (*Nemalion*, *Castagnea*), but seaweeds of quite a different outward shape may possess the same construction.

Many seaweeds are flattened and leafy, but such forms have doubtless originated from filamentous types in the course of evolution. Some in fact begin life as a simple filament and the derivation from a branched thread may even be decipherable in sections of the mature alga. In *Ulva* (sea lettuce) and *Porphyra* the thalli are thin flat sheets composed of uniform cells without localized growth, but in carrageen (fig. 4, F) and the brown *Dictyota* there are special apical cells at the tips of the numerous flattened branches and these have a firmer texture, being composed of three or more layers of cells, the inner ones usually much larger than the outer (see fig. 3, J).

The most complex structure is found in the large brown seaweeds (Laminariales and Fucales). Here it is usually possible to distinguish stalk and blade (e.g., *Laminaria*, fig. 1, K) and the latter may show a central thickened region (midrib) as in the Bladderwrack. In *Lessonia* (fig. 3, G) the stalk may have the thickness of a man's thigh and bears at its apex numerous long blades, the whole resembling a small tree. The bulky thalli, which are often several yards from base to apex, are attached by elaborate holdfasts, fingerlike in Laminariales, suckerlike in Fucales, and often clinging tenaciously to the rocks. In sections of the stalks it is easy to distinguish a central medulla of very irregularly arranged and prevalently elongate cells serving as a strengthening cord and for the conduction of food-substance, a wide cortex of broader cells storing food-reserves, and a superficial assimilatory region of small cells with many chromatophores. The surface cells at times divide abundantly and thus lead to the progressive increase in thickness of the stalk. The most striking of these large forms is *Sargassum* (fig. 1, L), where the cylindrical stalks bear numerous leafy outgrowths provided with a midrib and bearing in their axils small branch-systems, either terminating in air-bladders or containing reproductive organs.

Most algae possess a slimy feeling owing to the mucilaginous quality of the cell-walls. This feature is specially pronounced in the larger seaweeds and particularly in those inhabiting the stretch of shore between tidelevels, where the capacity of mucilage to absorb and retain moisture no doubt constitutes a protection against drying.

Chromatophores.—The chlorophyll and other pigments that give different algae their distinctive colours are (except Myxophyceae, see below) contained in special chromatophores, which are of diverse shape and size and in some groups are of great importance for the identification of genera and species. They are usually parietal (i.e., located in the protoplasm just beneath the cell-walls, fig. 1, C and F), but in some green and red forms they are axile (i.e., in the centre of the cell, fig. 2, G). In green algae the cells commonly contain only one or a few large chromatophores, but in the other classes they are usually more numerous and simpler in form, often appearing as little lens-shaped bodies (fig. 2, P). Embedded in the substance of the chromatophore are often found conspicuous rounded bodies, the *pyrenoids* (fig. 1, A and F), which consist of protein. Their exact purpose is not yet clear. In the green algae the pyrenoids are usually surrounded by starch, so that treatment with iodine renders them very conspicuous.

Asexual Reproduction.—The purely vegetative multiplica-

tion of algae by fragmentation of the threads has already been mentioned and fragments of the thallus may even, in the more elaborate forms under suitable conditions, give rise to a new organism. In most algae, however, a more specialized method (asexual reproduction), involving the liberation of spores formed from the entire or subdivided protoplasm of the cells, occurs at certain times. Many produce ciliated zoospores (cf. above) which are always without a wall and vary in character in the different classes; in more advanced types (e.g., *Ectocarpus*, fig. 3, A) they are produced within larger cells (sporangia), often differing in shape from the others and sometimes restricted to definite parts of the body. The zoospores may at times fail to develop cilia, secreting a thin wall already prior to their liberation. Such aplanospores are clearly zoospores which have lost the power of movement, and possibly illustrate the mode of origin of the motionless spores found in many algae lacking zoospores altogether. Thus, in most red seaweeds the sporangia produce four such motionless spores (tetraspores, fig. 4, C).

Sexual Reproduction.—A large number of algae exhibit sexual reproduction and all stages in its evolution may be found within the group. In the simplest cases (e.g., *Ulothrix*, *Ectocarpus*) the sexual cells or gametes, except for smaller dimensions, essentially resemble the zoospores and are formed in the same way. After a period of movement they meet in pairs and gradually fuse (fig. 1, Q) their nuclei fusing at the same time. Often the fusing gametes are identical in all respects (isogamy), although probably always derived from distinct individuals. In other cases there are two kinds of gametes (anisogamy) which may either merely differ in behaviour, one coming to rest before fusion occurs (e.g., *Ectocarpus*), or more commonly the passive gamete is larger and more liberally supplied with chromatophores than the other (e.g., *Cutleria*, fig. 1, O).

The advanced algae exhibit greater differences between the sexual cells (oogamy), the female or ovum being large, motionless, and provided with abundant chromatophores, the ciliated male or spermatozoid minute, actively motile, and consisting mainly of a nucleus with a thin covering of protoplasm (e.g., *Vaucheria*, *Fucus*). Ova and spermatozooids are formed within special cells (sexual organs) of diverse types; the oogonia (fig. 1, M and N; 2, J) harbouring one or, more rarely, several ova, are larger than the antheridia, which mostly produce many spermatozooids of a pale colour (often yellow). As a general rule the ovum remains inside the oogonium whose wall develops an aperture through which the spermatozoid swims and fuses with (i.e., fertilizes) the ovum. The red seaweeds have motionless male cells which are drifted by currents to the female organs (fig. 4, B). The unicellular sexual organs of most algae offer a sharp contrast to those of Bryophyta (liverworts and mosses).

The sexual cells are always devoid of a membrane, but after fusion the zygote soon secretes a thin wall and in seaweeds immediately proceeds to divide to form a new individual; in freshwater algae, however, the membrane is usually thick and a resting spore, often with yellow or red contents, results. Sexual cells may occasionally develop into new individuals without fusion, but in the oogamous types this is only rarely observed (*Cutleria*, *Chara*).

The Life-cycle.—The marked polymorphism, formerly ascribed especially to the simpler algae, is now disproved. A few occasionally assume forms differing considerably from the normal. Thus, various filamentous algae at times pass into a palmelloid condition, resembling that described for *Chlamydomonas*.

The alternation between sexual (gametophyte) and asexual (sporophyte) individuals, which is such a prominent feature of the life-cycle of the higher plants, is exhibited in varied ways among the algae. The green forms mostly show no clear alternation, the sexually formed spores, on germination, usually producing a few (often four) zoospores or aplanospores which form the new individuals. In *Coleochaete* there is more extensive division of the spore, a mass of 16 or 32 cells being formed, each of which can produce a new plant. This mass of cells is sometimes called a sporophyte, the ordinary *Coleochaete*-disc (fig. 2, E) bearing the sexual organs, being the gametophyte; but since reduction in chromosome-number (see CYTOLOGY) occurs at the first

FIG. 1.—STRUCTURE AND REPRODUCTION OF UNICELLULAR, COLONIAL AND FILAMENTOUS FORMS

ALL EXCEPT K AND L CONSIDERABLY MAGNIFIED

Algae, the botanical group which includes seaweeds, pond-scum, and a great variety of microscopic plants, inhabit fresh and salt water, are found on or in the soil and on rocks and tree trunks in every region of the world. They comprise, with the fungi, the lowest division of

the vegetable kingdom (Thallophytes). Algae contain a green substance called chlorophyll which enables them in the presence of sunlight to build up their bodies from carbon dioxide, water and other simple substances. Fungi, having no chlorophyll, cannot do this

division in the fertilized ovum (as in all green algae), the sporophyte lacks the double chromosome-number usually regarded as characteristic of it. The simpler red seaweeds (Nemalionales) show the same features, the sporophyte here being represented by a bunch of threads that sprout out from the female organ after fertilization.

Among brown seaweeds many instances of alternation are known, where the asexual and sexual individuals differ in their chromosome-number in the same way as in higher plants. In some (*Pilayella*, *Dictyota*) the two generations are identical, except for this and for the kinds of reproductive structures they bear (homologous alternation). In *Laminaria* and its allies, however, they are sharply distinct (antithetic alternation), the sporophyte being an elaborate plant (fig. 1, K), the gametophyte a filament of microscopic dimensions (fig. 3, H). In *Cutleria*, on the other hand, the ribbon-like thalli of the sexual individuals are more conspicuous than the flat crusts of the asexual (fig. 3, F). Certain facts appear to indicate that, even in these cases, the two generations may originally have been alike. Most red seaweeds (except Nemalionales) show a true homologous alternation, the sporophyte with tetraspores (fig. 4, C) and the gametophyte bearing sexual organs closely resembling one another; but there is the curious complication that the fertilized ovum gives rise to bunches of threads which produce carpospores, and it is from these that the tetrasporic plants arise. In these forms there are thus two different sporophytes arising from one another, the second producing the gametophyte.

CLASSIFICATION OF ALGAE

The various classes of algae are essentially distinguished by the pigments in their chromatophores, the kinds of reserve-foods stored after photosynthesis, and the nature of their reproductive structures. They are:—I. Isokontae (Chlorophyceae), the green algae; II. Charales, the stoneworts; III. Heterokontae, the yellow-green algae; IV. Bacillariales (*q.v.*), the diatoms; V. Phaeophyceae, the brown algae; VI. Rhodophyceae, the red algae; VII. Myxophyceae (Cyanophyceae), the blue-green algae. There are, however, various groups of Flagellata (*e.g.*, Chrysomonadineae, Peridinieae) which include some algal forms and should no doubt rank as algae (*see* PROTOPHYTES), but the scope of this article is restricted to the above classes, the majority of whose members are true algae.

Green Algae.—I. The ISOKONTAE (CHLOROPHYCEAE) include a wide range of forms which are mainly freshwater or terrestrial, though most Siphonales are marine. They are readily recognized by their dark green colour and the storage of starch (coloured blue by iodine). The chromatophores are here chloroplasts containing the same pigments (chlorophyll, etc.) as in higher plants, though often possessing an elaborate shape and frequently provided with pyrenoids surrounded by starch. The motile stages (including zoospores and gametes) bear equal cilia (often two or four) attached to the front end. Cellulose frequently predominates in the cell-wall. The majority of Isokontae are isogamous and the gametes, except in the few oogamous types, are produced in the ordinary cells.

The motile forms are classed as VOLVOCALES, which include the unicellular *Chlamydomonas* (fig. 1, A) and various colonial types such as *Pandorina* (fig. 1, B), *Eudorina* (with 32 spherical cells arranged round the edge of a mucilage-sphere), and *Volvox* (fig. 2, A), where the colonies are composed of several thousand cells, all four often abundant in small pools. In *Volvox* the production of new colonies is restricted to special larger cells, and both this genus and *Eudorina* are oogamous. The Volvocales also include palmelloid forms, such as *Tetraspora* whose delicate green mucilage-masses, with the cells in groups of four, are common attached to water-plants in spring.

The motionless CHLOROCOCCALES (=Protococcales) comprise *Chlorococcum* (on damp soil), *Chlorochytrium* with large cells inhabiting the air spaces of the duckweed, and *Trebouxia* (= *Cystococcus*) which is found in many lichens and possesses an axile chloroplast. These three unicellular forms reproduce by zoospores, but the latter are lacking in *Chlorella* (fig. 1, C), which

is common in contaminated waters (*e.g.*, sewage) and also occurs as "green cells" in various animals (*Hydra*, etc.), and *Micracetium* (fig. 2, B), whose free-floating cells bear long delicate bristles. Many are colonial, *e.g.*, *Scenedesmus* (fig. 1, D), the flat plates of *Pediastrum* with marginal cells produced into short processes, and the "water-net" (*Hydrodictyon*, fig. 2, C).

The ULOTRICHALES include unbranched filamentous forms, such as *Ulothrix* (fig. 1, F), not uncommon in streams, and *Hormidium*, forming a weft on damp soil, both with a curved parietal chloroplast in their cells, as well as *Prasiola* which is terrestrial and has an axile chloroplast. The filaments of the last commonly undergo extensive division by longitudinal walls, resulting in leafy expanses which may be very abundant where organic matter abounds (*e.g.*, near the penguin rookeries in the Antarctic). Somewhat similar are the flat sheets of the sea lettuce (*Ulva*) which are common objects on the sea-shore; but here the chloroplast is parietal. The Cladophoraceae, which are usually branched, have large cells containing many nuclei and for this reason are often referred to the Siphonales. *Cladophora*, with thick cell-walls and an elaborate net-like chloroplast is abundant in well aerated pools and streams, and also occurs on rocks in the sea.

In the CHAETOPHORALES the thallus is differentiated into prostrate and projecting systems, well seen in *Stigeoclonium* (fig. 2, D), where, as often in this group, the branches terminate in long hairs. *Draparnaldia*, which like *Stigeoclonium* is frequent in slow-moving waters, differs in possessing distinct main axes with large clear cells having a scanty chloroplast, while the bunched laterals are deep green. *Trentepohlia*, found as orange tufts on rocks and trees especially in hilly country, has its cell-sap coloured by haematochrome and possesses special zoosporangia. The group also includes many prostrate epiphytes, *e.g.*, *Aphanochaete* (frequent on *Cladophora* or *Oedogonium*) which is markedly anisogamous, and *Coleochaete* (fig. 2, E), whose cells bear curious sheathed hairs and which is oogamous. The common unicellular *Pleurococcus*, found on tree-trunks, etc., is probably an extremely reduced member of this group.

The OEDOGONTALES with big cells containing a netlike chloroplast, reproduce abundantly by large zoospores which bear a ring of numerous cilia and are formed singly in the cells. They include the unbranched *Oedogonium* and the richly branched *Bulbochaete*, where each cell bears a long hair with an inflated base. These are oogamous forms, often producing their flat antheridia in special "dwarf-male" filaments which are found attached on (fig. 1, M) or near the swollen oogonia.

The CONJUGATAE, which are widely distributed in freshwater, are distinguished by their elaborate chloroplasts with prominent pyrenoids, by lacking asexual reproduction, and by a peculiar sexual process (conjugation) in which the gametes are constituted by the contents of the ordinary cells. They comprise a filamentous series (Zygnemales), including *Spirogyra* (with spiral chloroplasts) (fig. 2, F) and *Zygnema* (with two star-shaped chloroplasts in each cell), but are more extensively represented by the unicellular Desmids. The cells of the latter exhibit a great variety of beautiful and symmetrical shapes, and are commonly divided by a median constriction into two semicells, each harbouring one or two complex chloroplasts; examples are furnished by *Closterium* with semilunar cells, *Cosmarium* (fig. 2, G), and *Staurastrum* (fig. 2, I), where the semicells are produced in two or more arms. A few Desmids form threadlike colonies. During conjugation in the Zygnemales, opposite cells of two parallel threads become connected by tubes (fig. 2, F), whereupon the protoplasm of the one glides over into that of the other and fuses with it to form a zygospore (*Spirogyra*), or the protoplasmic masses meet in the tube and form the zygospore there (often in *Zygnema*). In Desmids the protoplasts escape from two adjacent individuals and fuse to form a zygospore which lies between the empty halves of the parent cells (fig. 2, H). Both Oedogoniales and Conjugatae are highly specialized.

The SIPHONALES are coenocytic, *i.e.*, their large multinucleate bodies possess few or no septa. The only freshwater form, *Vaucheria*, shows this clearly, its branched, rather coarse filaments containing numerous nuclei and lens-shaped chloroplasts in the lin-

FIG. 2.—THE GREEN AND YELLOW-GREEN FORMS, THE MORE COMMON FRESHWATER AND TERRESTRIAL ALGAE

The chief groups of Algae are distinguished by the pigments they contain. The Green Algae are the simplest having no other pigment than the green chlorophyll. Green Algae are mainly freshwater or

terrestrial and are recognized by their dark green colour and storage of starch. The Yellow-green Algae, mainly found in freshwater, are distinguished by absence of starch and storage of oil

ing protoplasm which surrounds a huge and continuous vacuole. The marine forms mostly show a more elaborate structure. Thus, the *Caulerpas* of warmer seas have a thallus differentiated into a creeping stem (up to a foot long) anchored by branched rootlets and bearing leaflike outgrowths, which in their varied form and arrangement simulate the shoots of diverse higher plants (fig. 2, κ). Other Siphonales (Codiaceae) resemble certain brown and red seaweeds in having a body built up of numerous closely placed and often intertwined threads like those of *Vaucheria*, e.g., *Codium* and *Halimeda*, the latter with a flat segmented thallus encrusted with lime. In another family (Dasycladaceae) an erect main axis bears compact whorls of branches between which there is often extensive deposition of carbonate of lime; one of the most striking forms is the Mediterranean *Acetabularia* (fig. 2, λ), where the whole plant is encased in lime. Many similar calcareous forms are known as fossils. The Siphonales are mostly isogamous or anisogamous, producing their gametes in special gametangia; but *Vaucheria* is oogamous with antheridia and oogonia situated side by side on the filament (fig. 2, j).

Stoneworts.—II. The CHARALES (stoneworts), which grow submerged in fresh and brackish waters, are so complex, especially in their reproductive organs, that they can have but a very remote relationship with the green algae. The slender cylindrical axes bear whorls of short branches (often called leaves), which are separated by long internodes and produce occasional branches in their axils. The popular name is due to the considerable deposition of lime in the superficial membranes. All the cells contain numerous small chloroplasts. The segments cut off from the apical cell divide into an upper half forming a node and a lower half forming an internode; the latter lengthens greatly but remains undivided, while the node becomes segmented by vertical walls, the peripheral cells growing out into "leaves" which, except for their limited growth, show the same structure as the "stems." In *Chara* threads sprout out from the lowest nodes of the leaves and closely invest the stem, but in *Nitella* this cortex is lacking.

In spite of prolific vegetative reproduction sexual organs are formed abundantly. They usually arise close together at a node (fig. 2, μ). The large oogonia are completely invested by five green spiral threads whose tips form a symmetrical group (corona) at the apex. The spherical antheridium has a wall composed of eight somewhat curved "shields" which at maturity acquire a yellow or red colour; to the middle of the inner (concave) surface of each shield is attached a rod-shaped manubrium carrying a number of long coiled threads, in each compartment of which a spermatozoid is formed. At maturity the whole structure falls to pieces and the spermatozooids are set free. The fertilized ovum acquires a thick wall and rests prior to its germination, which is complex.

Yellow-green Algae.—III. The HETEROKONTAE are mainly found in freshwater, though the unicellular *Halosphaera* is of widespread occurrence in marine plankton. They are distinguished by the yellow-green colour, the absence of starch, and the storage of oil. The chloroplasts contain much xanthophyll (blue with nitric acid), are commonly disc-shaped, and never possess pyrenoids. The motile stages are provided with two very unequal cilia attached at the front end (fig. 2, ν). The cell-walls are often rich in pectic substances. Sexual reproduction is rare and always isogamous, and both zoospores and gametes are formed in the ordinary cells.

The Heterokontae, though represented by far fewer genera and species than the Isokontae, exhibit much the same range of form. The motile unicell is illustrated by the rare *Chloramoeba* (fig. 2, ν), whose cells are without a wall, but there are no motile colonies. Various palmelloid types are known, the commonest being *Botryococcus*, an abundant plankton form, in which the mucilage of the rather irregular colonies is often so dense that the contained cells are difficult to detect. Motionless unicells are seen in *Chlorobotrys* (a rare moorland form), *Halosphaera*, and the multinucleate *Ophiocytium* (fig. 2, ο), which is common in stagnant pools. Its curved cells have a wall composed of two very unequal pieces, the smaller becoming detached as a lid when zoospores or aplospores are to be liberated. *Tribonema* (= *Conferva*, fig. 2, ρ),

a common freshwater form, has filaments with long narrow cells which have a wall composed of two overlapping pieces and many disc-shaped yellowish green chloroplasts. The only siphonous form is *Botrydium* (fig. 2, q), not uncommon on damp mud; when the latter dries, all the protoplasm withdraws into the underground rhizoid and divides into a number of thick-walled cysts.

Diatoms.—IV. BACILLARIALES, which are abundant in all kinds of situations, are a specialized class of unicellular and colonial forms whose silicified wall is composed of two overlapping pieces. They are dealt with in a separate article.

Brown Seaweeds.—V. PHAEOPHYCEAE (brown seaweeds) are more especially characteristic of the colder seas. Their colour is due to fucoxanthin which accompanies the usual pigments in the chromatophores; there are generally several of the latter of varied shape in each cell. The products of photosynthesis are fucosan (red with vanillin dissolved in concentrated hydrochloric acid) and fat; opinions differ as to the nature of the former. The zoospores are formed in special sporangia and, except in the most advanced oogamous forms, the sexual organs are multicellular (fig. 1, η). The zoospores and gametes have two cilia attached to one side of the body, one directed forwards, the other backwards (fig. 3, β); near the attachment of the cilia there is a conspicuous eye-spot.

The simplest Phaeophyceae are the ECTOCARPALES, the palmelloid forms previously included in this class being now referred to the Chrysophyceae (see PROTOPHYTA). *Ectocarpus*, whose brown tufts or tresses are commonly seen in rock-pools, is like a brown *Stigeoclonium* having prostrate and projecting systems; each branch of the latter grows by the division of a series of flat cells situated below the terminal hair (fig. 1, η). Numerous zoospores (fig. 3, β) are produced in large (unilocular) sporangia (fig. 3, α), while the gametes which are quite similar arise singly in the compartments of elongate gametangia (plurilocular sporangia, fig. 1, η). In *Pilayella* sporangia and gametangia are interspersed between the ordinary cells. The gametes, though alike in form, may differ in behaviour, some soon ceasing to move and being sought out by others which retain their activity. In *Giffordia*, with two kinds of gametangia, there is marked anisogamy. The sexual individuals of *Pilayella* (see *Life-cycle*, p. 592) are found in spring, the asexual in summer; both bear plurilocular sporangia, those of the latter liberating zoospores which give rise to a new asexual generation without the intervention of a sexual one.

Many Ectocarpales are far more complex, though all can be related to *Ectocarpus*. A few examples must suffice. *Desmarestia* (fig. 3, c) has main axes, from 1½–4 feet long, bearing numerous short stiff branches which in winter and spring end in feathery tufts, but in summer are bare. The large cells of the axis (fig. 3, δ) each produce a pair of short branches, from the lowest cells of which threads grow out in profusion and become matted together to form a wide "cortex" which grows very thick in the older parts. The branched gelatinous threads of *Castagnea* and the irregular jellylike lumps of *Leathesia*, common on larger seaweeds, are built up of numerous filaments in dense juxtaposition at the surface, but more loosely arranged in the interior. Of a different type are the bladderlike thalli of *Asperococcus* and the long occasionally constricted tubes of *Scytosiphon*, which arise by longitudinal division in the cells of the primary thread followed by the development of a central air-cavity. Many Ectocarpales (*Elachista*, *Myriotrichia*) form small epiphytic cushions or tufts.

The cylindrical threads of the SPHACELARIALES possess a prominent apical cell which cuts off segments parallel to its base (fig. 1, ι). These, without further elongation, divide abundantly and often very regularly by transverse and longitudinal walls; the older parts are, however, often covered by a dense small-celled cortex. The numerous branches mostly remain quite short and by their arrangement determine the habit of the plant. *Sphacelaria* is a bushy form, rarely exceeding one or two inches in height with feathery arrangement of the branches. *Cladostephus* is larger and has whorled branches. The former multiplies abundantly by means of triangular or three-armed propagules. The reproduction of Sphacelariales resembles that of Ectocarpales; some are anisogamous like *Giffordia*.

FIG. 3.—BROWN ALGAE, MORE ESPECIALLY CHARACTERISTIC OF THE COLDER SEAS

The Brown Algae have a yellowish to brown pigment in addition to the chlorophyll, which gives them various shades from olive to yellow and brown. There are a dozen or more orders in this group, the

largest of which are the Ectocarpales which consist of very simple forms of filaments, the Laminariales or kelps, and the Fucales which include rock weeds and Sargassum

Cutleria, the principal genus of CUTLERIALES has a branched ribbon-like thallus, several layers of cells thick, the ultimate segments ending in a fringe of hairs, each exhibiting at its base a dividing zone like that of *Ectocarpus*. The dark dots on the unisexual thalli correspond to groups of hairs bearing gametangia (fig. 3, E), the female having large deep brown compartments, the male small pale yellow ones. Both gametes are motile (fig. 1, o). After fusion they produce a flat crustlike thallus (*Aglaozonia*-stage, fig. 3, F), several layers of cells thick and bearing a dense row of sporangia on the upper surface. The zoospores ordinarily give rise to the *Cutleria*-plant, but this regular alternation does not always occur, either generation being capable of reproducing itself.

Oogamous Forms.—The remaining brown seaweeds are oogamous. Among these the LAMINARIALES alone possess zoospores which are produced in densely crowded sporangia occupying the surfaces of the blades. This group includes the largest seaweeds, which are often very elaborate in form and structure. One of the simplest is *Chorda filum*, whose unbranched whiplike thalli may be several yards long, whilst barely a quarter of an inch thick. In *Laminaria* there is a long stalk terminated by a blade which is entire (*L. saccharina*) or divided into fingerlike segments (e.g., *L. digitata*, fig. 1, K). New blades arise periodically by a gradual widening at the top of the stalk, the old blade being slowly destroyed by the waves. The divided blades of *Laminaria digitata*, etc., arise by the formation in the new growth of several long slits which ultimately reach the free edge. This explains the development of such an elaborate form as *Lessonia* (fig. 3, G), the young stages of which resemble a *Laminaria* with a simple blade; by progressive splitting and the development of separate stalks to the segments the large treelike growth (10–12 ft. high) ultimately arises. *Macrocystis*, the giant of the southern seas, develops in much the same way. Here the slender stalk, which is up to 60 yd. long, trails out from its attachment to the rocks to the surface of the water, where it bears two long rows of narrow blades, floating with the help of air-bladders at their base. *Nereocystis*, which is like a huge *Laminaria digitata* and occurs on the Pacific shores of America, has an immense air-bladder at the top of the stalk. *Alaria*, a much smaller form whose blade has a midrib, has narrow outgrowths on the stalk to which the sporangia are confined. Similarly, in *Macrocystis* the latter are found on simple shoots arising from the base of the stalk.

The complex internal structure has already been described; of special interest are the sieve-tubes, closely resembling those of higher plants, found in the inner cortex of *Macrocystis* and *Nereocystis*. The medulla in all cases contains numerous "trumpet-hyphae" (fig. 3, I) with a marked dilation at the septa which show a sieve-like pitting.

The gametophytes are microscopic filaments bearing either antheridia producing a single, almost colourless, spermatozoid (fig. 3, H), or oogonia with a single ovum.

Dictyota, which is typical of the DICTYOTALES, has a forked band-shaped thallus growing by an apical cell. The asexual individuals bear at intervals spherical sporangia, each producing four motionless spores. These give rise to male or female individuals. Oogonia and antheridia are formed in compact groups on the surface, the former (fig. 3, J) unicellular and producing each one ovum, the latter of the usual septate type; the male cells have only a single apical cilium. In *Padina*, which is rarer, the thalli are fan-shaped with an inrolled margin and exhibit a prominent concentric zoning.

The FUCALES, although not nearly so large, are quite as complex as the Laminariales. There is no asexual propagation, but sexual reproduction is very prolific. The sexual organs are borne amidst numerous hairs on the inner surface of round cavities (conceptacles) (fig. 3, K), which appear as swellings on the thalli and open to the exterior by a small aperture. The large oogonia (fig. 1, N) produce eight (*Fucus*), four (*Ascophyllum*), two (*Pelvetia*), or only one ovum (*Himanthalia*), while the antheridia, borne in large numbers on branched hairs (fig. 3, L), form minute spermatozooids. Male and female organs occur on distinct individuals or, more rarely (*Pelvetia*) in the same conceptacle. The gametes

are extruded from the conceptacles in a drop of mucilage during low tide, and fertilization takes place when the sea returns. The fertilized ovum grows direct into a new plant. The conceptacles are generally restricted to the tips, although *Fucus* and others have similar, but smaller, barren conceptacles scattered over the whole thallus.

In the bladderwrack (*Fucus*) the flat segments have a thick midrib which persists as a stalk in the older parts of the plant; several species have paired air-bladders. *Pelvetia*, which is much smaller, has narrow branches which are deeply channelled, while the irregularly swollen tips render fertile plants very conspicuous. The long straplike thalli of *Ascophyllum*, dilated at intervals by air-bladders, bear numerous short branches which arise from marginal slits and in the upper parts of the plant contain the conceptacles. In *Himanthalia* the thallus is roughly of the shape of a top and about an inch across, but periodically the upper surface gives rise to a forked straplike outgrowth, as much as a yard long and studded with conceptacles. The distribution of these forms on the sea-shore is dealt with below. *Sargassum* (fig. 1, L) has already been described. The internal structure of Fucales is similar to that of Laminariales, though somewhat simpler.

A seventh group of brown algae, the Tilopteridales, are rare and too incompletely known to be considered here.

Red Seaweeds.—VI. RHODOPHYCEAE (red seaweeds) are a highly specialized class, mainly confined to the sea. The marine forms are usually coloured various shades of red or purple, while the freshwater ones are often bluish. The chromatophores, of which several are found in each cell, contain a red (phycoerythrin) and a blue (phycocyanin) accessory pigment, and the different colours are due to the varied proportions in which these two pigments occur. Pyrenoidlike bodies are frequently found in the less specialized forms. The product of photosynthesis consists of small doubly refractive granules of Floridean starch (brownish or reddish with iodine). The thick, mucilaginous cell-walls are usually provided with conspicuous pits connecting the protoplasm of adjacent cells. No red seaweed has any motile reproductive cells.

The simple BANGIALES, whose cells have an axile star-shaped chromatophore and are without pits, include *Bangia*, with unbranched threads whose cells are longitudinally divided, and *Porphyra*, with a flat *Ulva*-like thallus, both marine. Their relation to other red algae is not clear. They reproduce asexually by liberation of the contents (monospores) of ordinary cells, while their sexual reproduction is not unlike that of the Nemalionales (see below).

The large remainder of the red algae, styled FLORIDEAE, are classed in four groups distinguished by the events following upon fertilization. Their thallus exhibits diverse structure, but growth is usually apical. *Callithamnion*, one of the simplest forms, consists merely of richly branched threads with elongate cells. Many other Florideae are filamentous, though with a more elaborate structure. Thus in *Ceramium* the threads show a characteristic banding (fig. 4, D), due to the formation of a small-celled cortex around the upper end of each principal cell. In *Polysiphonia* the segments of the apical cell divide with great regularity by longitudinal walls, forming characteristic tiers with a deeply coloured central cell shimmering through the peripheral ones. *Batrachospermum*, the "frog-spawn alga," found in slowly moving streams, has soft threads resembling a string of beads, each constituted by a whorl of branches (fig. 4, A); the large cells of the main axes are overgrown by cortical threads.

In *Nemalion* or *Furcellaria* the threads are coarser and, like *Codium* or *Castagnea*, composed of numerous filaments in more or less dense aggregation (fig. 1, J). *Corallina* shows the same structure, but here the pink barrel-shaped segments are densely encrusted with lime and separated by uncalcified joints, where the central threads bear no lateral branches. Closely related are *Lithothamnion* and *Melobesia*, with strongly calcified encrusting thalli which are specially common in the warmer seas and often assist in the building of coral-reefs. Such forms are also known as fossils.

Many Florideae have a flattened thallus which may be exten-

FIG. 4.—TYPES OF MARINE RED ALGAE AND OF BLUE-GREEN FRESHWATER ALGAE

The Red Algae have a red pigment in addition to the chlorophyll; this gives to their graceful and often delicate bodies beautiful tints and shades of red and purple. They are regarded as the most beautiful of all the marine algae. The Blue-green Algae are a very distinct class,

probably an ancient group that has retained primitive characteristics. Their prevalent colour is blue-green, but other tints, such as violet and red are not uncommon. They are of wide distribution, especially in freshwater and terrestrial habitats

sively branched, e.g., carrageen (*Chondrus crispus*, fig. 4, F) and *Gigartina*, the latter with numerous teatlike outgrowths which harbour the fruits. Some of the most beautiful forms belong to *Delesseria* (fig. 4, G).

Reproduction of Red Seaweeds.—The sexual organs are usually formed on the lateral branches, the rounded antheridia in groups, and the female organs (carpogonia) singly (fig. 4, B). Each carpogonium is flask-shaped and prolonged into a narrow neck (trichogyne), the ovum occupying the swollen base. Each antheridium produces a single motionless spermatium, which is conveyed by chance currents to the trichogyne. After solution of the wall the contents of the spermatium pass through the trichogyne to fuse with the female cell. The consequences of fertilization vary in the different groups.

In the NEMALIONALES (incl. *Batrachospermum* and *Nemalion*) numerous short sporogenous threads sprout from the carpogonium (cf. fig. 4, A'), their end-cells liberating naked carpospores which produce a new individual. These sporogenous threads are sometimes regarded as a sporophyte (see above). Asexual reproduction in the Nemalionales is either lacking or effected by monospores formed singly in spherical sporangia.

The remaining Florideae reproduce asexually by tetraspores developed in tetrasporangia which either project freely (fig. 4, C), or, more commonly, are embedded among the superficial cells of the thallus (fig. 4, D); they are sometimes confined to special branches. The tetrasporangia usually occur on individuals devoid of sexual organs, although in other respects similar to the sexual plants. A regular alternation of the two has been established in a considerable number of cases (cf. above).

In the more advanced groups the fertilized carpogonium develops filamentous outgrowths (gonimoblasts, fig. 4, H) which fuse with one or more auxiliary cells distinguished by rich protoplasmic content. At the points of fusion there arise bunches of sporogenous threads forming the carpospores, which produce the individuals bearing tetraspores. Only the protoplasm of gonimoblast and auxiliary cell fuse, their nuclei remaining far apart, so that the process gives rather the impression of a parasitism of the gonimoblast on the auxiliary cell than of a second process of fertilization. In the CRYPTONEMIALES the two or three gonimoblasts are long threads fusing repeatedly with auxiliary cells which are here located at the ends of neighbouring branches (fig. 4, H). In the remaining groups (GIGARTINALES, RHODYMENIALES) the auxiliary cells are associated with the carpogonia to form so-called procarps, and the gonimoblasts are quite short. Thus, in *Callithamnion*, there are two auxiliary cells flanking a cell of the main axis (fig. 4, I, a and b) and one bears the four-celled branch which ends in the carpogonium; two masses of carpospores are formed. In *Polysiphonia* and many other cases the single auxiliary cell and the carpogonial branch become enclosed, already prior to fertilization, by a cuplike outgrowth from the adjacent cells (fig. 4, E). The enlarged envelope subsequently forms an investment around the single mass of carpospores, the whole structure being termed a cystocarp. In forms with a compact thallus the cystocarps are often embedded in the surface layers (fig. 4, F). *Corallina* and its allies produce all their reproductive organs in flask-shaped cavities (conceptacles).

Blue-green Algae.—VII. MYXOPHYCEAE (CYANOPHYCEAE) are a very distinct class distinguished by their simple cell-structure, the absence of all motile stages, and the lack of sexuality. They are probably an ancient group which has retained primitive characteristics, and enjoy a very wide distribution, especially in freshwater and terrestrial habitats. The prevalent colour is blue-green, but other tints (violet, red, etc.) are not uncommon. The pigments (chlorophyll, yellow carotin, blue phycocyanin, and a red one similar to the phycoerythrin of red algae) are simply lodged in the peripheral protoplasm, there being no definite chromatophore. The central protoplasm (central body) is colourless and perhaps constitutes a rudimentary nucleus, quite unlike that of other plants. Its structure has been repeatedly investigated, but has not yet found an interpretation that meets with common consent. The products of photosynthesis are sugars and glycogen, the latter causing the brown colouration of the cells after treat-

ment with iodine. The cells often contain numerous granules, some of which consist of protein (cyanophycin granules). The cell-wall is frequently not sharply defined.

The simpler members are colonial and grouped as CHROOCOCCALES, most of which are palmelloid with the cells embedded in abundant soft mucus (e.g., *Gloeocapsa*, fig. 1, E); they form jelly-like masses on damp walls, rocks, etc. A different type is seen in *Merismopedia* (fig. 4, J) whose plates of deep blue cells are common in freshwater plankton.

The remaining Myxophyceae are filamentous (HORMOGONEALES). *Oscillatoria*, forming vivid blue sheets at the bottom of ponds in autumn, has simple threads (fig. 4, K), which may glide slowly through the water or exhibit slow pendulumlike movements to which the genus owes its name. Many of its allies have their threads encased in a firm mucilage sheath (e.g., *Lyngbya*). In *Phormidium* huge numbers of threads are agglutinated by their soft sheaths to form leathery or papery sheets which often cover rocks, etc., over considerable stretches. In *Scytonema* (fig. 4, N) the filament breaks at certain points and the two pieces push out of the sheath sideways to form paired branches. This "false branching" is common in a number of Myxophyceae. The threads of *Scytonema* and its allies exhibit occasional larger cells (*heterocysts*), which have a firm cellulose wall and whose contents are at first yellow, but ultimately disappear completely.

Heterocysts are also found in the unbranched filaments of *Nostoc* (fig. 4, L) and *Anabaena* (fig. 4, M). The coiled threads of the former are embedded in large numbers in soft mucilage to form spheres or leafy expanses on damp ground or in water. In *Rivularia* and its allies the heterocysts are always situated at one end of the filament, whilst the opposite one tapers to a point or ends in a long hair. *Stigonema* (fig. 4, O) is a more robust form with several rows of cells within the sheath and showing true branching.

In a very few cases the contents of heterocysts have been found to produce a new thread, but for the most part they do not fulfil any recognizable function. Reproduction in the Myxophyceae is usually accomplished vegetatively, by fission in the colonial forms and by the detachment of short lengths of thread called hormogones in the filamentous types. The hormogones perform slow, gliding movements, whose mechanism is not fully understood. Many Hormogoneales produce resting spores, enlarged thick-walled cells with abundant granules, which may arise from any cell of a thread, though commonly located near a heterocyst (fig. 4, M).

The Myxophyceae, though so simply constructed, are successful in many habitats (e.g., hot springs, the frozen Antarctic lakes) where few other algae (except diatoms) can exist.

PHYLOGENY

There can be little doubt that algae originated in the water and that they preceded in their evolution the more elaborate land-plants. The different classes, as well as some prevalently flagellate groups dealt with elsewhere (see PROTOPHYTES), are distinguished by special pigments in the chromatophores and by the products of photosynthesis. Each class thus has its distinctive metabolism and probably represents the outcome of a separate attempt at the creation of a holophytic organism. There is little evidence of any real relationship between the diverse classes, and a common ancestry is in the light of our present knowledge improbable. In several classes the ciliated individuals and the motile reproductive cells are of a distinctive and rather uniform stamp, and this fact has led to the practically universal adoption of the view that these algal classes originated from motile unicellular organisms (Flagellates) that gradually lost their power of movement and gave rise to filaments, etc., in the way that has been above indicated. In red and blue-green algae, where no motile stages exist, a like origin from unicellular forms is assumed, though these need not necessarily have ever had the capacity of movement.

One may therefore picture the evolution of algae as having followed a number of separate lines, starting each with its unicellular ancestry and branching out in numerous special directions to develop as colonies, as palmelloid types, as filamentous forms

with diverse elaborations, etc. It is unlikely that these principal categories have ever originated directly from one another. They would rather appear to represent as many different attempts at the building of a body from the unicellular ancestry. It is significant that the same types of plant-body are repeated in different classes, since this indicates a parallelism in the evolution of the latter which has only recently been recognized. In some classes (e.g., Heterokontae) evolution has not progressed far, while in others (e.g., Phaeophyceae and Rhodophyceae where the simpler forms seem to be extinct) it has led to the production of highly specialized types in part of large size.

The biggest range in structure and reproduction is encountered in the green algae, although they have not attained to the complexity or dimensions of the brown and red seaweeds. The absence of the more specialized forms in this very vigorous and adaptable class is possibly due to their having migrated to the land in the remote past, although others hold that the higher plants originated from a hypothetical group of large green seaweeds now altogether extinct, and at least as complex as the brown and red forms of the present day.

OCCURRENCE AND DISTRIBUTION

Benthos.—Most algae grow permanently submerged, and are either attached (benthos) or free-floating (plankton). In freshwaters the algae of the benthos grow on stones, twigs, and larger aquatics, while the benthic seaweeds are nearly all lithophytes (i.e., fixed to rocks). Few algae (*Chara*, *Caulerpa*) can obtain a foothold in loose sand or mud, and a rock on a sandy beach often stands covered with vegetation like an oasis in a desert. Members of the benthos may become detached from their substratum and float freely, like the tangles of filamentous algae found in ponds, or the seaweed *Sargassum*, innumerable plants of which drift into the North Atlantic from the Gulf of Mexico and the Caribbean sea and thus give rise to the Sargasso sea. Unattached species of *Fucus* are not uncommon in salt marshes, but most seaweeds are doomed when torn away from their substratum. In rivers too all algal growth, other than the plankton, is attached, either encrusting rocks and pebbles (Myxophyceae, the red *Hildenbrandtia*) or forming long tresses trailing out with the current (*Cladophora*, *Ulothrix*, various red algae). All benthic forms bear numerous epiphytes and their dense tangles usually harbour a wealth of smaller algae and animal life.

Zonation.—The benthos usually exhibits more or less pronounced zoning. In lakes and pools this is due to the gradual diminution in light-intensity with increasing depth of water. The epiphytes on the submerged Phanerogams often show such zoning clearly, while in deeper water the growth consists in the main of Charales, *Nitella* usually thriving at greater depths than *Chara*. Further out, where the light is reduced to a minimum, the bottom bears only diatoms and sometimes cladophoraceous forms. Zonation is much more marked on rocky shores, where the littoral zone (i.e., the region between tide-levels) is of considerable extent. The highest levels are occupied by forms like *Pelvetia*, *Bangia*, *Prasiola*, etc., which are only under water for a few hours or indeed may grow at such a height, as to be merely wetted by spray and submerged only at spring tides. This spray-zone has its equivalent at the margins of large lakes, where the stones bear a growth of *Spirogyra adnata*, Myxophyceae, etc. Below the spray-zone, on northern shores, there follows a broad girdle of *Fucus*, various species of which occupy different levels; in the lower stretches they are mingled with *Ascophyllum*, while near low tide level *Himanthalia*, and Corallinaceae are often conspicuous features. In the sublittoral zone Laminariales are the dominant forms in all the colder seas. In the Mediterranean the littoral zone is specially characterized by *Corallina mediterranea*. Between tide levels are also found many green (*Ulva*, *Cladophora*) and red algae, but the latter, both as species and individuals, are most abundant in deeper water, where they are never exposed.

The various pigments (brown, red, blue, etc.) that accompany the chlorophyll probably serve in the first place to screen the latter against the intense illumination to which seaweeds are exposed when uncovered by the tide. The Rhodophyceae of the

littoral zone usually possess a dark red, almost black colour, and the brighter tints are met with only in the permanently submerged forms. Red seaweeds are, in fact, so sensitive to strong light that in aquaria they have to be grown behind dark glass.

The accessory pigments in the chromatophores, however, also effect an alteration in the region of maximum absorption of light. While in green plants this is in the red part of the spectrum, in the case of red algae it is in the green. So that at considerable depths, where the red and yellow rays have been absorbed, while the green and blue ones are relatively undiminished, red algae can still carry on photosynthesis and will be more successful than green or brown forms. It has been thought that their characteristic colour may have been acquired as a direct response to the quality of the light, but this is a debated point. It is well known, however, that some *Oscillatorias* will take on a colour complementary to that of the light to which they are exposed. Various Myxophyceae that grow in deep water, moreover, assume a red colour. It appears, however, from recent research that other factors than the colour of the light (e.g., lack of nitrogen) may bring about a change of pigmentation.

Phytoplankton.—The members of the phytoplankton are largely unicellular or colonial and are often highly adapted to a floating life. Many take the shape of flat plates (e.g., *Pediastrum*, *Merismopedia*, fig. 4, J), others bear numerous bristles (*Micractinium*, fig. 2, B) which heighten their buoyancy, while some (e.g., the many Myxophyceae responsible for "water-blooms") possess structures in their cells (pseudovacuoles) which render them lighter than water. A number of plankton algae (e.g., Volvocales), moreover, are freely motile and can thus maintain themselves in the surface layers where alone they obtain adequate illumination.

Marine phytoplankton consists largely of Diatoms, Peridiniae, and a few Heterokontae (*Halosphaera*, *Merinosphaera*), although a red filamentous member of Myxophyceae (*Trichodesmium*) is sometimes abundant in the warmer seas, hence the name of the Red sea. Freshwater phytoplankton is more diverse, including apart from Diatoms and Peridiniae, many Isokontae and blue-green algae. Since the phytoplankton constitutes the diet of many smaller animals, its abundance is often intimately related to the productivity in fish of oceanic or lacustrine waters. It varies considerably, both in quantity and quality, in different seasons of the year, and there is usually a more or less marked annual succession of forms (Diatoms, Peridiniae, etc.), many of which appear in swarms of rather limited duration.

Periodicity.—Such periodicity is also observable in the benthos and may be very striking in ponds, where four or more distinct phases can sometimes be distinguished during the year and certain forms (*Spirogyra*, *Tribonema*, etc.) are commonly only present during a limited period. The flora is usually poorest in the height of summer. Seaweeds likewise exhibit a periodicity, some being annuals and absent in the unfavourable season (winter or summer, as the case may be), whilst others though lasting for two or more years periodically shed parts of the thallus (cf. *Laminaria* and *Desmarestia* above). Reproduction is, moreover, commonly confined to definite periods; thus, many species of *Spirogyra* and *Oedogonium* are found fruiting mainly in spring, *Coleochaete* in the summer, the Laminariales produce their sporangia especially during the winter months, etc. Sexual reproduction in freshwater algae usually occurs during periods of bright sunshine.

Conditions of Existence.—The effect of light on the distribution of algae has already been considered. Second in importance is temperature, which probably in large part conditions the broad differences in the composition of the algal flora over the surface of the earth. In the colder seas other seaweeds are overshadowed by the large brown forms (Laminariales, Fucales), which are far less abundant in tropical and subtropical waters where red algae and Siphonales come to the front. Such regional differences are not so marked in freshwaters, although certain forms (*Cladophora*), common in temperate zones, are rare in the tropics, where moreover Myxophyceae play a bigger rôle than in colder latitudes. Some of these differences are no doubt determined by the higher oxygen-content of colder waters.

In extreme temperatures the algal flora acquires a very distinctive stamp. Thus, in hot springs the vegetation consists almost entirely of Myxophyceae and Diatoms, some of which are able to thrive at very high temperatures (80°C and more). Many algae, on the other hand, can withstand low temperatures and may be melted out from ice in a perfectly healthy condition. The frigid Antarctic lakes contain huge sheets of the blue-green *Phormidium* bearing a host of epiphytes. A peculiar flora consisting mainly of green algae occupies the surface of the perpetual snow-fields of the Alps, Andes, etc., and of the polar regions. Over wide areas the snow may exhibit a red colour due in the main to the resting-cells of *Chlamydomonas nivalis*, with which other forms are associated. Yellow snow, with a different flora, occurs in the Antarctic and is also known from the Alps.

Few algae can stand appreciable variations in the concentration of the water. Freshwater forms are not very tolerant of an excess of salts and seaweeds cannot thrive in dilute water, so that in estuaries and on salt-marshes only a limited number of algae are to be found.

Endophytes and Parasites.—The majority of epiphytic algae are attached merely to the surface of their substratum, but especially among marine forms some of the threads not uncommonly penetrate the latter, either invading only the external membranes of their host or burrowing deeper, so that they become active parasites. In most cases such forms afford little outward indication of their parasitism, but in the red alga *Harveyella* (*Choreocolax*) *mirabilis* the cushionlike thalli are devoid of all colour. It is rare for algae to be parasitic on higher plants, but *Cephaleuros*, one of the Chaetophorales, attacks the leaves of various tropical Phanerogams (including tea and coffee), causing more or less serious diseases.

A number of algae (*endophytes*) live almost entirely within the interior of other plants, without as a general rule being more than space-parasites. Such are the species of *Chlorochytrium* which occur in the fronds of the duckweed, etc., the *Nostoc* found in the liverwort *Anthoceros*, and the species of *Anabaena* that inhabit *Azolla* and the roots of various higher plants. In other cases the endophyte merely lies within the thick surface membranes of its host (many marine algae). A more intimate relation (*symbiosis*) exists in the case of the "green cells" (*Chlorella* spp.) found within the bodies of various lower animals, and the association of *Trebouxia*, *Trentepohlia*, and certain Myxophyceae with fungi to form lichens. Here the alga receives both protection and food from its partner (animal or fungus), which in turn profits by absorbing some of the products of photosynthesis of the alga.

Terrestrial Algae.—Numerous algae can exist more or less successfully out of water. The amphibious seaweeds of the littoral zone form a case in point. Somewhat similarly situated are the forms (*Botrydium*, *Vaucheria*) that grow on the damp mud round the edges of pools and ditches and which form resting spores as soon as the mud dries. There are, however, many algae living in and on soil, which are more highly adapted to withstand prolonged drying. The subterranean community comprises green (*Chlorococcum*) and blue-green forms, as well as diatoms, cultivated soils in general having a richer flora than natural ones. There can be no doubt that these algae fulfil an important rôle in the soil. A capacity to fix atmospheric nitrogen has been attributed to them, but no decisive proof is yet forthcoming. The gelatinous sheaths of many soil-algae, especially Myxophyceae, may well serve as a home and as a source of carbohydrate-supply for nitrogen-fixing bacteria, and herein may lie their chief importance.

The numerous subaerial algae are mainly green and blue-green, the latter playing a dominant part in the warmer humid regions of the world, where they constitute important primary colonizers of rock-surfaces and may often cover the latter for many hundreds of square yards with sheets of distinctive tint, giving a characteristic coloration to the landscape. In temperate regions green terrestrial algae are more conspicuous. Every one will be familiar with the green covering on tree-trunks, etc., due to *Pleurococcus* and other unicellular forms, which possess such a capacity to resist desiccation that they will survive months of extreme

drying in a desiccator over concentrated sulphuric acid without harm. Other examples of green subaerial algae are *Zygonium ericetorum*, one of the Conjugatae whose purple or greenish wefts cover extensive tracts of peaty soil, *Hormidium* found on clayey soils, and *Trentepohlia* whose orange tufts are particularly common in hilly districts and in the damp tropics. All these can survive long periods of drought without any appreciable change, resuming growth as soon as wet weather sets in.

Geographical Distribution.—While the broad differences in the character of the algal flora in diverse situations and in different regions of the earth are without difficulty related to special factors, the analysis of the conditions that determine local variations is still in its infancy. Such variations are patent to any one who makes a study of the algae of a limited region. Thus the algal flora of a moorland pool differs from that of one situated in meadow land, that of a lake differs according as the bottom is rocky or covered with silt, calcareous waters are poor in algal growth, etc. Similarly the vegetation of the sea-shore varies with the nature of the rocks, the extent of wave-action, the presence of currents, and the amount of detritus borne by the waves. Other differences appear to depend rather on geographical than on ecological factors. Thus, the desmid flora has a distinctive character in different parts of the world, and desmids appear to be entirely absent from the Antarctic continent, though abundant in the Arctic. Similar observations may be made with reference to the geographical distribution of seaweeds.

Uses.—Relatively few algae are of economic importance. Seaweeds are in many places employed as a convenient form of manure. A species of *Porphyra* (*P. laciniata*) and the red seaweed *Rhodomenia palmata* are used as food in some places, the latter being known as dulse. Agar-agar, a substitute for gelatine, is derived from a species of *Gracilaria*, while another red seaweed, carrageen (*Chondrus crispus*), has been used as an invalid food. Iodine was at one time mainly obtained from the ash of seaweeds.

Fossil Algae.—The dense incrustation of carbonate of lime found in various Siphonales and in the Corallinaceae has already been mentioned, and very similar forms are known as fossils in the Trias as well as in the Palaeozoic from the Silurian onwards. Such algae have evidently contributed to no small extent to the building of limestones, just as the *Lithothamnions*, etc. (Nullipores) are important agents in the formation of coral-reefs at the present day. Algae, which are not thus encrusted, are not so readily preserved as fossils, and of such we have little more than a fairly reliable record of their presence in earliest times; some of the forms in question are of large dimensions (e.g., the Devonian *Nematophycus*) and may have been similar to Laminariales. For fossil diatoms, see BACILLARIALES.

BIBLIOGRAPHY.—The following three works contain an up-to-date account of the various classes of algae and afford a complete bibliography up to the time of their publication: F. Oltmanns, *Morphologie und Biologie der Algen* (Jena, 1922); G. S. West and F. E. Fritsch, *British Freshwater Algae* (1927); G. S. West, *Algae*, Cambridge Botanical Handbooks, Vol. I. (1916). A more popular account is G. Murray, *An Introduction to the Study of Seaweeds* (1895). Of general systematic works the most important are: J. B. de Toni, *Sylloge Algarum*, vol. i. *Chlorophyceae*, vol. ii. *Bacillariaceae*, vol. iii. *Fucoideae*, vol. iv. *Florideae*, vol. v. *Myxophyceae* (by A. Forti) (Padua, 1889-1907); Engler and Prantl, *Natürliche Pflanzenfamilien*, *Chlorophyceae* (vol. 3, 1927, by H. Printz); *Phaeophyceae* (I. Teil, Abt. 2, by F. R. Kjellman and supplement by N. Svedelius, 1897 and 1909); *Rhodophyceae* (I. Teil, Abt. 2, by Fr. Schmitz and N. Svedelius, 1897 and 1911); *Schizophyceae* (I. Teil, Abt. 1 by O. Kirchner, 1900); A. Pascher, *Süßwasserflora Deutschlands, Oesterreichs, und der Schweiz* (Jena, 1912-27)—the last copiously illustrated and semi-popular. For seaweeds, see also W. H. Harvey, *Phycologia Britannica* (1846-55); *Nereis Boreali-Americana* (1851-58); *Phycologia Australica* (1858-63); E. Wuitner, "Les Algues marines des côtes de France," *Encyclopédie pratique du naturaliste*, VII. (1921); and L. Newton, *Handbook of British Seaweeds* (pubd. by British Museum, 1928). Many other less comprehensive systematic works, as well as the many monographs dealing with separate groups, will be found cited in one or other of the above. The biological aspects are more particularly treated in H. B. Ward and G. C. Whipple, *Freshwater Biology* (1918). (F. E. F.)

ALGARDI, ALESSANDRO (1602-1654), Italian sculptor, was born at Bologna in 1602, and attended the school of the Caracci. The turning point in Algardi's fortune was the accession

of Innocent X., of the Bolognese house of Panfili, to the papal throne in 1644. He was employed by Camillo Panfili, nephew of the pontiff, to design the Villa Doria Panfili outside the San Pancrazio gate. The most important of Algardi's other works were the monument of Leo XI., a bronze statue of Innocent X. for the capitol, and, above all, *La Fuga d'Attila* an alto-relievo in which the two principal figures are about 10ft. high. In 1650 Algardi met Velasquez, who obtained some orders for his Italian companion in Spain. Thus there are four chimneys by Algardi in the palace of Aranjuez, where also the figures on the fountain of Neptune were executed by him. The Augustine monastery at Salamanca contains the tomb of the count and countess de Monterey, which was also the work of Algardi. He was most successful in his portrait-statues and groups of children, where he was obliged to follow nature most closely. He died in Rome on June 10, 1654.

See *Le arti di Bologna disegnate da A. Caracci ed intagliate da S. Giulini, con assistenza d'Alessandro A. Algardi* (1740).

ALGAROTH, POWDER OF, a basic chloride of antimony. It was known to Basil Valentine, and was used medicinally by the Veronese physician Victor Algorotus about the end of the 16th century. It may be prepared by the addition of much water to a solution of antimony chloride, a bulky amorphous precipitate being formed, which, on standing, gradually becomes crystalline. It is soluble in hydrochloric acid and tartaric acid, but insoluble in alcohol; its possible composition is represented by $\text{Sb}_4\text{O}_5\text{Cl}_2$.

ALGAROTTI, FRANCESCO, COUNT (1712-1764), Italian philosopher and writer on art, was born on Dec. 11, 1712, at Venice and died at Pisa on May 3, 1764. He studied at Rome and Bologna, and at the age of 20 went to Paris, where he enjoyed the friendship of Voltaire and produced his *Neutonianismo per le dame*, a work on optics. Voltaire called him his *cher cygne de Padoue*. Frederick the Great made him a count of Prussia (1740) and court chamberlain (1747). Augustus III. of Poland honoured him with the title of councillor. In 1754, after seven years' residence partly in Berlin and partly in Dresden, he returned to Italy, living at Venice and then at Pisa. He was a man of wide knowledge, a connoisseur in art and music, and the friend of most of the leading authors of his time. His chief work on art is the *Saggi sopra le belle arti* ("Essays on the Fine Arts").

The best complete edition with biography was published by D. Michelessi (1791-94).

ALGARVE or the **ALGARVES**, ancient kingdom and province in the extreme south of Portugal, corresponding with the modern administrative district of Faro, and bounded on the north by Alentejo, east by the Spanish province of Huelva, and south and west by the Atlantic ocean. Population (1920) 268,294; area 1,937 square miles. The province is about 85 m. from east to west; 22 m. from north to south. The Serra de Malhão and the Serra de Monchique extend in the form of a crescent across the northern part of the province, and sweep round to the lofty promontory of Cape St. Vincent, the south-west extremity of Europe. This headland is famous as the scene of many sea-fights, notably the defeat of the Spanish fleet by the British in Feb. 1797. The coast is fringed for 30 m. from Quarteira to Tavira, with long sandy islands, through which there are six passages, the most important being the Barra Nova, between Faro and Olhão. The navigable estuary of the Guadiana divides Algarve from Huelva, and its tributaries water the western districts. From the Serra de Malhão flow the Silves and Odelouca, which unite and enter the Atlantic below the ancient town of Silves. The level country along the southern coast produces grapes, figs, oranges, lemons, olives, almonds, aloes, and even plantains and dates. The principal exports are dried fruit, wine, salt, tunny, sardines and anchovies. The only railway is the Lisbon-Faro main line, which passes north-eastward from Faro, between the Monchique and Malhão ranges. The name of Algarve is derived from the Arabic, and signifies a land lying to the west. The title "king of Algarve," held by the kings of Portugal, was first assumed by Alphonso III., who captured Algarve from the Moors in 1253.

ALGÄU or **ALLGÄU**, a small district in south-west Bavaria, belonging to the province of Suabia and Neuburg. The

name formerly applied to a much larger territory, extending to the Danube on the north, the Inn on the south and the Lech on the west. The Algäu Alps contain several lofty peaks, e.g., Mädelegabel (8,681 ft.). The district is celebrated for cattle, milk, butter and cheese.

ALGEBRA, according to present English usage that branch of mathematics which considers primarily the representation of numbers by means of letters. Speaking more precisely, that part of mathematics which considers the relations and properties of numbers by the aid of general symbols, usually letters ($a, b, c, \dots x, y, z$) and signs of operation ($+, -, \times, \dots$) and relation ($=, >, <, \dots$). For example, the statement that the area of a rectangle is equal to the product of the number of units of length in the base multiplied by the number of units in the height, is algebraically expressed by the symbols $A = bh$, where A stands for the number of square units of area; b , for the number of linear units in the base; and h , for the number of linear units in the height. Similarly, the expression $x^2 + 5x = 14$ states that there is a number (represented by x) such that its square, plus five times itself, is equal to 14. Algebraic symbolism and operations enter into nearly all branches of science, including the various subdivisions of mathematics. In certain cases, however, as in vector analysis ($q.v.$), the letters are not restricted to the representation of numbers. In its broader sense algebra treats of equations, polynomials, continued fractions, series, number sequences, forms, determinants, and new types of numbers. These topics will be found discussed in separate articles. It considers the fundamental theorem that every integral equation $f(x)$ with real coefficients has at least one real or complex root (*see* EQUATIONS), indeterminate equations (*see* DIOPHANTINE EQUATIONS), general algebraic equations of the third and fourth degrees, numerical higher equations (*see* EQUATIONS), and it enters into such important branches as the calculus, trigonometry and the theory of functions ($q.v.$). As a preparation for all this work, however, there is the elementary part of the subject. It is the purpose of this present article to discuss a number of topics which will show to the general reader the nature of algebra in its initial stage, and to show the teacher why algebra is taught in the schools. This discussion will be supplemented by references to treatises which will enable the student to find the underlying philosophical principles of the science.

Changes in Scope.—If by the word *algebra* we mean that branch of mathematics by which we learn how to solve the equation $x^2 + 5x = 14$, written in this way, the science begins in the 17th century. If we allow the equation to be written with other and less convenient symbols, it may be considered as beginning at least as early as the 3rd century. If we permit it to be stated in words and solved, for simple cases of positive roots, by the aid of geometric figures, the science was known to Euclid and others of the Alexandrian school as early as 300 B.C. If we permit of more or less scientific guessing in achieving a solution, algebra may be said to have been known nearly 2000 years B.C., and it had probably attracted the attention of the intellectual class much earlier. The scope of all early algebra was limited to a study of equations or to the solution of problems which at present would be solved by their aid. In the 16th century, after the advent of the printed book in Europe, the field was enlarged through the efforts of men like Christoff Rudolff (*Die Coss*, 1525; 2nd ed. by Michael Stifel, Königsberg, 1553, 1554), Robert Recorde (*Whetstone of witte*, London, 1557), Rafael Bombelli (*L'Algebra parte maggiore dell'arimetica*, Bologna, 1572) and Christopher Clavius (*Algebra*, Rome, 1608), becoming more of a generalized arithmetic, the fundamental operations with numbers being duplicated with rather crude algebraic symbols. The perfecting of symbolism in the 17th century greatly extended the domain of algebra and rendered possible the development of the higher branches of the subject.

Changes in Name.—The name "algebra" is quite fortuitous. When Mohammed ibn Mûsâ al-Khowârizmî (Mohammed, son of Moses, the Khowarezmite), a native of Khowarezm (Khwarezm), wrote in Baghdad (c. 825), he gave to one of his works the name *Al-jabr w'al-muqâbalah*. The title is sometimes translated as "restoration and equation," but the meaning was not clear even to the later Arab writers. Of late it has been thought that al-jabr is

Arabic, while muqâbala is from the Persian, and that each meant or referred to an equation. At any rate, al-Khowârizmî's work was the first to bear the title "algebra," and the treatise was so important as to cause the name to be adopted, often with strange variations in spelling, by later writers. Various other names have been given to the science, such as *arithmetica* (see ARITHMETIC), *Bija Ganita* (Brahmagupta's Hindu treatise, c. 628, the term meaning calculation with primitive elements), *T'ien-yuen* (Chinese, "celestial element"), *Kigen seihô* (one of the Japanese names, referring to "revealing unknowns"), *Fakhri* (al-Karkhi, c. 1020, who gave this name to his algebra in honour of his patron, Fakhr al-Mulk), *Regola de la cosa* (Rule of the *cosa*, Lat. *causa*, Fr. *chose*, the unknown quantity), *Ars magna* ("great art," used by Cardan in 1545), the German *Die Coss* and English *Cossike arte* (both in the 16th century). Most of these names referred to the science of the equation, and this is the meaning assigned to elementary algebra in certain European languages at present, the fundamental operations with literal expressions being then included under the term "arithmetic."

Summary of the Changes in Meaning.—We may, therefore, summarize the leading steps in the growth of algebra as follows: (1) The period of the puzzle problem relating to numbers, with little or no symbolism, c. 1800 B.C. to A.D. 275; (2) The inclusion of the geometric problem of completing the square, thus leading to the finding of a line that would be represented by x in a modern quadratic equation; (3) The development of a systematic although a crude symbolism, applied to the theory of numbers, as in the *Arithmetica* of Diophantus (c. 275), this theory including certain indeterminate equations; (4) A more critical study of equations with some approach to scientific treatment, as in the period of Muslim ascendancy, c. 800–c. 1200; (5) The rise of the theory of equations, beginning with the solution of the cubic and the biquadratic in the 16th century (see CARDAN; TARTAGLIA); (6) The development of a convenient symbolism, chiefly in the century 1550–1650, changing algebra from a crude theory of equations to an analytic subject concerned with algebraic numbers and polynomials; and (7) The modern development of higher algebra.

ARTIFICIAL NUMBERS

The numbers used in counting objects have long been known as *natural numbers*. Numbers that are not naturally used in counting objects are commonly called *artificial numbers*, a term that is open to certain objections. From various points of view the number $\frac{3}{2}$ is as natural as 2, and $\sqrt{5}$ as naturally comes into use as 5, although we cannot look at an object $\frac{3}{2}$ of a time nor can we pick up a book $\sqrt{5}$ times. The term is convenient, however, even though it may be as inappropriate as "imaginary" in connection with $\sqrt{-3}$, or "fraction" (in its primitive sense) in connection with $\frac{2}{2}$, $\frac{5}{2}$, $\frac{1}{2}$, $\frac{3}{4}$. The preceding discussion

leads to a much larger and more important question as to the meaning of number itself. (See NUMBER; NUMBERS, THEORY OF; COMPLEX NUMBERS.)

Algebraic Scale.—If we construct a scale of integers,

1, 2, 3, 4, ..., and count backwards (to the left) by repeatedly subtracting 1, we have ... 4, 3, 2, 1, 0. The next count on the scale carries us beyond the point marked 0 on the scale, to 1, 2, 3, 4, ... in the opposite direction, just as we count 1, 2, 3, 4, ... below zero on a thermometer. For obvious reasons we find it convenient to speak of these symbols on the other side of zero as representing numbers, even though we cannot look at an object "three-less-than-zero" or "three-on-the-other-side-of-zero" times. We were led to these particular artificial numbers by subtracting as we went down the scale, and so we come to designate them a minus sign, thus giving to this sign the qualitative meaning (say "negativeness") instead of the operative one (subtraction). Such numbers are imaginary in some senses and natural in others. If

we wish to emphasize the positive nature of 1, 2, ..., we may write them as +1, +2, ..., although even without any sign they are considered positive.

Further, on the algebraic scale we can represent such fractions as $\frac{1}{2}$ and $-\frac{3}{4}$, and such surd numbers as $-\sqrt{2}$ and $\sqrt[3]{5}$, so these

are as real in certain situations as the integers themselves.

If the expression a/b , in which a and b are natural numbers, does not denote a natural number, it is called a *fraction*, but since division by 0 has no meaning, the case in which $b=0$ is excluded. Integers and fractions are classified as *rational numbers*. More generally speaking, a rational algebraic fraction is the quotient of any integral function by any other integral function. Certain numbers such as $\sqrt{2}$ and $\sqrt[3]{7}$ do not come within the definition of rational numbers, and are called *irrational numbers*. In elementary algebra we also meet with certain numbers represented by the symbol $a\sqrt{-1}$, and these are called *imaginary numbers*. Numbers like $a+b\sqrt{-1}$, are called *complex numbers*. (See NUMBER; COMPLEX NUMBERS; FRACTIONS; NUMBERS, THEORY OF.)

Algebraic Expressions.—An expression consisting of a single letter, or made up either of letters or of letters and numerals, combined so as to represent some or all of the operations of addition, subtraction, multiplication, division, involution (the finding of powers) and evolution (the finding of roots), is an *algebraic expression*. If it does not involve addition or subtraction, it is a monomial; but in the expression $a-(b+c)$, $-(b+c)$ is considered as a monomial, and so in other similar cases involving signs of aggregation (parentheses, brackets, etc.). If an algebraic expression is not a monomial, it is a *polynomial*, the binomial (two-term) and trinomial (three-term) being special types. In algebra, the letters of an expression represent numbers of some kind. In the monomial ab , a and b are *factors* of the expression. If the value of either factor, say a , is known and is to remain the same throughout the discussion of the expression, it is called a *constant*; but if it may have any value we please to give it and change from one value to another, it is called a *variable*. Constants are often represented by the first letters of the alphabet (a, b, c, \dots), and variables by the last letters (x, y, z), but this is not a universal rule especially in physical formulas. In an equation, say $2a-x=4$, x usually represents a number to be found—"the unknown quantity"—the first letters of the alphabet representing numbers supposed to be known. In the monomial $2ax^2$, we may speak of any factor as the *coefficient* of the rest of the expression, but it is customary to speak of 2 as a numerical coefficient, and of $2a$ as the coefficient of x^2 , the coefficient being the first factor or factors. For example, in the expression $\frac{1}{2}(a+b)x^2y^3$, $\frac{1}{2}$ is the coefficient of $(a+b)x^2y^3$, and $\frac{1}{2}(a+b)$ is the coefficient of x^2y^3 , and it is also allowable to speak of $\frac{1}{2}(a+b)x^2$ as the coefficient of y^3 , and so on. In the expression x^3 , 3 is the *exponent* of x , and similarly in the case of x^m . In the expression mx , the coefficient m (if it be an integer) represents the number of times that x is taken as an addend; while in the expression x^m , m (if it be an integer) represents the number of times that x is taken as a factor. In each case the meaning is later extended to permit of m being any kind of number (fractional, surd, imaginary, etc.).

Function.—An expression like $2x+5$ is called a *function* of x and is said to "depend upon" x for its value. Similarly, $2x+y^3$ is a function of x and of y . For brevity we may, in any discussion, write $f(x)$ for the function of x , and $f(x, y)$ for the function of x and y , and so on for other variables. We may then, in discussing $x-3$, for example, say that $f(1)=1-3=-2$, $f(7)=7-3=4$, $f(-2)=-2-3=-5$, $f(0)=0-3=-3$, and so on, according to the value of x which we substitute in $x-3$.

The Elementary Operations.—From the standpoint of actual use, whether in the natural sciences or in pure mathematics, there is little need for the ordinary operations involving polynomials, therefore a brief treatment of the four fundamental operations, limited chiefly to binomial operators, with a slight reference to the theory of roots, is all that is essential to the further study

of the science of algebra. The operations upon algebraic fractions were adapted from arithmetic after the introduction of the improved symbolism of the 17th century. They later became more complicated owing to the doctrine of formal discipline, the result leading to an expenditure of time quite out of proportion to the use made of them. In the 19th century the time consumed in reducing artificial fractions to lowest terms, and in operations involving polynomials was excessive.

Ratio.—In practical work a ratio is considered simply as a fraction, although fundamentally the ratio of the circumference to the diameter of a circle is a transcendental number and not a fraction, as we define the term. Practical work in a laboratory or workshop is not concerned with irrationals as such; it seeks for precision within certain designated limits, recognizing that all measurement is approximate. On this account and because of the immaturity of the pupils, elementary algebra looks upon a proportion as a fractional equation, and deals with all ratios as simple fractions, ignoring the distinction between algebraic and arithmetical fractions, and the fact that the ratio may be irrational.

Uses of Irrational Numbers.—In the solution of quadratic equations, excepting those artificially constructed to give only integral values of the unknown quantity, the roots are generally irrational, not being expressible as the quotient of a/b , where a and b are integers. This is seen in the simple quadratic $x^2=2$, where $x=\pm\sqrt{2}$. Since early arithmetic was concerned largely with rational numbers, the irrational ones were generally assigned to algebra, the branch of mathematics in which they were needed. The purpose in placing them there was soon obscured, however, the result being a much more extensive treatment of the subject than was warranted by any practical considerations. If, in a physical problem, there is need for solving the equation $x^2=243$, it is important to find the value of x to a definite degree of approximation. If it is stated that $x=\pm\sqrt{243}$, nothing is gained by writing this result as $\pm9\sqrt{3}$. An expression like $\sqrt{2}$ and $\sqrt[3]{17}$, but (for no very good reason) not like $\sqrt{3+\sqrt{2}}$, is known as a *surd*, from a mediaeval Latin translation of an Arabic rendering of the Greek *ἀλογος* (*al'ogōs*, irrational). Until recently the finding of the square root of a binomial surd, as of $7-4\sqrt{3}$ or of $12+2\sqrt{35}$, was a familiar operation in elementary algebra, and there is still good cause for complaint that the work in surds is excessive. With the properties of such transcendental numbers as e and π , elementary algebra is little concerned. (See NUMBER.)

Factors.—The factorizing of polynomials has a place in the theory of equations and in the advanced study of polynomials, but its value in elementary algebra is slight. In the algebra that the pupil will use in the sciences or in the mechanical arts its legitimate place is not large. The needs of the pupil are usually met by the cases of monomial factors, and of the binomial factors of expressions of the type $x^2+(a+b)x+ab$ and x^2-y^2 .

The original idea, carried over from arithmetic, was that factors should be integral and rational. In practical use, however, it is often necessary to enlarge this conception, and to speak of $x-\frac{1}{a}$ as having the factors $x+\frac{1}{a}$ and $x-\frac{1}{a}$; of $x+\sqrt{a}$ and $x-2\sqrt{b}$ as factors of $x^2+x(\sqrt{a-2\sqrt{b}})-2\sqrt{ab}$; and of \sqrt{a} , \sqrt{b} , and \sqrt{c} , as factors of \sqrt{abc} .

The Equation.—Expressions of equality are of several types. For our present purposes it is necessary to consider only three: (1) $2+3=5$ or, after the operation has been performed, $5=5$; (2) $a+a=2a$; (3) $x+2=5$. The first is a numerical relation between known numbers, and does not represent an algebraic equation; the second represents a relationship that is true for all values of a , and hence is called an *identity*, another example being $(a+b)^2=a^2+2ab+b^2$; the third is an algebraic equation, true in this case for one and only one value of x , this value being known as the *root* of the equation. An identity is often indicated by the symbol \equiv instead of $=$. In the present discussion we consider only elementary algebraic equations with rational and integral terms. The general treatment with a consideration of the existence of a root is given in the article on EQUATIONS.

Linear Equations.—Considerations of analytic geometry (*q.v.*) have led to the use of the term *linear equation* to mean an equation of the first degree having any number of variables. The oldest part of elementary algebra, so far as known, relates to the solution of linear equations in one unknown, the type form reducing, through the final stage (in modern symbols) of $px=q$, to $x=k$. This type of equation is found in the Ahmes (Rhind) Papyrus (*c.* 1700–1600 B.C.) and is the one found most frequently for a period of more than 3,500 years, varying merely in the language and symbols employed. Such number puzzles have been used by substantially all writers on algebra, and in modern times they have found a wide range of practical applications in the sciences, in industry and in commerce.

Linear equations of the type $ax+by+c=0$ and $a'x+b'y+c'=0$ generally have common values for x and y ; that is, they are *simultaneous*. For example, the two equations $x+3y-1=0$ and $2x+9y+1=0$ have in common the roots $x=4$, $y=-1$. Each equation is, by itself, *indeterminate*, having an infinite number of roots. For example, the first of these equations, $x+3y-1=0$, is satisfied by $x=0$, $y=\frac{1}{3}$, and similarly by the pairs of values $(1, 0)$, $(2, -\frac{1}{3})$, $(3, -\frac{2}{3})$, $(4, -1)$, and so on; but there is only one pair which satisfies both of the equations. In modern textbooks this is made clearer by means of graphs, each equation being represented by a straight line, and these lines having, in general, one point in common. This introduction of the elements of analytic geometry into elementary algebra is helpful in understanding the meaning of roots. For example, the two equations $3x-7y=6$ and $2x-4\frac{2}{3}y=4$ are satisfied by any number of pairs of values, their graphs being coincident; while $3x-7y=6$ and $2x-4\frac{2}{3}y=5$ cannot be satisfied by any pair of values, their graphs being parallel. (See ANALYTIC GEOMETRY.)

Simultaneous linear equations are solved by several methods, the equations as given in the textbooks being artificially constructed so as to illustrate each. These methods are sufficiently discussed in such works. If, however, only a single method is to be given for solving a pair of simultaneous equations, this method being made mechanical by much practice, that of substitution is the most satisfactory in cases that actually arise in science or industry. This method consists in finding in either equation the value of one unknown in terms of the other, and then in substituting this value in the other equation. For advanced classes the method of determinants (*q.v.*) is interesting and valuable.

Simultaneous linear equations with more than two unknown quantities have an interest as puzzles and some value in developing skill in manipulating algebraic expressions, and they also have value in certain technical fields and in certain commercial problems. During the centuries there have been developed various devices for solving specially constructed types, but such devices and types lack generality and hence they have little value except as recreations. In actual practice with real problems the method of determinants is the best. The question of the possibility of solution of given sets should be considered, as in the case of simultaneous equations with two unknowns.

Quadratic Equations.—An equation of the type $ax^2+bx+c=0$ in which b and c may have any finite numerical values, and a may have any finite value except zero, is a *quadratic equation* (from the Latin *quadratus*, a square). Such equations are frequently needed in solving scientific problems. There are several methods of solving such an equation, including the following: (1) Reducing to the form $ax^2+bx+c=0$; resolving into factors $(px+q)(p'x+q')=0$; equating each factor to zero; and solving the two resulting linear equations; (2) Completing the square; (3) Using a general formula, usually developed by the second method. Of these, (1) is too difficult in a practical case like $1.47x^2-0.36x+14.02=0$, however easy it may be in an artificial one like $x^2-5x+6=0$; (2) is a traditional method, essentially due to the Alexandrian school (*c.* 300 B.C.); it requires the memorizing of a process—the completion of the square; and it is arithmetically difficult in practical cases; (3) requires the memorizing of a formula, but in problems that are practical it is usually the easiest of the three.

Simultaneous quadratic equations can be solved by elementary

algebra (the biquadratic not being there given) only in cases artificially constructed to admit of easy solution. The analytic explanations given in textbooks may profitably be supplemented by the use of the graph. This will serve to show the difference between a case like $2x-3y=5$, $x^2+3y^2=7$, and a case like $x^2+y=7$, $x+y^2=11$. In the former substitution reduces the problem to the solution of a quadratic; in the latter case, to the solution of an equation of the fourth degree. The nature of such equations may profitably be shown by the aid of graphs.

Ratio and Proportion.—As already stated, this subject is best treated in connection with fractional equations. Since in elementary algebra the letters represent numbers, and since it is necessary to assume at this stage that operations with irrational numbers are subject to the ordinary laws that obtain with integers, the subject offers no new features. The range of application to outdoor measurement and to simple physical problems is extensive. With this method of treatment such special names as *antecedent*, *consequent*, *means*, and *extremes* lose their importance in practical problems. Moreover, the old notation, $a:b::c:d$, may profitably give place to the more familiar and more easily understood symbols representing a fractional equation.

Variation.—The subject of variation, which formerly had a symbolism of its own, is more conveniently and clearly treated as a topic under ratio and proportion or, what is substantially the same, by the ordinary method of equations; that is, variation may be expressed by the aid of the equation $x=ky$ (direct variation) or by $xy=k$ (inverse variation).

TRIGONOMETRY, SERIES, APPLICATIONS

A movement is taking place among teachers of mathematics to encourage the consideration of the simple trigonometry of the right-angled triangle as a special chapter of algebra, following the topics of ratio and proportion. (See TRIGONOMETRY; LOGARITHMS.)

Elementary Series.—Amongst those inheritances from mediaeval arithmetic which found their way into the early textbooks in algebra, was the topic of progressions. This term usually covered the rules for the summation of simple types of arithmetical and geometric series, and sometimes a brief discussion of harmonic series. With the improved symbolism came the formulae relating to these sequences, and in recent years the special name *progression* has tended to give place to *series*. The subject, together with the related Binomial Theorem, is sufficiently treated in current textbooks. (See SERIES; NUMBER SEQUENCES; LIMIT; BINOMIAL FORMULA.) Elementary algebra contains many practical applications of equations, and modern textbooks are using these to supplement or replace the less valuable inheritances. It would be unfortunate if any attempt should be made to abolish all of this traditional material; it could never have held its place through the centuries if it had not possessed such an interest for young people as to insure the degree of permanence which we see. It has often been from the study of the interesting but impractical that the most practical mathematicians as well as the leaders in pure mathematics have been made. The most important application of elementary algebra is found in the formula. This is the part of algebra which the pupil will use most frequently in science, in mensuration, in technical work of all kinds, and in such parts of more advanced mathematics as series, determinants, trigonometry, analytic geometry, and the calculus. To the formula, therefore, it is desirable that increased attention should be given.

FUNDAMENTAL PRINCIPLES ASSUMED

There are certain axioms which are often set forth in textbooks, as the statement "If $ab=p$, then $a=p/b$," but others, equally important from the standpoint of logic are properly assumed tacitly. Such for example, are the statements that $a+b=b+a$, the commutative law of addition; that $ab=ba$, the commutative law of multiplication; that $a+(b+c)=(a+b)+c=a+(b+c)$, the associative law of addition; that $abc=(ab)c=a(bc)$, the associative law of multiplication; and that $a(b+c)=ab+ac$, the distributive law. Such axioms and laws seem so evidently true to the mind of the child that any exhaustive discussion of them in

the early years is profitless. They may or may not be universally true; in fact, some of them are not; but they are true in the immediate and limited field of the beginner's study.

Laws of Equations.—As stated above, the axiom "If $ab=p$, then $a=p/b$ " is often set forth in elementary textbooks, but it ceases to have any meaning for the pupil if $b=0$. Similarly the statement "If $a>b$, then $na>nb$ " ceases to be true if n is 0 or negative; and the statement "If $a=b$, then $\sqrt[n]{a}=\sqrt[n]{b}$ " also fails unless it is understood which of the n th roots in each case is to be taken, requiring a limitation upon the meaning of the symbol \sqrt . These laws are usually stated as axioms, with a statement of the limitations to be placed upon them in the elementary field. (See MATHEMATICS, FOUNDATIONS OF.)

Validity of Definitions.—Just as laws of operation which appear axiomatic to the beginner are seen to be wanting in universal validity as mathematics broadens, and as the laws of equations which are true in the early stages need close scrutiny when we leave the domain of the positive integers $+1, +2, \dots, +n$ (finite), so the definitions of the early years of instruction soon cease to have meaning, even before the pupil leaves the elementary stage. For example, ab does not mean that b is taken a times unless a is a positive integer; "minus a times" has no meaning unless and until the primitive use of "times" is changed, and similarly when a is equal to $\frac{2}{3}$, to $\sqrt{2}$, to $\log 7$ or to $\sqrt{-3}$; and a^n does not mean that a is taken n times as a factor when n ceases to be a positive integer. For this reason rigid definitions are not desirable.

Growth Imposes Consideration of Limitations.—The teacher of elementary algebra should early recognize that, as the science grows or as the pupil's knowledge increases, the early laws, axioms, definitions, postulates and significance of symbols constantly require further consideration of their limitations. For example, the statement that $a^m \div a^n = a^{m-n}$ must have the limitation imposed that m and n are positive integers and that $m>n$, unless negative and fractional exponents are admitted.

It is desirable that even the beginners in the study of algebra should see the necessity for maintaining the fundamental laws as the meaning of terms and symbols is broadened. For example, it would be unfortunate if a fractional or a negative exponent were to be so defined that $a^m a^n$ would cease to be equal to a^{m+n} , or that multiplication were to be given such a meaning that ab should not be equal to ba . As the pupil progresses in his study of mathematics he will meet with branches in which some of these laws cease to be valid, but his maturity will then permit of the necessary modifications.

HISTORY OF ALGEBRA

The earliest known treatise containing problems which would at present be called algebraic is the Ahmes Papyrus (also called, from the name of its former owner, the Rhind Papyrus) now in the British Museum, and written c. 1700-1600 B.C. The first of these problems reads as follows: "Ahe (or hau, transliterated by Egyptologists as 'h'w, meaning *heap, mass or quantity*), its whole, its seventh, it makes 19,"—that is, $x+\frac{1}{7}x=19$. The method of solving was by estimating the result and then correcting the error

FIG. 1.—HIEROGLYPHICS EXPRESSING THE EQUATION $x(\frac{2}{3}+\frac{1}{2}+\frac{1}{7}+1)=37$

by repeated trials. The Greek mathematicians were primarily geometers, and they made various kinds of geometric constructions by which they found a line segment corresponding to the root of an equation. Euclid (c. 300 B.C.), for example, solved problems equivalent to $xy=k^2$, $x\pm y=a$, and to $xy=k^2$, $x^2-y^2=a^2$. The only Greek to write extensively on algebra was Diophantus (c. 275). He was also the first writer to introduce any algebraic symbols of special significance, these including a character to represent the unknown quantity, a symbol for subtraction, the use of initial letters for equality, square and cube, and a scheme of combinations for other powers. In the Orient there is evidence of an early interest in problems which would now be solved by

algebra, and the Chinese were able to solve the quadratic equation before the Christian era. The Hindu works of Brahmagupta (c. 628), Mahāvīra (c. 850) and Bhāskara (c. 1150) contain a large number of problems solved by algebraic methods, and show considerable ability in analysis. In the Muslim world, and particularly at Baghdad in the time of the caliphs, two lines of mathematical thought converged, the first from Greek sources and the second from India. The result was the preparation of such textbooks as those of Mohammed ibn Mūsā al-Khawārizmī (c. 825), Abu Kamil (c. 900) and al-Karkhī (c. 1100). Of these, the algebra of al-Khawārizmī had the greatest influence upon European mathematics, being translated by Robert of Chester (c. 1140) and other mediaeval scholars. The Oriental writers mentioned were able to solve the quadratic equation, but whether their method originated in the East or was suggested by the Greeks is uncertain.

The beginning of printing in Europe found algebraists possessed of no convenient symbolism but, as already stated, able to solve the quadratic. Italy was the centre of learning and her scholars devoted much attention to solving the cubic equation. The latter solution was finally effected, with substantial completeness, by Tartaglia (q.v., 1535) being published by Cardan (q.v.) in his *Ars Magna* (1545). The biquadratic was solved by Ferrari (1540), a pupil of Cardan's, and was also published by the latter in the same work. The needed improvements in symbolism were generally made outside of Italy by such writers as Vieta (q.v., c. 1590), Harriot (q.v., c. 1600) and Descartes (q.v., 1637), with the notable extension of the exponential notation by John Wallis (q.v., 1655). The proof of the insolubility of the general equation of the fifth degree by algebraic methods is due to the investigations of Ruffini (1803, 1805), Abel (q.v., 1824) and Galois (q.v., 1831; posthumous publication, 1846). Elementary algebra may be said to have been substantially completed by the close of the 17th century, by which time higher algebra, especially through the

progress made in the study of equations, symmetric functions, and series, had already begun to rank as a special branch of mathematics.

HIGHER ALGEBRA

Much that is elementary in the sense of elemental, is not so in the sense of being adapted to the pre-university schools. Higher algebra of a sort is taught in these schools, and higher algebra of an entirely different sort is taught in the universities. In the pre-university schools the work serves as an introduction to the theory of equations, algebraic numbers, determinants, certain series, inequalities, limits and logarithms, and the simpler features of analytic trigonometry, analytic geometry and the differential calculus. In the universities it includes work in the theory of equations, the study of polynomials, combinatorial analysis, probability, matrices and various other fields. For the more important of these topics see AGGREGATES; ANALYSIS; ANALYTIC GEOMETRY; BARYCENTRIC CALCULUS; BINOMIAL FORMULA; TENSOR ANALYSIS; CALCULUS OF DIFFERENCES; COMBINATORIAL ANALYSIS; COMPLEX NUMBERS; DETERMINANT; EQUATIONS; DIFFERENTIAL FORMS. S.)

ALGEBRAIC FORMS. An algebraic form is a polynomial, all of whose terms are of the same degree in two or more variables. Thus $ax^2 + by + c$ is not a form, but $ax^2 + byz + cz^2$, of order two in three variables x, y, z is a quadratic ternary form. A form is also called a *quantic*, this general name resembling cubic, quartic or quintic. If its order is n , it is called an n -ic. Forms in two variables are called *binary*; in four variables, *quaternary*. Forms are interesting principally because they occur in equations for unknown quantities, and, since the time of Descartes (1637), in equations of geometric loci, such as curves, surfaces, families of lines or systems of circles. Their homogeneity is closely related to the modern development of projective geometry, in which the region known as "infinity" in the older geometry has no special treatment, but is like an extra axis or plane of co-ordinates, where the *ratio* of two co-ordinates becomes infinite or zero. Ratios take the place of measured distances. To equations in one unknown there will correspond binary forms; to those in two metric variables, ternary forms, and so on. Further, just as in geometry one considers often not single loci, but simply or doubly infinite systems of curves or surfaces, so algebraic forms may contain more than one set of variables; and the sets need not all occur to the same order, nor need two sets be composed of equal numbers of variables. A problem may arise, too, calling for the use of two, three or more forms at the same time; these are then termed a *simultaneous system*.

LINEAR TRANSFORMATIONS

For one set of variables it is often useful to substitute expressions containing a second, different set. An example of this is the change of axes, or planes, of reference in analytic geometry. Those expressions are most often linear (*i.e.*, of the order one) in the new system, and the change is called a *linear transformation*. For some reason, however, expressions of the second or higher order may be used; this case is less frequent and less simple, and can be treated as a linear transformation in an increased number of variables, plus the inclusion of an additional locus in the system under discussion. By any linear transformation, if the new variables are given the same names as the old, the old form is changed into a new one. Two forms so derivable one from the other are called *equivalent under the transformation*. By this definition, any form is equivalent to all that can be derived from it by linear transformations. Consider a binary quadric:—

$$f(x) = x_1^2 - x_2^2.$$

Let the transformations be

$$x_1 = 5y_1 + 6y_2,$$

$$x_2 = 3y_1 + 10y_2,$$

then

$$f(x) = (5y_1 + 6y_2)^2 - (3y_1 + 10y_2)^2, \\ = 16y_1^2 - 64y_2^2.$$

Call this new form $F(y)$, then

$$F(x) = 16x_1^2 - 64x_2^2,$$

and $F(x)$ is equivalent to $f(x)$. Such a transformation may be represented, between two binary forms, by means of indeterminate coefficients or parameters $\alpha_1, \alpha_2, \beta_1, \beta_2$, thus:—

$$\begin{aligned}x &= \alpha_1 y_1 + \beta_1 y_2, \\x_2 &= \alpha_2 y_1 + \beta_2 y_2,\end{aligned}$$

and it is reversible without ambiguity if the determinant $(\alpha_1\beta_2 - \alpha_2\beta_1)$ is not zero, for then these two equations can be solved for y_1 and y_2 .

Groups.—One reason for the employment of linear transformations is that all such form a group. (See GROUPS.) That is, if two linear transformations are made in succession, variables (x) into functions of (y), and the (y) into functions of variables (z), then the (x) are linear functions of the (z). The linearity is unchanged by compounding two or more linear transformations. One speaks often of equivalence under the *linear group*, meaning to exclude transformations whose determinant is zero; then the equivalence is a mutual relation. There are groups of linear transformations that do not include all such substitutions; just as there are in geometry rotations of a plane about one fixed centre, leaving a system of concentric circles unaltered. For some purposes, the group of linear substitutions whose determinant is 1 are applied; or the group of real transformations, excluding all that have any imaginary parameters. If imaginary substitutions are admitted, a quaternary quadric $x_1^2 + x_2^2 + x_3^2 - x_4^2$ is equivalent to another $x_1^2 + x_2^2 - x_3^2 - x_4^2$; not, however, if the group is that of *real* linear transformations. Two systems of forms in any number of sets of variables are equivalent under the group if the members of one system can be transformed into those of the other system by means of separate linear substitutions on all the different sets of variables involved. Two sets of variables that are subject to the same transformation are *cogredient*.

Equivalence of Quantics.—What happens to the coefficients of the various terms in a form, or quantic, when it is transformed into an equivalent quantic? It is seen, on trial, that the new coefficients contain the old in the first degree, but the parameters of the transformation to higher degrees, *each form to a degree equal to its order in the variables*. Under linear transformation of its variables, every form undergoes also a reverse linear transformation of its coefficients, determined or *induced* by that of the variables. These need not be described more minutely here; they require for precise statement the definition of *polars*. (See POLE and POLAR.) While the two forms are called equivalent when the equations that transform variables are given, to make the statement algebraically exact the coefficients of similar terms in the two forms must be equated, and these equations constitute the induced substitution. But two forms may be given with numerical coefficients. By what means may their equivalence be tested? This is the first major problem in algebraic form theory. The answer is far from complete. Sufficient conditions can be stated, but many of them are certainly redundant. The minimum set of necessary conditions is known in only a few particular cases. To find explicitly the parameters of a linear substitution from the equations of the induced substitution on the coefficients would require the solving of equations whose degree in the parameters is equal to that of the given forms in the proper variables. That calls for extraction of roots or other irrational operations. Naturally an answer is preferred which should demand only rational operations in proving equivalence or non-equivalence. Hence comes a re-formulation of the question: When two forms (or systems of forms) are equivalent, what rational functions of the coefficients, or coefficients and variables, will have the same numerical value for both forms? What rational functions of coefficients and variables retain the same value, remain invariant, under the group of linear substitutions? This question can be answered. As an exercise, the reader might verify that two binary cubics are generally equivalent, but not always two binary quartics, taken at random.

Invariant and Covariant.—An invariant or covariant (a comitant) of a given form or system is any function of the coefficients, or coefficients and variables, which is identically equal to the same function of the corresponding coefficients and variables in every equivalent form or system—equal, that is, save for a multiplicative constant depending on the parameters of the transformation. Such a constant, it can be proved, is always some power of the determinant of the substitution. These are relative invariants, but if the multiplicative constant is unity, the invariant is absolute.

BINARY FORMS

The rational invariants of a single binary form of order less than ten have been thoroughly studied and tabulated. First to be noticed was naturally the discriminant or determinant of a quadric form, for it was known to vanish when the quadric has two equal factors; and their equality could not be altered by linear transformations, therefore the determinant after transformation must be a multiple of that before the transformation. To verify this, take the quadric $ax_1^2 + 2bx_1x_2 + cx_2^2$, the discriminant of which is $D = 4b^2 - 4ac$. The transformation is given by the equations:—

$$x_1 = \alpha_1 y_1 + \beta_1 y_2, \quad x_2 = \alpha_2 y_1 + \beta_2 y_2.$$

The transformed quadric is

$$\begin{aligned}&(a\alpha_1^2 + 2b\alpha_1\alpha_2 + c\alpha_2^2)y_1^2 \\&+ 2(a\alpha_1\beta_1 + b(\alpha_1\beta_2 + \alpha_2\beta_1) + c\alpha_2\beta_2)y_1y_2 \\&+ (a\beta_1^2 + 2b\beta_1\beta_2 + c\beta_2^2)y_2^2.\end{aligned}$$

The new coefficients are, therefore,

$$\begin{aligned}a' &= a\alpha_1^2 + 2b\alpha_1\alpha_2 + c\alpha_2^2, \\b' &= a\alpha_1\beta_1 + b(\alpha_1\beta_2 + \alpha_2\beta_1) + c\alpha_2\beta_2, \\c' &= a\beta_1^2 + 2b\beta_1\beta_2 + c\beta_2^2.\end{aligned}$$

For the discriminant after the transformation we find

$$\begin{aligned}D' &= 4b'^2 - 4a'c' \\&= (\alpha_1\beta_2 - \alpha_2\beta_1)^2 \cdot D.\end{aligned}$$

This invariant D is the only one that the quadric has. The binary cubic and quartic have covariants as well as invariants, easily discovered without an elaborate notation. First, it should

be observed that symbols of differentiation, $\frac{\partial}{\partial x_1}$ and $\frac{\partial}{\partial x_2}$, undergo a so-called *transposed* substitution, thus:—

$$\begin{aligned}\frac{\partial}{\partial x_1} &= \frac{1}{\Delta} \left(\beta_2 \frac{\partial}{\partial y_1} - \alpha_2 \frac{\partial}{\partial y_2} \right) \\ \frac{\partial}{\partial x_2} &= \frac{1}{\Delta} \left(-\beta_1 \frac{\partial}{\partial y_1} + \alpha_1 \frac{\partial}{\partial y_2} \right), \quad \Delta = (\alpha_1\beta_2 - \alpha_2\beta_1).\end{aligned}$$

(See DETERMINANT.) The law for multiplication of determinants shows then a factoring, if ϕ and ψ denote any two forms:

$$\begin{vmatrix} \frac{\partial \phi}{\partial x_1} & \frac{\partial \phi}{\partial x_2} \\ \frac{\partial \psi}{\partial x_1} & \frac{\partial \psi}{\partial x_2} \end{vmatrix} = \frac{1}{\Delta^2} \begin{vmatrix} \beta_2 - \alpha_2 \\ -\beta_1 & \alpha_1 \end{vmatrix} \cdot \begin{vmatrix} \frac{\partial \phi}{\partial y_1} & \frac{\partial \phi}{\partial y_2} \\ \frac{\partial \psi}{\partial y_1} & \frac{\partial \psi}{\partial y_2} \end{vmatrix} = \frac{1}{\Delta} \begin{vmatrix} \frac{\partial \phi}{\partial y_1} & \frac{\partial \phi}{\partial y_2} \\ \frac{\partial \psi}{\partial y_1} & \frac{\partial \psi}{\partial y_2} \end{vmatrix}.$$

This shows that the Jacobian of any two forms is a covariant.

But the two forms may be $\frac{\partial f}{\partial x_1}$ and $\frac{\partial f}{\partial x_2}$. Then the covariant is termed the *Hessian* of the form f : $f = ax_1^3 + 3bx_1^2x_2 + 3cx_1x_2^2 + dx_2^3$

$$H = \frac{1}{36} \begin{vmatrix} \frac{\partial^2 f}{\partial x_1^2} & \frac{\partial^2 f}{\partial x_1 \partial x_2} \\ \frac{\partial^2 f}{\partial x_2 \partial x_1} & \frac{\partial^2 f}{\partial x_2^2} \end{vmatrix} = (ac - b^2)x_1^2 + (ad - bc)x_1x_2 + (bd - c^2)x_2^2.$$

The Jacobian of f and H is also covariant, of order three:—

$$Q = \frac{1}{6} \begin{vmatrix} \frac{\partial f}{\partial x_1} & \frac{\partial f}{\partial x_2} \\ \frac{\partial H}{\partial x_1} & \frac{\partial H}{\partial x_2} \end{vmatrix} = (a^2d - 3abc + 2b^3)x_1^3 +, \text{ etc.}$$

These four functions, all well known in the theory of equations, are connected by an identical relation or *syzygy*: $Q^2 + 4H^3 + Rf^2 = 0$. This shows that $Q + f\sqrt{-R}$ and $Q - f\sqrt{-R}$ are perfect third powers of the factors of H .

The Binary Quartic, $f = ax_1^4 + 4bx_1^3x_2 + 6cx_1^2x_2^2 + 4dx_1x_2^3 + ex_2^4$ is more interesting and not too complicated. It has one absolute invariant, which is the ratio of two relative invariants, i and j , and two covariants, H and T .

Their explicit formulae are:—

$$i = ae - 4bd + 3c^2, \quad j = \begin{vmatrix} a & b & c \\ b & c & d \\ c & d & e \end{vmatrix},$$

$$H = \frac{1}{144} \begin{vmatrix} \frac{\partial^2 f}{\partial x_1^2} & \frac{\partial^2 f}{\partial x_1 \partial x_2} \\ \frac{\partial^2 f}{\partial x_2 \partial x_1} & \frac{\partial^2 f}{\partial x_2^2} \end{vmatrix}, \quad T = \frac{1}{8} \begin{vmatrix} \frac{\partial f}{\partial x_1} & \frac{\partial f}{\partial x_2} \\ \frac{\partial H}{\partial x_1} & \frac{\partial H}{\partial x_2} \end{vmatrix}.$$

These five forms are connected by an identity or *syzygy*, $T^2 + 4H^3 - iHf^2 + jf^3 = 0$.

From this comes an important factorization, if the cubic equation, $4z^3 - iz + j = 0$, has three roots m_1, m_2, m_3 , namely:—

$$T^2 = -4(H - m_1f)(H - m_2f)(H - m_3f),$$

the factors on the right are perfect squares, a fact which aids in solving the quartic equation. The discriminant R is expressible in terms of i and j : $R = i^3 - j^2$. When $R = 0$, f and H have each a double factor, while T has one five-fold factor. If further i and j are both zero, the quartic f has a triple factor, and that factor occurs in H to the fourth power. Were H to vanish identically, f must be a perfect fourth power. (If H' is formed from H as H is from f , and T' from H and H' as T is from f and H , then T' differs from T only by an invariant factor.)

These details show that, for forms of higher order and in more than two variables, invariants would be unwieldy if written out in full. An abbreviated notation is a necessity for the development of the theory. The most generally used are the hyperdeterminant notation of Arthur Cayley, the Clebsch-Aronhold notation, which is practically the same, and modifications of either. Aronhold, R. F. A. Clebsch and Gordan use the following, some slight improvements having been made by E. Study.

TERNARY FORMS

If three ternary linear forms vanish for the same values of the variables, not all zero, *i.e.*, if

$$\begin{aligned} a_1x_1 + a_2x_2 + a_3x_3 &= 0 \\ b_1x_1 + b_2x_2 + b_3x_3 &= 0 \\ c_1x_1 + c_2x_2 + c_3x_3 &= 0, \end{aligned}$$

then their determinant, denoted by $(a_1b_2c_3)$ or merely (abc) , is zero. No linear transformation will disturb this relation, hence (abc) is an invariant of the three linear forms. It is the type of all invariant combinations of symbols. If the forms are abbreviated to (ax) , (bx) and (cx) respectively, and written with different sets of variables, *e.g.*, (ax) , (by) , (cz) , then (abc) is, in another expression:—

$$\begin{vmatrix} \frac{\partial}{\partial x_1} & \frac{\partial}{\partial x_2} & \frac{\partial}{\partial x_3} \\ \frac{\partial}{\partial y_1} & \frac{\partial}{\partial y_2} & \frac{\partial}{\partial y_3} \\ \frac{\partial}{\partial z_1} & \frac{\partial}{\partial z_2} & \frac{\partial}{\partial z_3} \end{vmatrix} (ax) (by) (cz).$$

This suggests that if ternary forms of higher order are expressed symbolically as powers of linear forms, operators of this same type, denoted by $\left(\frac{\partial}{\partial x} \frac{\partial}{\partial y} \frac{\partial}{\partial z}\right)$, acting on a collection of

such forms would produce invariants. The property of invariance is now located in the elementary operator. A single form may be represented by several symbols in the same problem; a ternary quadric, by $(ax)^2$, $(bx)^2$ and $(cx)^2$ indifferently. Then the operation $\left(\frac{\partial}{\partial x} \frac{\partial}{\partial y} \frac{\partial}{\partial z}\right)^2 (ax)^2 (by)^2 (cz)^2$ will yield, when explicated,

$$2 \begin{vmatrix} a_1 & a_2 & a_3 \\ b_1 & b_2 & b_3 \\ c_1 & c_2 & c_3 \end{vmatrix}^2 \text{ or } 2(abc)^2.$$

This result, if not identically equal to zero, is an invariant of the ternary quadric; in fact, its discriminant. An invariant so symbolized can be translated into terms of the actual coefficients of the quadric if we agree that $(ax)^2$ shall mean

$$\sum_1^3 a_{ii} x_i^2 + \sum_{i,k=1, i \neq k}^3 a_{ik} x_i x_k$$

and that $a_{ik} = a_{ki}$. Further, any symbolic product a_1a_2 means a_{12} , and a_2^2 means a_{22} . Similar conventions yield, for a ternary cubic $(ax)^3$, $(bx)^3$, $(cx)^3$ or $(dx)^3$, the invariant:— $(abc)(abd)(acd)(bcd)$, which is one of the two well-known invariants of the cubic. It is obvious also that $(abc)^2(ax)(bx)(cx)$ will be a symbol of a covariant of the cubic form; it is commonly called the *Hessian* of the cubic.

Such a structure might, however, prove to signify identically zero when symbols are translated into actual coefficients. Such cases are $(abc)^3$ and $(abc)^2(ade)(bde)(cde)$. Again, the difference of two supposed invariant forms may be a zero form, in which case the expressions, apparently distinct, signify actually the same invariant. Ambiguity of expression results from the existence of zero forms, and these in turn from a few elementary identities which are essentially alike. For binary covariants containing not more than two sets of variables, these identities are combinations of the following three:—

$$\begin{aligned} (ab)(cx) - (ac)(bx) + (bc)(ax) &= 0, \\ (ab)(xy) - (ax)(by) + (bx)(ay) &= 0, \\ (ab)(cd) - (ac)(bd) + (bc)(ad) &= 0, \end{aligned}$$

whatever the symbols may represent.

Equally recognizable is the possible ambiguity of symbolic formulae in invariants of ternary forms. The typical identity is this:—

$$(abc)(dx) - (abd)(cx) + (acd)(bx) - (bcd)(ax) = 0,$$

or this:—

$$(abc)(def) - (abd)(cef) + (abe)(cdf) - (abf)(cde) = 0.$$

Geometric Considerations.—For geometric uses variables of a second kind are considered. These are line co-ordinates $(u_1u_2u_3)$, subject to *contragredient* linear transformations so adjusted to those of the *point co-ordinates* $(x_1x_2x_3)$ that, if the latter are expressed in terms of $(y_1y_2y_3)$, and the former in terms of $(v_1v_2v_3)$, then identically

$$(ux) = u_1x_1 + u_2x_2 + u_3x_3 = v_1y_1 + v_2y_2 + v_3y_3 = (vy).$$

The combination (ux) is called the identical covariant. Symbols a_1b_1 etc. are cogredient with the u 's. When variables u and variables x are present in the same covariant expression, the above zero form may be

$$(abc)(ux) - (abu)(cx) + (acu)(bx) - (bcu)(ax) = 0,$$

or $(abc)(deu) - (abd)(ceu) + (abe)(cdu) - (abu)(cde) = 0$.

GENERAL LAWS OF STRUCTURE

The first major problem in the theory of forms is the determination of general laws for structure of invariants. For *binary*

forms containing one set of variables it is proved that invariant forms consist of a finite number of terms composed of symbolic factors like (ab) and (ax) . For a ternary form structure of invariant forms, invariant comitants in one set of variables (x) and one set of contragredient variables (u) , every invariant concomitant consists solely of terms containing symbolic factors of these types: (ux) , (abc) , (ax) , (abu) . Equivalent symbolic representations of any one invariant form differ by a form containing in each term one or more of the above listed zero factors. Starting from more than one fundamental form, more types of symbolic factors would be admitted; so also if a fundamental form contains both kinds of variables, x 's and u 's.

Set of Three Quadrics.—Among ternary forms, after quadrics and systems of two quadrics, the next in point of simplicity and geometric interest is the set of three quadrics, or, what is closely related to such a set, the ternary cubic. If all invariants, covariants and contravariants are considered, together with mixed comitants containing both sets of variables, $(x_1x_2x_3)$ and $(u_1u_2u_3)$, then 34 distinct forms constitute a complete system for the rational expression of all others. The best known of these are, for the cubic f written symbolically $f = (ax)^3, (bx)^3, (cx)^3$, etc.:—

Hessian covariant, $H = (abc)^2 (ax) (bx) (cx)$;
invariant, $S = (abc) (abd) (acd) (bcd)$;
invariant, $T = (abc)^2 (ade) (bdf) (cef) (def)$;
contravariant $\Sigma = (abc) (abu) (acu) (bcu)$, ("Cayleyan");
contravariant $T = (abc)^2 (ade) (bdu) (ceu) (deu)$;
discriminant $(T^2 - \frac{1}{6} S^3)$;
mixed form $\Theta = (abu)^2 (ax) (bx)$;
doubly apolar contravariant, $\Pi = 6T\Sigma - 4ST$.

This contravariant Π is noteworthy as being strictly dual to f itself; i.e., if variables (u) and (x) are exchanged, and invariants and contravariants derived from the altered Π , as from f , then the new Π altered by the same exchange of variables would be a multiple of the old f . The discriminant of H contains as a factor the discriminant of f . This has led to the discovery of closed systems among the comitants of the system,—closed with respect to the action of an operator δ , the "Aronhold operation." Denote in actual coefficients the two cubics—

$$f = \sum_{i+j+k=3} a_{ijk} x_1^i x_2^j x_3^k, \quad H = \sum_{i+j+k=3} \alpha_{ijk} x_1^i x_2^j x_3^k,$$

then the operation δ is defined thus (for this particular theory),

$$\delta = \Sigma \left(\alpha_{ijk} \frac{\partial}{\partial a_{ijk}} \right); \text{ i. e., } \delta f \equiv H.$$

Then it is found that

$$\begin{aligned} \delta H &= \frac{1}{2} S \cdot f \\ \delta S &= 4T, & \delta T &= S^2, \\ \delta \Sigma &= 3T, & \delta T &= \frac{1}{6} S \cdot \Sigma, \end{aligned}$$

and connections are discovered among mixed forms of like orders.

For a ternary form of order four, the minimum number of covariant forms in a basis has not been determined; one author, Miss E. Noether, has progressed so far in approximations as to prove that it is above 300. For simultaneous systems of a small number of quadrics such work has been carried to a finish; but for higher orders it would be sport rather than science. Connections are soonest found among forms of low degrees.

Irrational Invariants are such as satisfy equations, algebraic, differential or functional, with invariant or covariant coefficients. Forms apolar to a given form satisfy an equation linear in their coefficients; e.g., the doubly apolar cubics f and Π mentioned above, so Hilbert's form $\phi = (ax)^3$, irrationally covariant to a cubic $(ax)^3$, satisfies an equation $(abx)^2(ax) (bx) \equiv M(ax)^2$, a relation discussed in vol. i of the *Transactions of the American Mathematical Society*. "Binary quartics which are multiples of their own Hessian covariants are the squares of quadrics." Combinants and semicombinants furnish another illustration. A

combinant of two forms of like order, $(ax)^n$ and $(Ax)^n$ is any simultaneous covariant of the two which is unchanged, save for a factor, when the first two are replaced by $m_1(ax)^n + M_1(Ax)^n$ and $m_2(ax)^n + M_2(Ax)^n$, m_1 and m_2 , M_1 and M_2 denoting any constants. One such is their Jacobian, and all others are comitants of that Jacobian, $(Aa) (Ax)^{n-1} (ax)^{n-1}$. A semicombinant of two forms of different orders is unchanged when the form of higher order is replaced by a homogeneous combination; e.g., when binary $(ax)^4$ and $(Ax)^3$ are replaced by $(ax)^4 + (m_1x_1 + m_2x_2) (Ax)^3$ and $(Ax)^3$. These are conjectured to be useful in discussing intersections of plane curves, or of surfaces, of different orders.

Classification.—Degree and order give a two-way arrangement, *order* being the number of variable factors in every term of the homogeneous covariant; degree, the number of factors which are coefficients of the fundamental form. One problem is, to enumerate the different invariant forms of a specified order and degree, counting as one any two whose difference is a zero-form. This counting gives a result that increases rapidly with the degree. But invariants of lower degree can be combined, in rational integral aggregates, into such of higher degree. This indicates a reduction at each stage of the enumeration by discarding those rational and integral in lower stages. Will the final result be zero at and beyond some finite degree? It proves to be so for all forms of low order in the binary field, and for systems of two or three ternary quadrics. The third major problem is, then, that of the finiteness of reduced systems of invariant comitants.

ORDERLY PRODUCTION AND ENUMERATION

The second major problem is that of orderly production and enumeration. The internal structure of all invariant forms is known; and all that involve a given fundamental form or system, in a given degree, and one or more sets of variables to specified orders, can be written down mechanically. There will be some ambiguity, i.e., repetitions, owing to the zero forms. The third great problem concerning the totality of such invariants is commonly called Gordan's problem; from Paul Gordan who in 1869 was the first to solve it for binary forms. The question arises, is there a finite basis for the entire system F_1, F_2, \dots, F_l in terms of which all others can be represented linearly? If F is any invariant not in that basis, is there an identical equation

$$F \equiv q_1 F_1 + q_2 F_2 + \dots + q_{l-1} F_{l-1} + q_l F_l$$

with coefficients $q_1, q_2, \dots, q_{l-1}, q_l$ polynomials in the variables x_1, x_2 ? Gordan's various proofs, that this basis must always exist, appeared first in 1869, later, revised, in 1871, and subsequently. His proof was based on the nature of certain elementary operations which build up and knit together those invariant forms; more precisely, on the Gordan series developing a form in terms of polars and Cayleyan operations. This is given in somewhat improved form by Grace and Young (*The Algebra of Invariants*, 1903). As Jacques Deruyts has gone further, treating the enumeration problem for forms in any number of variables, and as the question of finite systems is treated with greater generality by Hilbert, the earlier methods need not be exhibited. Deruyts's method is generalized from that for binary forms used by Arthur Cayley, James J. Sylvester and Fabian Franklin; Hilbert's was entirely novel.

Semi-invariants as Sources of Invariant Forms.—Semi-invariant had been defined by Cayley and Sylvester, for binary forms, as a polynomial in coefficients and variables of one or more fundamental forms, whose specific property it is to remain unaltered (identically) when the variables undergo the substitution

$$\begin{aligned} x_1 &= y_1 + \lambda y_2, \\ x_2 &= y_2, \end{aligned}$$

and the coefficients undergo the corresponding linear transformation, the variables (y) being replaced afterwards by (x) . Deruyts applies the same term to functions in more than two variables, unaltered by any substitution whose determinant lacks all con-

stituents below the principal diagonal. For quaternary forms such a substitution is this:—

$$\begin{aligned}x_1 &= y_1 + \alpha y_2 + \beta y_3 + \gamma y_4 \\x_2 &= y_2 + \delta y_3 + \epsilon y_4 \\x_3 &= y_3 + \theta y_4 \\x_4 &= y_4.\end{aligned}$$

Like Alfredo Capelli, he considers for a quaternary system, covariants which may contain three sets of cogredient variables $(x_1 x_2 x_3 x_4)$, $(y_1 \dots y_4)$, $(z_1 \dots z_4)$. Clebsch and Gordan had employed instead three unlike sets, two mutually contragredient, the other intermediate, its substitution like that of two-rowed determinants in either of the first two sets. If a covariant contains, when written in Clebsch-Aronhold symbols, π determinant factors in every term, and is of orders m_1 in the (x) , m_2 in the (y) , m_3 in the (z) , (where $m_1 \geq m_2 \geq m_3$), its weights are called $\pi_1 = \pi + m_1$, $\pi_2 = \pi + m_2$, $\pi_3 = \pi + m_3$, $\pi_4 = \pi$; then it is shown that every *primary covariant* can be derived uniquely from a semi-invariant as source, which contains in every term

$$\begin{aligned}\pi_4 & \text{ 4-rowed symbolic determinant factors like } (a_1 b_2 c_3 d_4); \\ \pi_3 - \pi_4 & \text{ 3-rowed determinant factors with subscripts 1, 2, 3, like } (a_1 b_2 c_3); \\ \pi_2 - \pi_3 & \text{ 2-rowed determinant factors with subscripts 1, 2, like } (a_1 b_2); \\ \pi_1 - \pi_2 & \text{ monomial factors like } a_1, b_1, \text{ etc.}\end{aligned}$$

The number of such sources that can be written for a given set of weights $\pi_1, \pi_2, \pi_3, \pi_4$, may be denoted by $\{\pi_1, \pi_2, \pi_3, \pi_4\}$ but is subject to reduction.

This precisely defined structure of a semi-invariant is the clue to the problem: how many semi-invariants of given weights $\pi_1, \pi_2, \pi_3, \pi_4$ are linearly independent? For it is possible to count, directly or by formulae, the number of different monomial expressions, rational and entire in the coefficients, which have the prescribed weights. As they are expressed in actual coefficients (not symbolic merely) they are linearly independent. Next, they are required to satisfy the three differential equations expressing invariance under the one-way substitutions (21), (32), (43), which change the weights respectively to $(\pi_1 + 1, \pi_2 - 1, \pi_3, \pi_4)$, $(\pi_1, \pi_2 + 1, \pi_3 - 1, \pi_4)$, $(\pi_1, \pi_2, \pi_3 + 1, \pi_4 - 1)$. These involve as many conditions as there are terms of such weights; hence their number is to be subtracted from the first estimate. Then the overlapping conditions must be considered, etc. In all, the enumeration calls for as many items, additive and subtractive, as there are terms in a four-rowed determinant. This statement is for forms homogeneous in four variables. Were the forms binary, only two weights and two types of factors in semi-invariants would occur, and the results would be those of Sylvester and Franklin. For invariants (free from variables) of forms in any number of variables, the weights for the first distribution are all equal, and the calculation therefore slightly easier. But whatever the orders in variables, after the enumeration for linearly independent comitants comes the reduction for those composed of rational factors, factors which are themselves covariants of the same or lower orders. This is the "tamisage" of Sylvester and Franklin.

FINITENESS OF SYSTEM OF INVARIANTS: HILBERT'S EXTENSIONS

The *third major problem* is concerned with the finiteness of reduced systems of invariant comitants. Reduction by tamisage may show that, for degrees and orders proposed, all covariants are reducible, i.e., rationally expressible in terms of those of lower degrees. Beyond certain upper limits this must always occur. While Gordan and others proved this for binary forms, Hilbert established it for any finite number of forms in any finite number of variables. His widely inclusive principal theorem relates to algebraic forms, homogeneous, rational and integral

in the elements of any number of independent systems. Now invariants, as here defined, are so constructed from one or more sets of variables strictly so called, and from the coefficients of one fundamental form or from those of several independent forms. The theorem states, "If a series of forms be given, rational and integral and homogeneous in a domain of a finite number of finite sets of elements (variables or parameters), then it is always possible to find a finite *basis*, or set of forms among those given, such that every other form in the given (finite or infinite) series shall be expressible linearly in terms of those basal forms, with coefficients rational and integral in the same domain." The proof is by mathematical induction, from forms in n variables to forms in $n+1$ variables, with starting-point in the obvious truth of the statement when a single variable x is concerned. It proceeds upon the lemma that a linear function of linear functions of several variables is itself a linear function of those variables.

According to this theorem of Hilbert's, if the given series of invariants be denoted by A_1, A_2, \dots arranged in ascending degrees in sets of parameters concerned, then among the A 's is contained a basal set $B_1, B_2, \dots B_k$, such that every A is expressible thus:—

$$A_i = M_{i1}B_1 + M_{i2}B_2 + \dots + M_{ik}B_k,$$

the M 's being rational in the same domain as the given A 's. But more than this is true: the M 's, if not invariants, can be replaced by invariants, which in turn are either B 's, or expressible in the B 's just as the A 's which include them. To turn the M 's into invariants while leaving A 's and B 's unchanged is an operation most neatly carried out by Mertens' device, as follows (confining the treatment to ternary forms, for brevity):—

Assume any linear transformation of the variables involved, say x_1, x_2, x_3 , and cogredient sets, with indeterminate parameters $\alpha_1, \alpha_2, \alpha_3, \beta_1, \dots, \gamma_1, \dots, \gamma_3$, viz.,

$$\begin{aligned}x_1 &= \alpha_1 y_1 + \beta_1 y_2 + \gamma_1 y_3 \\x_2 &= \alpha_2 y_1 + \beta_2 y_2 + \gamma_2 y_3 \\x_3 &= \alpha_3 y_1 + \beta_3 y_2 + \gamma_3 y_3.\end{aligned}$$

Calculate the induced transformations, resulting from this, upon the coefficients of the one or more fundamental forms. Those will give the old set of coefficients rationally in terms of the new, with denominators some powers of the determinant $(\alpha_1 \beta_2 \gamma_3)$ or Δ . Every M is thereby expressed as a form in the given domain and in the parameters (α) , (β) , (γ) ; so also the B 's, and these become merely powers of Δ multiplied into functions of quantities exclusive of the (α) , (β) and (γ) . Now perform on every A_i, B_k and M_{ik} the operation P^{π_i}

$$P = \begin{vmatrix} \frac{\partial}{\partial \alpha_1} & \frac{\partial}{\partial \alpha_2} & \frac{\partial}{\partial \alpha_3} \\ \frac{\partial}{\partial \beta_1} & \frac{\partial}{\partial \beta_2} & \frac{\partial}{\partial \beta_3} \\ \frac{\partial}{\partial \gamma_1} & \frac{\partial}{\partial \gamma_2} & \frac{\partial}{\partial \gamma_3} \end{vmatrix}$$

where π_i is the weight of the invariant A_i . Every A_i and B_k reappears multiplied by a numerical constant (some power of 6); every M_{ik} yields an invariant and a numerical factor, and the identity is undisturbed. Accordingly, by repetitions if necessary, every A_i is expressible in terms of products of B 's with purely numerical coefficients.

Powers and products of powers of the B_k constitute a subset among the A_i . The same argument applies to them, giving a second theorem due to Hilbert. There exist an unlimited series of identities among the products of powers of the basal invariants of a system, identically true when all are explicit in the original variables and coefficients of given forms. These identities are called *syzygies*, and when all significant terms are brought to one side of the identity, that side (as a function of the B_k) is a *syzygant* of the first kind among the invariants B_k . Among the syzygants of the first kind there exist then syzygants of the second

kind, etc. But by a third theorem of Hilbert's the number of kinds of syzygants upon a given system of invariants is itself a finite number. Little has been done in concrete illustration of these theorems, or in the substitution of precise limits for the "finite" numbers involved; though Hilbert himself fixed an upper bound for the number of kinds of syzygies when m is the number of independent forms in the basis of the modulus or system, and worked out details for the system of three quadric surfaces defining a twisted cubic curve.

APOLARITY

For geometry, co-ordinates or variables all of one kind are not sufficient. The theory of duality demands, in a plane, point co-ordinates and line co-ordinates; and, in three-space, points and planes are dual, while lines, dual to lines, require a third kind of co-ordinates. A *polarity* of two forms is then an important relation. Ternary forms in contragredient sets of variables (x) and (u) are defined as apolar by the aid of an operator

$$\left(\frac{\partial}{\partial x_1} \cdot \frac{\partial}{\partial u_1} + \frac{\partial}{\partial x_2} \cdot \frac{\partial}{\partial u_2} + \frac{\partial}{\partial x_3} \cdot \frac{\partial}{\partial u_3} \right), \text{ or } \left(\frac{\partial^2}{\partial x \partial u} \right).$$

In binary forms, if $(x_1: x_2)$ and $(y_1: y_2)$ are cogredient, then $(x_1: x_2)$ and $(-y_2: y_1)$ are contragredient sets, and the operator

for apolarity is $\left(\frac{\partial}{\partial x_1} \frac{\partial}{\partial y_2} - \frac{\partial}{\partial x_2} \frac{\partial}{\partial y_1} \right)$. Two forms $(ax)^n$, $(uA)^n$

of like order are simply, doubly, etc. apolar if

$$(aA)^n = 0, \text{ i.e. } \left(\frac{\partial^2}{\partial x \partial u} \right)^n (ax)^n (uA)^n = 0,$$

or if $(aA)^{n-1}(ax)(uA) = 0$, i.e. $\left(\frac{\partial^2}{\partial x \partial u} \right)^{n-1} (ax)^n (uA)^n = 0$

(for all x and u).

Important applications of this notion to binary forms are connected with canonical or normal forms of quantics of odd order, and with a special kind of quantic of even order. A binary quantic of even order $(ax)^{2n}$, is equivalent to a sum of n perfect $2n$ th powers of linear forms if its catalecticant vanishes. A $(2n+1)$ -ic is reducible to the sum of $n+1$ perfect $(2n+1)$ th powers of linear forms, the linear factors of the canonizant. As to the latter, if the given form is

$$f(x_1, x_2) = (ax)^{2n+1} = \sum_1^{n+1} p_i (\alpha_{i1} x_1 + \alpha_{i2} x_2)^{2n+1},$$

and the canonizant

$$(Ax)^{n+1} = \prod_1^{n+1} (\alpha_{i1} x + \alpha_{i2} x_2),$$

then the transvectant

$$\frac{n!}{(2n+1)!} (Ax)^{n+1} (ay)^n = \sum p_i (\alpha_i y)^n \cdot \prod_1^{n+1} (\alpha_{i1} \alpha_{k_2} - \alpha_{k_1} \alpha_{i2}) = 0$$

is identically $= 0$ on account of $n+1$ zero factors in which $i=k$. From the $n+1$ implied equations of condition, and from $(Ax)^{n+1} = 0$, elimination of the $n+2$ coefficients of $(Ax)^{n+1}$ yields the canonizant in the form of a determinant. This must be resolved into its linear factors, which must all be distinct, and then the $n+1$ coefficients p_i can be determined from linear equations.

For a binary form of even order, $(ax)^{2n}$, similar reasoning shows that it is reducible to the sum of $n+1$ perfect $2n$ th powers of linear forms, one of them an arbitrary linear form; or to the sum of n such powers if a determinant of n rows, the *catalecticant*, is equal to zero.

The so-called typical representation of binary forms expresses forms of odd order in terms of any two linear covariants, with coefficients automatically invariant. The symbolic identity $[(\alpha\beta) \cdot (ax)]^n = [(\alpha\beta) (\alpha x) - (\alpha\alpha) (\beta x)]^n$ exhibits this, when (αx)

and (βx) are the selected covariants. For a binary form of even order three quadric covariants are needed, and these can be found if the order is foregoing four; call them $(\alpha x)^2$, $(\beta x)^2$, $(\gamma x)^2$, and the form $(ax)^{2n}$. Then the expansion of a four-rowed determinant gives an identity in the symbol $(ax)^2$, and an n th power yields the desired typical representation:—

$$\begin{vmatrix} (ax)^2 & \alpha_1^2 & \alpha_1 \alpha_2 & \alpha_2^2 \\ (\alpha x)^2 & \alpha_1^2 & \alpha_1 \alpha_2 & \alpha_2^2 \\ (\beta x)^2 & \beta_1^2 & \beta_1 \beta_2 & \beta_2^2 \\ (\gamma x)^2 & \gamma_1^2 & \gamma_1 \gamma_2 & \gamma_2^2 \end{vmatrix} = A(ax)^2 - \{B(\alpha x)^2 + C(\beta x)^2 + D(\gamma x)^2\}, \\ = 0$$

whence $A^n(ax)^{2n} = \{B(\alpha x)^2 + C(\beta x)^2 + D(\gamma x)^2\}^n$.

The linear covariants constitute a most interesting meeting point of geometry and algebra. (F. Morley in *Math. Ann.* vol. 49.)

The foregoing example of an even form and quadric covariants is also an example of geometric picturing of a binary form and its comitants upon a rational algebraic curve in two or more dimensions,—in this case on a curve of the second order in a plane. For, if we set $\xi_1/(\alpha x)^2 = \xi_2/(\beta x)^2 = \xi_3/(\gamma x)^2$, elimination of $x_1: x_2$ gives the equation of a conic in $\xi_1: \xi_2: \xi_3$, while $(ax)^{2n}$ is transformed into a ternary n -ic, and this, equated to zero, cuts out, on that conic, a set of $2n$ points, the picture of the $2n$ zero points of $(ax)^{2n}$ in the binary domain. Further, a unique curve of order n , can be determined, cutting out those $2n$ points on the conic, and itself apolar to the conic. Some use has been made of this style of picturing both on the plane conic and on the *gauche* curve of order three in three-space. (F. Meyer, *Apolarität und rationale Curven*, Tübingen, 1883.)

A sample of the relations, more easily discoverable in such geometric pictures than in algebraic symbols, is this theorem on three binary quadrics. Any three linearly independent quadrics being given (no one of which is the Jacobian of the two others), every fourth quadric is linearly related to them, with constant coefficients. But there is a unique fourth quadric, determined by the requirement that its square shall be a linear combination of the squares of the first three, with constant coefficients. Then any three of these four quadrics, taken in pairs, determine three Jacobians or functional determinants, covariant quadrics, which are related to the fourth of the original set in the same way as are the first three. (Meyer, *Apolarität und rationale Curven*, p. 244.) That is, if we use f_1, f_2, f_3, f_4 to denote the four quadrics, and write J_{12} , for example, for the Jacobian of f_1 and f_2 ,—

$$J_{12} = \begin{vmatrix} \frac{\partial f_1}{\partial x_1} & \frac{\partial f_1}{\partial x_2} \\ \frac{\partial f_2}{\partial x_1} & \frac{\partial f_2}{\partial x_2} \end{vmatrix}$$

then if there is an identical relation

$$f_4^2 = m_1 f_1^2 + m_2 f_2^2 + m_3 f_3^2,$$

the m 's denoting numbers, then there will be also an identical relation

$$f_4^2 = k_1 J_{23}^2 + k_2 J_{31}^2 + k_3 J_{12}^2.$$

This is more interesting when it is noticed that the f 's are necessarily proportional to the Jacobians of the J 's:—

$$J(J_{12}, J_{23}) : J(J_{23}, J_{31}) = f_2 : f_3, \text{ etc.},$$

for then it exhibits connections in a finite closed system.

HISTORICAL NOTE

Prior to the year 1800 the study of algebraic forms was confined to questions of factors, multiples, powers, differentiation and elimination. Resultants, discriminants and in particular determinants were chief objects of interest. Early in the 19th century, however, the invention or formulation of projective geometry and the study of groups in the theory of equations drew attention to the operational character of mathematics as

distinguished from its static aspect. It cannot be regarded as purely accidental that algebra, with its abstract groups of transformations, followed after and eventually outran geometry with its groups of projectivities and quadric inversions. Projective geometry had been systematized and largely created between 1813 and 1840 by Jean Victor Poncelet, Plücker and M. Chasles. In 1841 the germ of a new movement in algebra appears when George Boole noticed that the discriminant of $q + \lambda Q$, a homogeneous form with one parameter, must be a multiple of the discriminant of the same after transformation $q' + \lambda Q'$; from this follows that the discriminant is an invariant. In the same year appeared an essay of C. G. J. Jacobi on functional determinants, emphasizing their invariance under linear substitutions. In 1842 Boole announced the invariance of polars. Three years later Cayley subsumed what was already known, and opened a new field of discovery, in the publication of his calculus of hyperdeterminants. This was in his view simply an extension, to symbols, of the theorem on multiplication of determinants of like order whose constituents are actual numbers. This was in 1845; but already in 1844 had been published Friedrich G. M. Eisenstein's development of the invariants of a binary cubic and quartic, and Hesse's first paper on the covariant now universally known as the Hessian. Aronhold (1849) found the invariants of the ternary cubic, and their combination in the discriminant. Sylvester's 40 years' labour in this field opened in 1851, and within four years he had invented most of the technical terminology and tapped most of the rich veins of the mines of the theory of invariants. He had even then shown the invariance of resultants under substitutions of higher order, and had given examples of combinants, and had named the catalecticant.

Charles Hermite's contributions began in 1851 with his discovery of evectants, followed not long after by his law of reciprocity for invariants of binary forms, and by explicit formulae for the transformations of a quadric form into itself. Several writers realized the value of the differential equations of invariance and covariance (at present perhaps the most emphasized point of departure for the entire theory); among these were Francesco Brioschi, Sylvester and Cayley. The reference of invariant forms to *sources* is found first in the work of M. Roberts (1861), who proved, for binary forms, that the source of a product of covariants is the product of their several sources. Non-Euclidean geometry was attached to the algebraic train by Cayley (1859).

Meantime the new algebra had become accessible to wider circles by Salmon's publication of his *Higher Plane Curves* (1852) and *Modern Higher Algebra* (1859). French and Italian translations were widely circulated. In Germany it was Siegfried Aronhold who founded, in publications in 1858 and 1863, the symbolic notation which has been proved most effective for the explicit working out of invariants and their relations for particular forms and systems. It is, however, more to Clebsch, from 1861 on, that we owe the completion of this fundamental work. By its use Gordan (1868) proved the finiteness of the total system of covariants for any given binary forms, and so gave a climax to the earlier period of this new branch of algebra. Invention and discoveries have been less notable since that date, except for the climactic work of Hilbert, already described, and the systematizing publications of Study, Deruyts and the school of Sylvester. Important applications have been many, but the apparent tendency is to embody this theory as a typical and well developed part in the comprehensive theory of transformation-groups, of Sophus Lie. The most nearly complete history of this theory is Franz Meyer's *Bericht*.

ALGECIRAS or **ALGEZIRAS**, a seaport and railway terminus of southern Spain, in the province of Cadiz, 6m. W. of Gibraltar, on the opposite side of the Bay of Algeciras. Pop. (1920) 19,417. The name (Arabic, "island") is derived from a small islet on one side of the harbour. The fine winter climate attracts invalid visitors, on whom the town largely depends. Early in the 20th century it became a fishing-station, the Algeciras steam-trawlers visiting the Moroccan coast, as well as Spanish and neutral waters. Whale fisheries, with a floating factory and steam-whalers operating off Algeciras, were started by Spanish and Norwegian capital in 1923–25. Farm produce and building materials supply a fleet of small coasters with cargo.

Algeciras was perhaps the *Portus Albus* of the Romans, but was probably refounded by the Moors, who held it from 713 to 1344. It was then taken by Alphonso XI. of Castile after 20 months' siege which attracted crusaders from all parts of Europe; among them being the English earl of Derby, grandson of Edward III. It is said that during this siege gunpowder was first used by the Moors in the wars of Europe. The Moorish city was destroyed by Alphonso; it was first reoccupied by Spanish colonists from Gibraltar in 1704; and the modern town was erected in 1760 by King Charles III. During the siege of Gibraltar in 1780–82, Algeciras was the station of the Spanish fleet and floating batteries. The important international conference on Moroccan affairs, which resulted in an agreement between France and Germany, was held at Algeciras from Jan. 16 to April 7, 1906. (*See* MOROCCO.)

See O. Jürgens, *Die Spanische Städte* (Hamburg, 1926, bibl.).

ALGECIRAS CONFERENCE. On Aug. 8, 1904, a treaty was concluded in London by which France accorded absolute liberty of action to Great Britain in Egypt in return for a similar acknowledgment of French interests in Morocco. By a subsequent treaty (Oct. 1904) France concluded a secret arrangement with Spain. Disturbed by these agreements and determined to "vindicate" German rights in North Africa, the Emperor William II. landed at Tangier on March 31, 1905. Under his influence the sultan rejected the French scheme of reforms, and issued invitations to a conference of the powers. Serious friction between France and Germany followed, resulting in the fall of Delcassé, and the triumph for the moment of German policy.

The conference met at Algeciras on Jan. 16, 1906. Germany was backed by Austria, but the French claims were stoutly supported by Great Britain. A scheme of reforms was drawn up (*see* MOROCCO: *History*) and duly ratified; but Germany's principal object—to place France upon the same level as the other powers—was unsuccessful, and France was able to uphold her claim to a privileged position in Morocco.

ALGER, HORATIO (1834–1899), American writer, born in Revere, Mass., Jan. 13, 1834. He graduated at Harvard college in 1852, became a teacher and journalist, and in 1864 a Unitarian minister. He removed to New York city in 1866, and the experiences gained in his efforts to improve the condition of street boys there are reflected in many of his writings, which include over 100 books, mostly juvenile fiction of which many hundred thousand volumes have been sold. He died in Natick, Mass., 1899.

Besides contributing extensively to newspapers and periodicals, he published *Helen Ford* (1866) a novel; *Gran'ther Baldwin's Thanksgiving, With Other Ballads and Poems* (1879); the popular "Luck and Pluck," "Ragged Dick," and "Tattered Tom," series. *See* Herbert R. Mayes, *Alger, a Biography Without a Hero* (1928).

ALGER, RUSSELL ALEXANDER (1836–1907), American soldier and politician, was born in Lafayette township, Medina county, Ohio, on Feb. 27, 1836. He was admitted to the Bar in 1859 and began practice at Cleveland, Ohio, but early in 1860 removed to Michigan, where he engaged in the lumber business. Enlisting in a Michigan cavalry regiment in Sept. 1861, he rose from captain to colonel, distinguished himself in the Gettysburg

campaign, and under Sheridan in the Shenandoah valley, and in 1864 and 1865, respectively, received the brevets of brigadier-general and major-general of volunteers. After the war he invested in pine lands in Michigan and accumulated a large fortune. He served as governor of Michigan on the Republican ticket from 1885 to 1887. In 1889-90 he was commander-in-chief of the Grand Army of the Republic. From 1897 to 1899 he was secretary of war in President McKinley's cabinet. His administration of the war department during the Spanish-American War was severely criticized for extravagance, for unpreparedness, and for general inefficiency; charges which he answered in his *The Spanish-American War* (1901). The extent of his personal responsibility is uncertain. In 1902 he was appointed by the governor of Michigan, and in 1903 was elected by the State legislature, as United States senator to complete the unexpired term of James McMillan (1838-1902). He died at Washington, D.C., on Jan. 24, 1907.

ALGER, the central department of *Algeria* (*q.v.*).

ALGERIA, a country in North Africa under French dominion, bounded west by Morocco, north by the Mediterranean, east by Tunisia, and south by Italian Libya and French West Africa. North Algeria has an area of 207,915sq.km. between 37° and 34° N. lat. and 2° 10' and 8° 50' E. long.; it is 1,100km. long east to west, and 300-400 north to south, and so has the form of a narrow rectangle. The Saharan areas adjacent to Algeria have formed a separate administrative unit, the Southern Territories, since 1902; their area is 2,129,400sq.km., more than ten times that of North Algeria. The southernmost point in these Southern Territories, Tin Zaouaten, 20° N. lat., is 1,750km. from Algiers, while from the ocean to Tripolitania is about 1,800km. This immense area is, however, almost empty, and poor in resources at present utilisable, and it is a mere adjunct of the northern or true Algeria.

Physical Geography and Divisions.—The fundamental units, based mainly on climate, are the Tell, an area of trees and cultivation, the Steppe, with grasses and pastoral life, and the Sahara without water or trees save in oasis centres of irrigation. These are not continuous zones of constant breadth; there are wooded and cultivable patches in the Steppe and the Sahara, and arid patches in the Tell. Algeria is mainly highland, with mountain chains forming its borders and the steps of the main slopes. One must cross these mountainous borders to reach either the Mediterranean or the Sahara from the high interior, formed of mountain ridges and masses, and of plateaus or high plains with mild undulations. The highest points are Chéla (2,329 metres) in the Aurès and Lalla Khadidja (2,308 metres) in Kabylia, but the average elevation is about 900 metres and 68% of the area lies between 800 and 1,600 metres. Low plains cover only small areas near the coast in a few spots, but the coast generally is closely dominated by mountain lines, usually south-west-north-east. The slopes are usually very sharp, interrupted only by narrow breaches. The straight coastline has few shelters and deserves Sallust's designation of *littus importuosum*. A few semicircular gulfs, of Mers-el-kebir, Arzeu, Algiers, Bougie, Philippeville and Bône end westward against mountain-masses while eastward are shore deposits due to currents from the west.

Archæan and Palæozoic rocks occupy little space save near the coast east of Algiers where they are accompanied by volcanic extrusions. Secondary rocks, usually calcareous or marly, form the main skeleton of the Atlas chains from the sea to the Sahara. Tertiary rocks are also highly developed and include limestones, marls, sandstones, clays. Those of Oligocene or later date include fluviatile and lacustrine, as well as marine, deposits.

The Algerian chains show two series of foldings, the Tell Atlas and the Saharan or pre-Saharan Atlas, separated by a zone which narrows from west to east and is hardly folded at all.

In Algeria, west of the meridian of Algiers and Medea, the littoral massifs have a large tertiary depression on their south side; then comes the axial chain of the Tell Atlas with tertiary deposits to the south again. The Tlemsen-Saïda massif forms the third step and belongs climatically to the Tell but structurally to the main block. Beyond this to the south is the region of steppes with tertiary basins, of which the shotts fill the remnants. Finally, the Saharan Atlas forms a ridge fronting the desert. East of Al-

giers the zones are much less distinct. The Kabylia Tell is much higher and rougher than the Tell of Oran, and ends in the Edough massif at Bône, the end of the Tell Atlas. Beyond this, the Saharan Atlas with its north-eastward trend reaches the coast and separates the Algerian plateau from the Tunisian Sahel, with its tabular structure and its numerous small chains in the eastern part of the department of Constantine.

The North Sahara is built very simply. The Ahaggar, or central Tuareg massif, is made up of crystalline rocks surmounted

AN ANCIENT STREET IN ALGIERS, ALGERIA, WHICH ASCENDS BY COBBLED STEPS, PREVENTING ALL CONVEYANCES, EXCEPT SMALL BEASTS OF BURDEN, FROM PASSING THROUGH, AND WALLED ON EITHER SIDE BY PLAIN WHITEWASHED HOUSES OF MOORISH ORIGIN

by extinct volcanoes (Ilamane, 2,200 metres). Around it are the sandstone plateaus called the Tazili of the Azjer and the Muaydir-Ahmet. A great aureole of calcareous Cretaceous plateaus (Tademayt, El-Goléa, M'zab) separates the northward sloping Igharghar basin from that of the Saoura which slopes southward. The first has the oases of Warqla, Wad-Rir and the Zibans, the second those of Gurara, Tuat and Tidikelt. Vast dunes, the eastern and western Erg, complete the symmetry.

Climate and Hydrography.—In winter, westerly and southerly winds with rains come in from the west Mediterranean regions of low pressure. In summer the winds are from the east and north-east, and the air moves towards the superheated Sahara and is dry. The sirocco is a south wind that dries up the country. On the coast the winter temperature averages 50°-54°, the summer one 75°-79°, but the long duration of unvarying summer heat, accompanied by moist atmosphere, makes the summer very trying. Away from the sea continental conditions are very marked with strong radiation in a dry atmosphere. Average winter temperature here is 39°-43°, with much frost; summer temperature averages 79°-83° with average maxima near 95° or even 105° in the Sahara. Rainfall diminishes from January to August and increases from September to December. From June to September very little rain falls.

A zone from Dellys to the Tunisian frontier with coastal massifs gets more than 800mm. of rain (Bougie 1,036mm.). A zone along the coast from Tenes to Dellys and thence inland south of the previous one gets 600–800mm. (Algiers, 728mm.). The Oran coast west of Tenes and the remainder of the Tell get 400–600mm. (Constantine, 589mm.). The high plateaus and the pre-Saharan Atlas get 200–400mm., save on a few heights (Jelfa, 380mm.). The Saharan slope of the Atlas gets less than 200mm., that is small, irregular and accidental rainfall (Biskra, 143 mm.).

Most Algerian streams are periodic, with the rains, and many diminish from their sources downwards and may lose themselves in inland basins or in the Sahara. The Chelif is the chief river, over 700km. long, with an outflow varying from 30–15 cubic metres during the rains to a few hundred litres in the dry season. The lacustrine hollows, shotts or sebkhas, are occupied by salt deposits where evaporation has reduced them. On the Saharan slopes oasis irrigation and hot sands absorb the streams as soon as they leave the mountains. The Zousfana, helped by the Guir, occasionally reaches Fom-el-Kheneg. Wadi Mia and Wadi Igharghar are dead rivers; fossils in fact.

Flora and Fauna.—The flora includes 3,500 species of which 500 are peculiar. Evergreen trees and shrubs predominate and the olive is the characteristic tree. The barbary fig (*Opuntia Ficus indica*), the agave (*Agave americana*) and the widespread eucalyptus are imported types. On the highlands one finds either Central European or mountain Mediterranean plants. The woods include oaks (cork oak, evergreen oak, deciduous oak) and conifers (cedars, Aleppo pines, thuja, juniper). Regions with less than 350 mm. of rain are steppes with alfalfa (*Stipa tenacissima*), chih, (*Artemisia herba alba*), esparto grass and drinn. The limit of the steppe runs approximately through Sebdu, Saïda, Frenda, Tiaret, Boghari, Borj-Bu-Arrerij, Constantine and Suk-Ahras. The Saharan region has a poor xerophilous flora of peculiar species, some of which grow very rapidly after rain; the oases are characterized by the date palm, the sand dunes and ergs have a fair number of plants, the regions of clay and boulders (*Reg*). less and the regions of rock (*Hamada*) least of all.

There are few peculiar animals. The lion has recently become extinct here, the panther and hyena are still found in the woods and a monkey (*Pithecius imnuus*) occurs. Jackal and wild boar are very abundant and there are various antelopes (gazelles). The Saharan fauna is highly specialized; horned vipers and scorpions are fairly common.

Population.—In 1926 the population was 6,063,496, with a municipal population of 5,981,231. Of this total 542,225 live in the Southern Territories giving a density of less than one per sq. km. This figure rises to 26 in the north. The indigenous element is Berber with Arab admixture physically assimilated. Physically diverse types are seen everywhere and their origins are little known. Arab invasions have had little influence on racial types but have spread Islam and Arabic language; Berber dialects, however, survive in remote spots in Kabylia, Aurès and Saharan oases and among the Tuaregs. The Mozabites are not an orthodox Muslim people but belong to the Ibadite or Kharejite schism. Indigenous peoples number in all 5,147,872 including 532,091 in the Southern Territories, and they have increased rapidly under French rule, from less than 2,000,000 in 1830 and some 3,200,000 in 1886. The increase now reaches 400,000 in ten years or a doubling in 40 years. Three-quarters of the indigenous population live in the Tell and because of security and rain, mountain lands are more peopled than the plains (contrast Europe).

The urban element in this population comprises about 6%, much less therefore than in Tunisia or Morocco, and only 30 localities have more than 3,000 agglomerated natives in each. Outside the towns the greatest contrast is between sedentary cultivators living in houses aggregated into villages (thaddert) surrounded by gardens and planted woods, and nomad shepherds living in tents grouped into douars and moving about with their sheep and goats. There are also demi-nomads, living in gourbis more settled than the nomads, less fixed than the house-dwellers. A tendency exists to limit movements of nomads.

Europeans number 833,359, of whom 4,779 are in the Southern

Territories. Nearly all live on the coast and in the Tell, largely in towns, though there is an important rural element. The distribution contrasts with that of the natives for the department of Oran has 350,841, that of Alger 307,195 and that of Constantine 170,544. In the department of Oran Europeans occupy nearly all the cultivable land; in that of Alger they are numerous around Algiers, in the Sahel and in the Mitija; in that of Constantine they are sporadic.

From 1830 to 1856 the number of Europeans grew from 600 to 169,000 by immigration, but in that period deaths of Europeans were more numerous than births. Since 1856 births have been in excess, and there were 311,000 Europeans in 1876, 477,000 in 1891 and 752,000 in 1911. The increase is about 100,000 souls in ten years. Of the Europeans in 1926 there were 657,641 French, chiefly from southern departments (Corsica, Bouches-du-Rhône, Gard, Hérault, Pyrénées Orientales), and since 1896 more of the French have been Algerian born than French born. Spaniards from Murcia, Valencia, Alicante and the Balearics are numerous in the department of Oran. Italians from Sicily and Calabria occur especially in the department of Constantine. Maltese are to be found in most towns. Other Europeans are not numerous. Up to 1889 French and non-French European elements were about equal. To understand subsequent changes one must remember that many Frenchmen in Oran have married Spanish women, that any child born in Algeria is accounted as naturalized French unless he claims other nationality in the year of his majority, and that Jews, some of ancient settlement, others coming from Spain in the 16th and 17th centuries, were naturalized *en bloc* by the Crémieu decree (1870). An Algerian people is obviously forming itself and it is becoming purposeless, as well as almost impossible, to distinguish French born from naturalized citizens.

Towns.—Algiers, the capital has a total population of 226,218, with a municipal population of 214,920 (159,649 Europeans and 55,271 natives). Oran has a municipal population of 145,183 (120,568 Europeans), Constantine 88,582 (41,496 Europeans), Bône 48,570 (31,065 Europeans), Bel-Abbes 40,245 (28,024 Europeans), Philippeville 27,580 (19,288 Europeans), Mascara 27,231 (12,822 Europeans), Mostaganem 24,739 (12,539 Europeans), Tlemsen 24,511 (9,257 Europeans), Setif 22,916 (8,666 Europeans). The oases of the Sahara often have an urban character, e.g., Tugurt (12,108), Ghardaïa (10,689), El-Oued (8,621), Biskra (8,489), Laghwat (6,960).

Administration.—Algeria is neither a colony in the usual sense, nor a simple aggregate of French departments; it has not complete autonomy, yet it is not entirely assimilated to France. A governor-general of Algeria, appointed by the minister of the interior, is helped by a general secretary and a council. Algeria is represented in the French parliament by three deputies for each of its three departments and by senators. It also has two local assemblies. The financial delegations are an assembly on which colonials elect 24, non-colonials 24, and Muslim natives 21 members, with a special Kabyle section in the last group. The *Conseil supérieur* is made up of elected and official elements. These two assemblies vote the local budget instituted by law in 1900 to permit Algeria to raise revenue in the usual ways, including excise and monopolies, and leaving Algeria responsible for its debts, administration, public works and so on, subject to control and veto of the French Government. France pays the military and naval expenses but Algeria paid a war contribution of 6% of its budget. That budget is now about 1,000 million francs, and has usually shown a surplus. Fiscal schemes are based on those of France, and taxes are the same for Europeans and natives.

Northern Algeria has three departments (Oran, Algér, Constantine), divided into arrondissements which include *communes de plein exercice* with administration on French lines, and *communes mixtes* with natives in large numbers. The latter divisions are often large and are under special administrators, each has a municipal council helped by native sheikhs, caïds or aghas. Natives elect representatives on all local assemblies.

The Southern Territories, with a separate budget, were created by decree of Dec. 24, 1902; they are named Ain-Sefra (capital same name), Ghardaïa (capital Laghwat), Tugurt (capital same

name) and the Oases (capital Warqla). At the head of each is a military commandant acting under the governor-general, and each is divided into circles, annexes, "communes mixtes" and native communes. Old Arab taxes have been continued and order is guarded by méharist camel corps, forming the Saharan companies.

Algiers has a university with faculties of law, medicine, science and letters which have produced much research in science, history, archaeology, linguistics, law and medicine, especially relative to North Africa. Primary and secondary schools for Europeans are on French lines. Most natives do not go beyond the primary school but there are higher schools, called Medersas, for Muslim functionaries. The knowledge and use of French has spread very widely among the natives.

Landed Property.—The absence of large empty areas and the rapid occupation of reserves have created problems. Land was distinguished as *melk*, private property often unenclosed, save in Kabylia, and *arch*, tribal land owned by the sovereign for the use of the tribe. In 1863 the tribes were declared proprietors of the lands they had been using, and their delimitation and their division between the various douars was ordered with a view to division among individual members of these lesser groups. The last step was not taken and a Warnier law (1873) renewed the effort, but defective administration made another law necessary in 1897, and still another one (Aug. 4, 1926) now controls this task which it is so difficult to carry through without revolutionizing native society. Public and private state domains amount to 5,114,000 hectares, communal lands and zones of transit 4,153,000 hectares, European private property 2,400,000 hectares, enfranchised private property of natives 1,813,000 hectares, *melk* lands 4,647,000 hectares, *arch* lands 2,767,000 hectares.

Free grants of land, with obligatory residence, have been the rule save under the Second Empire. Four modes of transfer are recognized by the decree of Sept. 13, 1904, namely, sale at a fixed price at public office, the usual method, sale by auction under public control, sale by private treaty and free concession. A decree of Sept. 9, 1924, has lengthened the period of obligatory residence from ten to 20 years, and the period during which the lands may be transferred only to French colonists from 20 to 40 years. The proportion of colonization land reserved to Algerians has been increased from one-third to one-half. Of 2,400,000 hectares of colonization land 700,000 have passed into European hands by private purchase, the remainder being occupied by official colonization. There are 600 European agricultural centres, 230,000 agriculturists, 90,000 proprietors. Official colonization has nearly come to an end, and can do little more than develop communications and build new hamlets at spots reached by them.

Agriculture.—Cereals are the chief crop occupying 3,000,000 hectares; native methods are very primitive, but Europeans, by preparatory work and by scientific dry farming, have much increased the yields, which, however, vary greatly with the rainfall. The yields of soft wheat are two million quintals from Europeans and 600,000 from natives, of hard wheat two million quintals from Europeans and four from natives, of barley one and a half million quintals from Europeans and six and a half from natives. Oats, maize and sorghum (*bechna*) are less important. The vine has been the chief plant cultivated by Europeans since the *phylloxera* ruined the vineyards of South France and made the vine growers go to Algeria. Vines occupy 201,000 hectares (Oran 108,000, Alger 77,000, Constantine 16,000). There are vineyards of the plains, of the hillsides and of the mountains and yields of wine vary greatly. *Phylloxera* has ravaged the Algerian vineyards which were reconstituted with American plants. Eight to ten million hectolitres of wine are produced on the average each year and the great market for this product is France. The olive is widespread and its products are used by the natives. Of six million grafted olive trees, three million are in Kabylia and four million belong to natives. The average production is 300,000 quintals of oil. Figs, oranges, apricots and almonds are also grown. The cultivation of early products owes much to the mildness of winter along the coast, and peas, beans, artichokes, tomatoes, potatoes and grapes are grown near the export harbours. Tobacco crops cover

32,000 hectares and produce 300,000 quintals of leaves, Kabylia being the chief centre of this recent development. About half the tobacco belongs to natives; part is exported, part manufactured locally. Plants for perfumery are grown near Algiers. Experiments in cotton growing were made during the American Civil War (9,000 quintals ginned cotton) and renewed since 1906 in the Cheliff valley. In 1926 this crop covered 6,700 hectares (Oran 4,000) and produced 47,000 quintals gross, yielding 13,000 quintals of ginned cotton. There are about 1,000 irrigation schemes, watering more than 200,000 hectares and using both barrage source lakes and barrage collecting reservoirs. More are being built, especially in the Cheliff valley. In the Southern Territories there are about four and a half million date palms (900,000 in Wad Rir) and the digging of artesian wells is extending areas of cultivation and revivifying old oases that had decayed.

Stockraising is important with eight to nine million sheep, four million goats, one million cattle, 200,000 horses, 300,000 asses, 150,000 mules and 150,000 camels, the camel being used as a pack animal on the steppes and more especially for riding in the Sahara. The sheep suffer from drought, cold and parasitic diseases; about one million are exported every year, chiefly for meat. Wool production is small, less than 18,000 tons.

Forests occupy three million hectares, but much of this is mere scrub. Fires and trespass of flocks are the great enemies of the forests. 200,000 quintals of cork are produced. Alfa covers four million hectares and gives 1,500,000 quintals for paper-pulp. The dwarf-palm yields 500,000 quintals of fibre.

Minerals.—Algeria (Jebel-Kuif near Tebessa) with the even richer Morocco and Tunisia together lead the world for production of phosphates of lime, yielding more even than U.S.A. Algeria's share is 800,000 tons. Iron ores (1,600,000 tons) are of good quality and are found near the Tunisian frontier (Wenza, Bu-Kadra), in the Miliana region (Zaccar, Ruina) and on the Oran coast (Beni-Saf); they are mostly sent to England. Zinc (40–50 thousand tons) and lead are found in several places. Constantine is the richest of the departments in mineral products. Prospecting for mineral oil at Ain-Zeft (Dahra) and at Messila (south of Relizane) has yielded poor results and there is but an insignificant coalfield at Kenadsa in the south of Oran. Algeria therefore exports its minerals in the crude state, but their extraction has caused railway developments, the growth of centres of population in districts previously empty, and traffic at the ports.

Industries.—Native industry cannot compete with European, but efforts have been made to keep up the traditional carpet-weaving. European industries include those dependent on crops e.g., oil mills, distilleries and flour mills, also the making of leather, tobacco and matches, and some salting establishments. None is very highly equipped.

Communications.—4,345km. of railway, partly 1.44m., partly 1.05m. gauge, are in use and are worked partly by the P.L.M. railway of France and partly by the railway company of Algerian State railways. A central line goes from the Moroccan to the Tunisian frontier and has branches to the ports of Beni-Saf, Oran, Arzeu, Mostaganem, Tenès, Algiers, Dellys, Bougie, Philippeville, and Bône, as well as southward to Ras-el-Ma, Colomb-Béchar, Kenadsa (770km. from Oran), Tiaret, Jelfa, Aumale, Tugurt (543km. from Philippeville), Khenchela and Tebessa. An excellent network of roads supplements the railway. A trans-Saharan railway has been proposed, and automobiles now work in the Sahara.

The ports of Algiers (2,642,000 tons cargo and 2,560,000 tons shipping), Oran (2,215,000 tons cargo and 3,308,000 tons shipping), Bône (1,272,000 tons), Philippeville (294,000 tons) and Bougie (250,000 tons) are fully equipped. Secondary ports include Nemours, Beni-Saf, Mostaganem, Cherrhell, Jijelli, Collo, and La Calle. By a law of 1889 only French ships may trade between France and Algeria.

Commerce.—Since 1867 there is complete reciprocity between France and Algeria in customs dues, and trade consists of the sale of Algerian agricultural products and the importation of manufactured goods, metals, coal and produce of other colonies. Wine, oil, cereals, sheep, wool, iron ore and phosphates are ex-

HISTORY

The history of Algeria, which constitutes the central part of Barbary or Moghreb, has almost always been bound up with that of Morocco and Tunisia, which are respectively the western and the eastern parts of that great natural region. The actual name of Algeria, or rather of the regency of Algiers, does not appear until the 16th century, when Turkish rule was established in the central Moghreb.

Northern Africa has from the most ancient times been a meeting-ground for races of different origin. According to anthropologists the native populations of Algeria, taken as a whole, belong to a Hamitic strain which is stated to have occupied the whole of North Africa, including both the eastern and the western portions, to have been represented by considerable groups in the heart of the African continent, and also to have contributed to the population of southern Europe. These peoples are generally known as Berbers; they are not, however, homogeneous, but differ considerably from one another both in bodily characteristics and facial type. The Berber dialects, which belong to the so-called Hamitic or proto-Semitic group, are still spoken in Algeria by approximately one-quarter of the native population.

Algeria During Antiquity.—The history of Algeria is the history of successive conquests: the Carthaginian, the Roman, the Vandal, the Byzantine, the Arab, the Turkish and the French. As there was no one natural centre for the whole country, political divisions were constantly changing. The Berber tribes never succeeded in combining to form a properly organized and durable State; they only ceased their internecine strife to be swallowed up in some vast empire whose centre was elsewhere than in North Africa: sometimes in Spain, sometimes in the East. The successive empires sprang up suddenly and disappeared with equal rapidity. The history of Algeria has no unity; it is not the story of a nation or of a historical community. The Berber tribes were split up like the land which they inhabited; each small settlement and each tribe had a history of its own.

The Phœnician colonization marks the beginning of the historical age in North Africa. As early as the 12th century B.C. the Phœnicians founded settlements on the African coast. In the 8th century Carthage supplanted the earlier metropolis and imposed its suzerainty on the Phœnicians of the East. During the seven centuries for which it endured, the Punic civilization penetrated more or less deeply into the Berber districts, and the Punic tongue long continued to be spoken.

After the fall of Carthage (146 B.C.) Rome governed the country through native kings. The Roman occupation was at first limited and only extended itself little by little. Complete

annexation only took place under Caligula (A.D. 40). Algeria constituted the provinces of Numidia and Mauretania Caesarea. Even at its height, Roman domination did not extend over the whole of present-day Algeria; the frontier passed south of the Aures, but then turned north, leaving out the steppe zone of the provinces of Algiers and Oran.

Roman colonization of the country was effected by three methods: introduction of colonists, intermarriage between Romans and natives and the transformation of natives into Romans. Probably it was the last method which everywhere gained the upper hand. By the middle of the 2nd century A.D., Latinized Africans were to be found throughout the empire. The most famous authors produced by Latin Africa were Apuleius of Madaura among the pagans and St. Augustine of Thagasta among the Christians. Numerous and wealthy cities sprang up and roads were constructed. It was a period of great material prosperity, based mainly on agriculture. The wealthiest province was Constantina, which was much more completely Romanized than the rest of Algeria. The main crops cultivated were wheat and olives.

For two centuries (A.D. 40–238) Roman Africa enjoyed a period of complete peace, until this was destroyed by religious disturbances, native revolts, and finally the Vandal invasion, which was followed by a brief restoration of Byzantine rule.

The Middle Ages: Arabs and Berbers.—In the 12th century, what remained of Roman civilization in North Africa was finally destroyed by the Arab invasion. Algeria was thus detached from the Latin world and absorbed into that of Islam. The first Arab invasion, which took place in the 7th century, was the beginning of an era of anarchy and incessant warfare. The Berbers resisted at first and then embraced a heretical form of Mohammedanism known as Kharedjism. They were swept by the Mohammedans into the wars for the conquest of Spain and subsequently of Egypt. The second Arab invasion of North Africa, which was carried out in the 11th century by the Hilal and Soleim tribes from the Hedjaz, completed the ruin of the country. The ethnographical character of the population was not, however, so profoundly affected by the invasion as was at one time believed. The invaders almost everywhere became amalgamated with the native population; the latter were, however, uprooted and thrown into confusion, and many of them took refuge in the mountainous districts or in the Sahara. In the towns and in the plains the Arabs gradually imposed their language and religion.

The Berbers nevertheless set up large and powerful empires during the middle ages. Two dynasties of a religious and reforming character were founded, that of the Almoravids and that of the Almohads, the former by the nomads of the Sahara and the latter by the Berbers of the Moroccan Atlas. Their rule extended not only to the whole of North Africa but also to Spain, and the civilizing influence of the latter country made itself felt upon them.

Three kingdoms were founded in the 13th century on the ruins of the Almohad empire: that of the Merinids of Fez, that of the Abd-el-Ouadites of Tlemsen, and that of the Hafsiides of Tunis. The three kingdoms corresponded approximately to the modern Morocco, Algeria and Tunis; but their Mohammedan sovereigns never succeeded in establishing their authority firmly over the territories in which their suzerainty was more or less recognized. Their history consists in incessant struggles between dynasties, chronic insurrections and disturbances, raids and the sacking of towns. By the beginning of the 16th century the Berber communities were hopelessly disintegrated and incapable of joint action; anarchy had reached its high-water mark and the ruin of the country was complete. From that time onwards North Africa was contested for by the two dominant foreign influences in the Mediterranean: that of the Spaniards and Portuguese and that of the Ottoman Turks.

The Turkish Period (1518–1830).—Once they had reconquered the Iberian peninsula the Spaniards and Portuguese continued the struggle against the Mohammedans in North Africa. Cardinal Ximenes regarded the conquest of Algeria as necessary for the expansion of Spain. Oran was captured in 1509 and Algiers in 1510; on a small island in the harbour of Algiers the victors built a fortress, the Peñon, the guns of which could sweep the

town from a distance of 300yd. Spain was soon mistress of a large part of the coast of Algeria.

The Spanish successes were not, however, lasting. The natives, wishing to be delivered from the Spaniards, called in two Greco-Turkish corsairs, the brothers Barbarossa. The first, Aroudj, captured Algiers and Tenes, and destroyed the dynasty of the Abd-el-Ouadites of Tlemsen. His brother, Kheir-ed-Din, succeeded him, and was the real founder of the regency of Algiers. He did homage for the conquered country to the sultan of Constantinople, who conferred on him the title of Beylierbey (Bey of Beys), and authorized Turks to serve under his banner. In 1529 Kheir-ed-Din captured the Peñon and built a mole to connect it with the mainland, thus forming the famous harbour which until 1830 was the impregnable stronghold of the corsairs. Charles V. attacked Algiers in 1541 but failed lamentably. The Spaniards only retained Oran, which was taken by the Turks in 1708, recaptured by the Spaniards in 1732, and finally abandoned by them in 1791.

The first period of the Turkish rule in North Africa (1518-87) ended with the reign of Euldj-Ali, the last and the most notable of the African Beylierbeys. It was followed by the period of the triennial pashas (1587-1659), and then by that of the deys (1659-1830). The three phases imply something more than a mere change of title of the rulers of the regency; they represent an increase in the independence of Algeria from Constantinople, and also a growing anarchy. The real rulers of the regency were the *odjak*, or militia, and the *taiife* of the *rais*, or corporation of corsairs. The militia was a military corps recruited in Asia Minor which governed itself on the most democratic lines; its members, the janissaries (*q.v.*), all received equal pay and were promoted by seniority only. The *rais* or corsair captains were mostly of Christian origin. The internal history of Algeria at this period consists entirely in the unending strife between these two rival powers, the *odjak* and the *rais*. The Turks governed the native tribes by setting them one against the other. They gained the support of certain tribes known as the *makhzen* tribes, which were liable for military service but not for taxation. The remaining tribes, known as the *raias*, bore the whole burden of taxation. The Turks did not interfere with the manners and customs of the natives, but only required them to pay taxes and allow them free passage through their territory. In theory the tribes were governed either by the Beylik of Medea or Titteri, that of Constantine, or that of Mascara, the capital of the last being later transferred to Oran. Most of them, however, were never really reduced to subjection.

For 300 years Algiers was the headquarters of piracy, the meeting-place of sea-robbers, and the terror of all civilized countries, which it defied with audacity born of long impunity. The punitive expeditions of the European Powers against the Algerians were generally undertaken haphazard and after insufficient preparation. Bombardments and blockades produced no lasting result. The principal expeditions were those of Duquesne (1683), Marshal d'Estrées (1688), O'Reilly (1774) and Lord Exmouth (1816).

ALGERIA UNDER THE FRENCH

The settlement of the French in Algiers opened a new period in the history of North Africa. In the 16th century traders from Marseille set up coral fisheries on the Barbary coast, at Bône, at Calle and at the Bastion de France. France had maintained more continuous relations with the regency than any other Christian nation. A dispute arose with the dey in connection with the wheat supplied to the directoire by two Jews of Algiers, Bakri and Busnach. In the course of the negotiations which were undertaken to settle the question, the dey Hussein struck Deval, the French consul, with a fly-whisk (April 1827). The dispute became so bitter that after a blockade lasting three years it was decided to send an expedition. The command of the army was entrusted to Gen. de Bourmont, and that of the fleet to Admiral Duperré. A French force of 37,000 men landed at Sidi-Ferruch on June 14, 1830, and Algiers capitulated on July 5.

The French found, however, that although they had put an end to Turkish rule in Algeria, they were not yet in possession of the

country. It had to be wrested yard by yard from the native population. This task was not undertaken without much hesitation. The July monarchy wavered for some years between the idea of conquering the country completely, occupying a part of it and evacuating it altogether. A section both of parliament and the press urged that Algiers should be given up. It was not until July 22, 1834 that a decree was issued appointing a governor-general of French possessions in North Africa. From 1834 to 1840 an attempt was made to confine the occupation to a few points on the sea-board, Algiers, Oran, Bougie and Bône, with the districts immediately surrounding them. There were frequent changes in the command of the army, and governors succeeded one another rapidly. In the course of ten years the successive governors were Bourmont, Clauzel, Berthezène, Rovigo, Voirol, Drouet d'Erlon, Clauzel again, Damrémont and Valée. The ablest of these early governors was Clauzel, but he had neither the time nor the troops necessary to carry out his plans.

The resistance of the natives in the province of Constantine centred round the bey Ahmed, and in the rest of Algeria round Abd-el-Kader. An expedition against Constantine, undertaken in 1836, was a failure, and success was not achieved until the next year. In 1838 Marshal Valée organized the province of Constantine. The administration was entrusted to important native chiefs who were subject to the authority of the commandant of the province.

Abd-el-Kader was a marabout of the district of Mascara, who in his early days was of little importance. The French at first tried to work with him, but the treaty signed by Gen. Desmichels (1834) and the treaty of Tafna (1837) greatly increased his prestige among the natives. Abd-el-Kader, who possessed real military and diplomatic gifts, was the most formidable adversary whom the French ever encountered in Algeria. He attempted to create an administration, a regular army, and a system of taxation. His final downfall was largely due to the natives themselves, who refused to sink their private quarrels and accept his leadership. In 1839 Abd-el-Kader, maintaining that the expedition which had linked up Constantine with Algiers was a violation of the treaty of Tafna, proclaimed a holy war and ravaged the prosperous settlements which the French colonists had established in the Mitidja.

The Government then decided to prosecute the war in Africa with vigour, and sent out Bugeaud (1841-47). His arrival put an end to the long period of vacillation and uncertainty. Bugeaud was a man of energy and persistence and a first-class soldier. He was the real creator of the African army. He abandoned the system of small forces in block-houses, where they were decimated by sickness and by the boredom of inactivity. Instead, he sent out flying columns in all directions, burdened with the least possible baggage so that they could strike quickly and attack the material interests of the enemy by carrying off his cattle and his crops. The war against Abd-el-Kader was long and wearisome. The principal events were the capture of Takdempt, Abd-el-Kader's stronghold (1841), the taking of Smala by the duc d'Aumale (1842), Bugeaud's victory at Isly over a Moroccan army (1844) while the prince de Joinville was bombarding Tan-giers and Mogador and finally the surrender of Abd-el-Kader to Lamoricière (1847).

Bugeaud also set up the department for native affairs and Arab bureaux, which was established by the ministerial order of Feb. 1, 1844. The department, which was now staffed with officers well acquainted with the language, institutions and customs of the population, had to administer the country and supervise the native chiefs. Bugeaud regarded colonization as a necessary auxiliary to conquest. His aim was to transform Algeria into a French territory by rural colonization. He permanently settled 40,000 French colonists in Algeria. Bugeaud's colleagues were Lamoricière, Bedeau, Changarnier and the duc d'Aumale for military affairs, Daumas, Léon Roches, Lamoricière and Cavaignac for native affairs, and Guyot for colonization. He had what his predecessors had lacked: time, full powers and an army of 100,000 men. By 1848 the conquest of Algeria could be regarded as accomplished.

Algeria is so near to France that it has always quickly reflected events occurring either in the domestic or foreign affairs of that

country. Thus the revolution of 1848 led to important changes in the organization of Algeria. It was declared a French territory, and was divided into departments similar to those of France, each administered by a prefect. New colonists, largely recruited from the unemployed of Paris, were sent out. Algeria was included in the French customs system by the Act of Jan. 11, 1851.

After the *coup d'état* Gen. Randon (1851-57) was appointed governor-general. He completed the conquest of Algeria by the subjection of Kabylia of the Djurjura (1857), which was the only part of the Algerian Tell not yet under French influence. Here he constructed the Fort-Napoléon (Fort-National) as a "thorn in the flesh" of the country. The policy of colonization was continued, and the first railways constructed.

In 1858 the governor-generalship was abolished and replaced by a ministry of Algeria and the colonies. This office, however, only had a brief existence; it was held by Prince Jérôme Napoléon and the comte de Chasseloup-Laubat. The governor-generalship was re-established by the order of Nov. 24, 1860. The new governor-general was Marshal Pélissier (1860-64) who was succeeded on his death by Marshal de MacMahon (1864-70). The emperor Napoleon III. had views of his own about Algeria, which he explained in two open letters in 1863 and 1865. He said that Algeria was an Arab kingdom, and he did not encourage colonization. In place of Bugeaud's policy of populating the country, he adopted the policy of economic development by great financial companies. These views were embodied in the senatorial decree of April 22, 1863, which gave the tribes ownership of the lands which they held by no matter what right, and in the senatorial decree of July 14, 1865, which declared the natives French subjects and gave them facilities for acquiring rights of citizenship. Napoleon III.'s innovations were on the whole unpopular. State property in Algeria suffered, and colonization was hampered and discouraged.

The revolt of the Ouled-Sidi-Cheik (1861-83) in the south Oran district did not affect the rest of Algeria. Its long duration is to be explained by the fact that the adjoining country, Morocco, was in a state of anarchy, and the insurgents were thus able to find in it both a refuge and support. As a result of the famine from which the native population suffered in 1868 and the agricultural enquiry carried out by the comte le Hon, a draft constitution was drawn up by Armand Béhic, according to which Algeria would have obtained a considerable measure of autonomy.

The revolution of Sept. 4, 1870 was followed in Algeria by a period of agitation and disturbance which produced the most deplorable effect upon the native population. A series of orders were promulgated which aimed at the complete assimilation of Algeria to France, in accordance with the demands put forward by the colonists on the fall of the empire. One of the decrees naturalized the Algerian Jews *en bloc*. The native insurrection which broke out in March 1871 and lasted until Jan. 1872 was not a rising of oppressed peoples against the oppressor, or a national struggle for freedom, since no nation existed; still less was it a religious war. It was simply the result of the defeats which France had suffered in Europe and of the anarchy which ensued. The leaders were the great native chiefs who felt their interests and privileges to be in danger, particularly Mokrani, bach-aga of Medjana. It raged most severely in the province of Constantine and Kabylia. The revolt was put down with severity; the insurgent tribes had to pay a heavy indemnity, and their lands were sequestered.

The governor-generalship, which had been abolished in 1870, was re-established in 1871. Algeria now had a civilian governor-general coming under the ministry of the interior instead of the ministry of war. The post was entrusted to Admiral de Gueydon, a broad-minded and energetic man and an excellent administrator. He was a strong partisan of colonization, which was energetically resumed. The Native Property Act of 1873 was intended to facilitate the acquisition of Mohammedan lands by Europeans. The colonization policy was pursued under the governorship of Gen. Chanzy (1873-79). In 1881 the European population reached the figure of 376,000, of whom 140,000 were settled on the land.

From 1881 to 1896 the policy of complete assimilation of Algeria to France once more prevailed. The civil lands were greatly extended so as to cover the whole of the Tell and a large

part of the higher plateaux. The districts which were almost entirely inhabited by natives were given the name of mixed communes, and civilian administrators were appointed to deal with them instead of the officers of the Arab bureaux. Finally, by the *décrets de rattachement* of Aug. 26, 1881, Algerian affairs were allotted to the various ministries of France itself, so that the position of the governor was reduced merely to that of an agent for the transmission of instructions. The disadvantages of this system were not long in making themselves felt; attention was drawn to them in the able reports of Burdeau in 1892 and Jonnart in 1893, and in the speeches of the governor-general, Jules Cambon (1891-97). The senate appointed a committee known as the *Commission des XVIII.*, which sat from 1892 until 1896 under the chairmanship of Jules Ferry, in order to study the changes which should be introduced in the legislation and organization of Algeria. It declared definitely against the system of attachment to French ministries.

An order issued on Dec. 31, 1896 revoked the orders of 1881 and restored the governor-general's powers so that he once more became the head of the administration of Algeria. The decentralization was completed by the orders of Aug. 23, 1898, which established the system still in force. The powers of the governor were defined, the Superior Council was reorganized, and in addition to that body, which was composed of officials and elected members, there was set up a new assembly, nearly all of whose members were elected. This body, which is known as the Algerian financial delegations, has three sections providing separate representation for colonists, non-colonists and natives. The Act of Dec. 19, 1900 entrusted the two bodies mentioned above with the right of voting the budget, subject to the supervision of the home government and of parliament. A separate budget for Algeria was instituted, the expenditure being divided into obligatory and optional expenditure. Civil personality was conferred on the colony, and it was empowered to contract loans. The intention of these measures was to give the Algerians the opportunity of managing their own affairs. By the Act of Dec. 24, 1902 the southern territories were transformed into an administrative unit distinct from north Algeria, and were also granted civil personality and a separate budget. This measure was necessitated by the fact that since 1900 the territory of Algeria had been considerably extended towards the south, owing to the occupation of the oases of Touat, the pacification of the central Sahara and the joining up of North Africa and the Sudan.

The system set up in 1898-1900 has, generally speaking, worked well. The policy followed has been, while maintaining the right of suzerainty of the home country, to provide the colony with a suitable administrative system not by automatically transferring to it the legislation and institutions of France but by adapting them in a careful and practical way. The governors-general of Algeria since 1898 have been either civil servants or members of parliament on mission. Their names are as follows: Laferrière (1898), Jonnart (1900), Révoil (1901), Jonnart again (1903), Lutaud (1911), Jonnart for a third time (1918), Abel (1919), Steeg (1921), Violette (1925) and Bordes (1927). Many of the governors-general have been able statesmen; but it is regrettable that their terms of office should have been so short.

The policy adopted towards the native population has throughout the 20th century constantly progressed in the direction of greater liberality. Native conscription was instituted by the order of Feb. 3, 1912; this accelerated the movement and led to the almost complete abolition of the system under which certain acts constituted offences in the case of natives only, and natives were tried by special courts. During the World War of 1914-18 the Algerian natives showed the utmost loyalty in spite of all foreign incitement to rebel. They furnished 173,000 fighting men and 119,000 workers and the losses in killed and missing amounted to 25,000 soldiers. The Arab taxes were abolished by the order of Nov. 30, 1918; all inequalities and privileges in the matter of taxation have now disappeared. Under the Act of Feb. 4, 1919, concerning the admission of natives to political rights which was drafted by Governor-General Jonnart, they are represented in all the deliberative assemblies of Algeria by elected members possess-

ing the same rights as the French members. The electorate has also been considerably extended.

The policy of populating the country with French colonists has been pursued as far as circumstances permitted. A new nation is being created in Algeria by fusion between the French elements and the various foreign elements, mainly Spanish, who were more or less automatically naturalized by the Act of June 26, 1889. Two thousand lives were lost and £5,000,000 worth of damage done in floods in western Algeria in Nov. 1927. In 1928 there were further floods. In that year preparations were begun for celebrating in 1930 the centenary of the French occupation.

ALGHERO, seaport and episcopal see, province of Sassari, West Sardinia, 21m. S.W. by rail from Sassari. Pop. (1921) 12,280. The cathedral is 12th century; the see dates from 1503. Founded by the Doria family of Genoa about 1102, it was occupied by the house of Aragon in 1354, who held it until it fell to the house of Savoy with the rest of Sardinia in 1720. Catalanian is still spoken here. The district produces good wine. Seven miles N.W. is the fine natural harbour of Porto Conte, secure in all weather, and on the west of this harbour is the Capo Caccia, with two stalactite grottoes. The important prehistoric necropolis of Anghelu Ruju is 6½m. N. of Alghero.

ALGIDUS MONS, the east part of the ridge of the larger crater of the Alban volcano (see **ALBANUS MONS**), traversed by a narrow opening (now called the Cava d'Aglio) used for the Via Latina. There was a temple to Diana, the site of which is unknown.

ALGIERS, capital of Algeria, the seat of the governor-general, and of the Algerian assemblies, of a court of appeal, of the XIX Army Corps and of an archbishop. It is built on the west side of the bay of Algiers, 36° 47' N., 3° 4' E., on the slopes of the Sahel hills parallel to the coast and backing on to Mt. Buzareah. The growth of the town has been conditioned by the scarps which approach the coast very closely and by military necessities. Turkish Algiers was triangular, with the Casbah as its apex and a line of rocky sea-cliffs, now the boulevard de la République, as the base. The two other sides are marked by great flights of steps built in the ditches of the Turkish ramparts and leading up, the one to the mosque of Sidi-Abderrahman, the other behind the theatre. French Algiers has grown piece-meal. Buildings now stretch almost without a break for 16km. from north to south.

Modern Algiers is a large city of European type with regular, often arcaded, streets. Many mosques, Janissary-barracks and several fine Moorish houses have gone. The border of the harbour is formed by the boulevard de la République, continued north by the boulevard de France and south by the boulevard Carnot. The arches supporting the boulevards stand 15 metres above the quays. The chief official and commercial buildings of Algiers are on these boulevards. The north end of the boulevard de la République, la place du Gouvernement, was long the centre of the town with the roads Bab-el-Oued, Bab-Azoun and la Marine starting from it. The suburb of Bab-el-Wad is peopled mainly by Spaniards and farther north is the suburb of S. Eugène dominated by the basilica of Notre Dame d'Afrique. West of the place du Gouvernement a short street leads to the modern cathedral (1845-60) on the site of a mosque, the governor's winter palace, and the old palace of the archbishops, the remains of the Jénina or palace of the Dey. Near by is the National Library, in one of the finest Moorish houses of Algiers (1798). The area between the sea, the rue de la Marine and the rue Bab-el-Oued is the Algiers of the conquest and is full of old houses on narrow streets. The busy rue Bab-Azoun leads to the square de la République whence start the rue d'Isly and the rue Dumont-d'Urville, the busiest of Algiers' centres of commerce.

The highest part of Algiers, on steeply scarped hills, has preserved best its native character, but it has been disfigured by the cutting of the rue Randon and rue Marengo.

The Casbah fortress, 118 metres above sea-level, belongs to the 16th century and was the residence of the two last Deys, who left Jénina for it. Here Dey Hussein struck the French consul with a fly whisk on April 30, 1827, whence followed the capture of Algiers and the end of Turkish rule.

Mustapha, once a suburb, then a separate commune, but now reunited to Algiers, has grown very much since the fortifications between it and Algiers were demolished, and the two are now continuous. The lower streets are populous and industrial, the upper ones have villas with fine sea-views. Here also are the Governor's summer palace, the university, and the museums.

Kheir-ed-Din created the old Turkish port of Algiers by building a jetty to join the Peñon islet to the mainland. This islet retains the lighthouse, the admiralty building, various buildings of the Turkish period and some of the period of Spanish dominance, and extends north and east of the shallow pool where fishing boats, pleasure boats and torpedo boats are moored. To the south of this pool lies the immense stretch of water of the modern port.

Algiers ranks next after Marseille among French ports for tonnage cleared, thanks to vessels calling for coal, and next after Marseille and le Havre for number of ships. In 1926, 1,261,796 tons of merchandise (44% of Algeria's total) were landed and 1,380,056 tons (29% of Algeria's total) exported. Tonnage cleared totalled 2,562,241 tons. Algiers imports coal, cotton goods, metal objects, waggons and automobiles, and exports wine, sheep, skins, fresh vegetables, grapes, potatoes and iron ores. The regular service to Marseille involves a voyage of 497 knots or at present 26 hours, and Algiers is thus 40 hours from Paris.

The importance of Algiers is steadily increasing both from the political and business point of view, and as a place of residence.

The total population (1926) is 226,218, with a municipal population of 214,920 (French 134,628; other Europeans 25,021; natives 55,271). With the suburbs which are continuous with Algiers (Buzareah, 2,619; El Biar, 6,988; Hussein Dey, 10,276; S. Eugène, 7,044; Maison Carrée, 14,648), the city has 256,495 inhabitants (187,416 Europeans and 69,079 natives).

History.—In Roman times a small town called Icosium existed where is now the marine quarter of the city. Roman cemeteries existed near the present streets of Bab-el-Oued and Bab-Azoun. Bishops of Icosium are mentioned as late as the 5th century. The present city was founded in 944 by Bulukkin b. Zeiri, the

founder of the Zeirid-Sanhaja dynasty, which was overthrown by Roger II. of Sicily in 1148. (See FATIMITES.) The Zeirids had before that date lost Algiers, which in 1159 was occupied by the Almohades, and in the 13th century came under the dominion of the Abd-el-Wahid, sultans of Tlemçen. Nominally part of the sultanate of Tlemçen, Algiers had a large measure of independence under amirs of its own, Oran being the chief seaport of the Abd-el-Wahid. The islet in front of the harbour, subsequently known as the Peñon, had been occupied by the Spaniards as early as 1302. Thereafter a considerable trade grew up between Algiers and Spain. Algiers, however, continued of comparatively little importance until after the expulsion from Spain of the Moors, many of whom sought an asylum in the city. In 1510, following their occupation of Oran and other towns on the coast of Africa, the Spaniards fortified the Peñon. In 1516 the amir of Algiers, Selim b. Teumi, invited the brothers Arouj and Khair-ed-Din (Barbarossa) to expel the Spaniards. Arouj came to Algiers, caused Selim to be assassinated, and seized the town. Khair-ed-Din, succeeding Arouj, drove the Spaniards from the Peñon (1530) and was the founder of the pashalik, afterwards deylik, of Algeria. Algiers from this time became the chief seat of the Barbary pirates. In Oct. 1541 the emperor Charles V. sought to capture the city, but his army was defeated by the Algerians under their pasha, Hassan. Repeated attempts were made by various European nations to subdue the pirates, and in 1816 the city was bombarded by a British squadron under Lord Exmouth, assisted by Dutch men-of-war, and the corsair fleet burned. The piracy of the Algerians continued until 1830. On July 4 in that year a French army under General de Bourmont attacked the city, which capitulated on the following day. (X.)

ALGOA BAY, a wide, shallow bay between Capes Recife and Padrone, South Africa, formed by erosion of rocks of the Bokkeveld and Uitenhage series by the sea, which has left a belt of more resistant Table mountain sandstones projecting eastwards, and forming the south-west border of the bay. In the bay are St. Croix island, 33° 47' S., 25° 46' E., and Bird island, the latter yielding guano. The shores are fringed with sand dunes, which contain abundant Strandlooper remains. In 1820, British emigrants landed here and founded Port Elizabeth. Vessels drawing up to 21 ft. can discharge cargo at the jetty in calm weather. Larger ships have to anchor in the bay, and discharge into tugs and lighters.

ALGOL, a well known variable star, also designated β Persei. Its fluctuation of brightness was noticed by G. Montanari in 1669; but the Arabic name, which signifies the Demon, seems to hint that the behaviour may have been known in ancient times. The brightness varies regularly between magnitudes 2.1 and 3.2. In 1782 John Goodricke found that the variation of light was periodic and determined the period $2^d 20^h 49^m$; he suggested that the variation might be due to partial eclipses of the star by a dark body revolving round it. This hypothesis was generally accepted but it remained speculative until 1889, when H. C. Vogel demonstrated its truth in a way that can scarcely be doubted.

By spectroscopic measures of the velocity in the line of sight it was shown that the bright star was travelling round an orbit in the period named. Clearly there must be an unseen mass controlling its motion. Further the reduced light occurs when the bright star is most remote from us; that is just the time when the dark companion passes between us and the bright star and is able to hide it. About 200 variable stars of the Algol type are now known in which the change of light is due to eclipses. It should, however, be understood that this is not the sole kind of stellar variability; and in fact the majority of variable stars have a different nature (see STAR).

Algol remains of almost constant brightness for 59 hours; the remaining ten hours of the period are occupied by the eclipse, the light gradually decreasing to not much more than a third of its normal amount and then increasing again. The eclipse is partial. (In some variables a total eclipse occurs, totality being distinguished by a period of steady light at minimum.) The comparatively long duration of the eclipse shows that we have to do with two stars whose dimensions are by no means small in comparison

with the distance between them. Closer examination shows that the light is not absolutely constant during the 59 hours. The reason is that the dark component reflects (or re-radiates) light from the bright star, and thus goes through phases like the moon. Accordingly, after the eclipse is over, the total light still continues to increase a little because the "moon" is progressing from *new* to *full*. In the middle of the 59 hour interval the light dips again because there is an "eclipse of the moon"; that is to say, the bright star is then hiding its companion. The whole phenomenon is beautifully shown in the light-curve determined by J. Stebbins by means of selenium photometry.

We have spoken of the *dark* companion. In most eclipsing variables this only means comparatively dark, and the proper light of the eclipsing star is recognizable. But in Algol the companion is exceptionally dark, and it has not been possible to measure any light from it other than the reflected light above-mentioned. On theoretical grounds the companion is believed to give out less than a hundredth of the light of the principal star; but it must be noticed that Algol itself is an exceptionally bright star and its companion is actually not much fainter than our sun. From a study of the light-curve, combined with the dimensions of the orbit of the principal star obtained from spectrographic measures, a great deal can be learnt about the nature of the system; but to render the results definite an additional constant is required to be known, and through ignorance of this the dimensions formerly given have turned out to be wide of the mark.

The required datum has now been supplied by D. B. McLaughlin, who has measured the radius of Algol by an ingenious method. Near the middle of the eclipse only a crescent of the bright star is showing; this crescent will be mainly on one side of the star just before the middle phase, and on the other side after it. Now the rotation of the star causes one side to approach us and the other to recede; so that if we make measurements of radial velocity shortly before and after mid-eclipse we can determine the speed of rotation, very much as the sun's speed of rotation is determined by measuring first on the east and then on the west side of its disc. Having found the equatorial speed of rotation, we multiply by the period of rotation, and the result is the circumference of the star. In Algol the two components are close together, and there can be no doubt that the huge tidal forces will make them keep the same faces turned towards each other, so that the period of rotation must be the same as the period of revolution, viz., $2^d 21^h$. Knowing the circumference we can at once find the radius.

The following dimensions of the Algol system have been deduced:

Distance between centres.....	10,200,000 km.
Radius of bright star.....	2,140,000 km.
Radius of faint star.....	2,450,000 km.
Mass of bright star.....	$4.30 \times \text{sun's mass}$
Mass of faint star.....	$0.86 \times \text{sun's mass}$
Density of bright star.....	0.16 (water=1)
Density of faint star.....	0.02
Luminosity of bright star.....	$140 \times \text{sun}$
Distance of system.....	35 Parsecs (115 light years).

Confidence in these results is strengthened by two checks. First, the mass and luminosity are in agreement with the mass-luminosity relation which the stars are believed to obey (see STAR). Second, the luminosity is that which is usual for a star of the spectral type B 8, to which Algol belongs. It will be noticed that the fainter star has the larger radius. The distance of the system found by this method might be checked by a trigonometrical determination of parallax; but very accurate measurements would be required, and it is probable that the parallax measurements hitherto published are vitiated by perturbations due to a third component of the system.

By spectroscopic measures it is found that Algol with its satellite is describing an orbit in 1.9 years; this indicates the existence of a third member of the system. It must be at a distance of 430 million kilometres from Algol. It is intermediate in brightness between Algol and its close companion, giving about a 12th of the light of the former. It takes no part in the eclipses.

ALGONKIN, a tribe, group and family of American Indians. The tribe lived on Gatineau river east of Ottawa. The name came gradually to include related tribes or bands in Quebec and Ontario, where they now number between 3,000 and 4,000. They were friends of the French, foes of the Iroquois and British. The name was finally applied to the whole of the linguistic family of which these tribes are part. This is one of the great stocks of native North America, perhaps the largest on the continent in point of area occupied, extending around latitude 55° continuously from the Atlantic ocean to the Rocky mountains, and to the south less regularly as far as Cape Hatteras and Ohio river. This is essentially the natural region of northern woodland, whose coniferous forests the Algonkin tribes occupied almost exclusively and the deciduous ones largely.

Culturally the Algonkin lagged behind the Muskogi and Iroquois families of peoples. Where the archaeology of the north-eastern part of the continent shows distinct horizons or types, as in New York, the simpler forms can generally be identified fairly closely with historic Algonkin culture. In this area at least they therefore preceded Mound Builders and Iroquois, and in part survived them. In general the southern Algonkin tribes farmed, the northern ones were non-agricultural. Three divisions drifted into the northern Plains and became nomadic bison hunters: the Arapaho and Gros Ventre, the Blackfeet and the Cheyenne. The speech of the first two is highly specialized, indicating their separation for a long time; the Cheyenne are later comers in the Plains. In recent generations some of the Cree and Ojibwa have begun to take on the Plains type of customs.

Apart from Arapaho, Blackfoot and Cheyenne, the Algonkin languages are relatively uniform. The principal divisions are: I., Arapaho. II., Blackfoot. III., Cheyenne, nearest to the next. IV., Central-Eastern: A, Central, comprising: (1) Ojibwa type: (a) Ojibwa, Pottawatomi, Ottawa, Algonkin proper; (b) Illinois (Peoria), Miami; (2) Cree type: (a) Cree, Montagnais, probably Naskopi; (b) Menominee; (c) Sauk, Fox, Kickapoo, Shawnee, nearest to next; (3) Delaware type: Delaware, Mohegan, Wappinger, Pequot. B, Eastern, comprising: (1) Abnaki type: (a) Micmac; (b) Abnaki; (c) Pennacook; (2) Massachusetts type: Massachusetts, Wampanoag, Narraganset, Montauk, Nipmuk. Position in the family uncertain: Powhatan, Nanticoke and other south Atlantic coast tribes. (T. Michelson, *Bur. Am. Ethn. Rep.* xxviii, 1912.)

All the Algonkin languages are plastic, polysynthetic and highly elaborate in structure, and acquaintance with them unduly influenced early conceptions of the nature of American languages in general, many of which are much simpler. Of late it has seemed possible that the speech of the Beothuk of Newfoundland, of the Kootenay of British Columbia, and of the Wiyot and Yurok of the coast of California may prove to be remote branches of Algonkin.

In 1907 the aggregate population of tribes of admitted Algonkin affinity was estimated at 90,000, a sensible majority being resident in Canada, and Ojibwa and Cree making up a full half of the total.

(A. L. K.)

ALGORISM, a name applied in the middle ages to arithmetic employing the Indo-Arabic numerals. (See **ALGEBRA** for Mohammed ibn Mūsā al-Khawārizmī, who wrote *Liber Algorism*, "the Book of al-Khawārizmī.") It appeared in mediaeval French as *augrisme* and *augrime*, and was thence carried to England as *augrym* or *augrim*, as in Chaucer's *Astrolabe*, his *Testament of Love* and his *Clerk's Tale*. In Spanish it takes such forms as *al guarisma*. In the middle ages the abacists computed on the abacus (*q.v.*), while the algorists computed by algorism. Robert Recorde (*q.v.*) wrote in his *Ground of Artes* (c. 1542): "Some call it Arsemetrick, and some Augrime. . . . Both names are corruptly written: Arsemetrick for Arithmetick, as the Greeks call it, and Augrime for Algorisme, as the Arabians found it" (1646 edition). Early European writers thought that the word came from *Algus*, a king of India; thus in a manuscript of c. 1300: "Ther was a kyng of Inde the quich heyth Algor, he made this craft. And aft his name he called hit algory."

ALGUAZIL, a Spanish title often to be met in stories and plays, derived from the Arabic "*visir*" and the article "*al*." The

alguazil among the early Spaniards was a judge, and sometimes the governor of a town or fortress. In later times he has gradually sunk down to the rank of an officer of the court, who is trusted with the service of writs and certain police duties. The title has also been given to inspectors of weights and measures in market-places, and similar officials.

ALGUM or **ALMUG TREE**. The Hebrew words *Algummin* or *Almuggim* are translated *Algum* or *Almug* trees in the authorized version of the Bible (*see* 1 Kings x. 11, 12; 2 Chron. ii. 8, and ix. 10, 11); *almug* is an erroneous form (*see* Max Müller, *Science of Language*). The wood of the tree was very precious, and was brought from Ophir (probably some part of India), along with gold and precious stones, by Hiram, and was used in the formation of pillars for the temple at Jerusalem, and for the king's house; also for the inlaying of stairs, as well as for harps and psalteries. It is probably the red sanders or red sandal-wood of India (*Pterocarpus santalinus*). This tree belongs to the large family Leguminosae, sub-order Papilionaceae. The wood is hard, heavy, close-grained and of a fine red colour. It is different from the white fragrant sandal-wood, which is the produce of *Santalum album*, a tree belonging to another family, the Santalaceae.

ALHAMA DE GRANADA, southern Spain, province of Granada, 24m. S.W. of Granada. Pop. (1920) 7,591. Alhama is on a sloping shelf of limestone over a deep gorge of the river Marchan or Alhama; the rugged peaks (6,800ft.) of the Sierra de Alhama rise behind it. On Christmas Day 1884 an earthquake destroyed fine terraces of Moorish houses and 800 people, and the town was rebuilt a little way from the old site. The baths (Arabic, *alhama*=bath) near the river, continuously used since Roman times, survived. The temperature of the hot sulphurous springs is about 112°F.; and visitors come in spring and autumn for the fine scenery and cures of rheumatism and dyspepsia. In the 15th century Alhama and the neighbouring fortress of Loja (*q.v.*), were the keys of Granada.

ALHAMBRA, THE, an ancient palace and fortress of the Moorish monarchs of Granada, in southern Spain, occupying a hilly terrace on the south-eastern border of the city of Granada. This terrace or plateau extends from west-north-west to east-south-east, and covers an area of about 35 acres. It is enclosed by a strongly fortified wall, which is flanked by 13 towers. (For an account of the period to which the Alhambra belongs, *see* GRANADA [city]). The palace was built chiefly between 1248 and 1354, in the reigns of Al Ahmar and his successors, but even the names of the principal artists employed are either unknown or doubtful. The splendid decorations of the interior are ascribed to Yusef I., who died in 1354. Immediately after the expulsion of the Moors in 1492, their conquerors began, by successive acts of vandalism, to spoil the marvellous beauty of the Alhambra. Charles V. (1516-56) rebuilt portions in the style of the period, and destroyed the greater part of the winter palace to make room for a structure which has never been completed. Philip V. (1700-46) Italianized the rooms, and completed the degradation by running up partitions which blocked up whole apartments, gems of taste and patient ingenuity. In 1821 an earthquake caused further damage. The work of restoration undertaken in 1828 by the architect, José Contreras, was endowed in 1830 by Ferdinand VII.; and after the death of Contreras in 1847, it was continued with fair success by his son Rafael (d. 1890), and his grandson Mariano.

The situation of the Alhambra is one of rare natural beauty; the plateau commands a wide view of the city and plain of Granada, towards the west and north, and of the heights of the Sierra Nevada, towards the east and south. The park (Alameda de la Alhambra), which in spring is overgrown with wild-flowers and grass, was planted by the Moors with roses, oranges and myrtles; its most characteristic feature, however, is the dense wood of English elms brought hither in 1812 by the duke of Wellington.

The Moorish portion of the Alhambra resembles many mediaeval Christian strongholds in its threefold arrangement as a castle, a palace and a residential annexe for subordinates. The Alcazaba or citadel, its oldest part, is built on the isolated and

PLANS AND DRAWINGS. FROM PHOTOGRAPHS OF THE ALHAMBRA

To the black-and-white of the illustration must be added the gorgeous colour which decks the rich plaster work everywhere. The intricate arabesques glow with gold, bright blue, pure red and touches of deep green

precipitous foreland which terminates the plateau on the north-west. Only its massive outer walls, towers and ramparts are left. Beyond the Alcazaba is the palace of the Moorish kings, or Alhambra properly so-called, and beyond this, again, is the Alhambra Alta (Upper Alhambra), originally tenanted by officials and courtiers.

Access from the city to the Alhambra park is afforded by the Puerta de las Granadas (Gate of Pomegranates), a massive triumphal arch dating from the 15th century. A steep ascent leads past the Pillar of Charles V., a fountain erected in 1554, to the main entrance of the Alhambra. This is the Puerta Judiciaria (Gate of Judgment), a massive horseshoe archway, surmounted by a square tower, and used by the Moors as an informal court of justice.

The present entrance to the Palacio Arabe, or Casa Real, is by a small door from which a corridor conducts to the Patio de los Arrayanes (Court of the Myrtles), also called the Patio de la Alberca (Court of the Blessing or Court of the Pond). This court is 140ft. long by 74ft. broad, and in the centre there is a large pond set in the marble pavement, full of goldfish, and with myrtles growing along its sides. There are galleries on the north and south sides; that on the south 27ft. high, and supported by a marble colonnade. Underneath it, to the right, was the principal entrance, and over it are three elegant windows with arches and miniature pillars.

The Sala de los Embajadores (Hall of the Ambassadors) is the largest in the Alhambra, and occupies all the Torre de Comares. It is a square room, the sides being 37ft. in length, while the centre of the dome is 75ft. high. This was the grand reception room, and the throne of the sultan was placed opposite the entrance.

The celebrated Patio de los Leones (Court of the Lions) is an oblong court, 116ft. in length by 66ft. in breadth, surrounded by a low gallery supported on 124 white marble columns. A pavilion projects into the court at each extremity, with filigree walls and light domed roof, elaborately ornamented. The square is paved with coloured tiles, and the colonnade with white marble, while the walls are covered 5ft. up from the ground with blue and yellow tiles, with a border above and below enamelled blue and gold. In the centre of the court is the celebrated Fountain of Lions, a magnificent alabaster basin supported by the figures of twelve lions in white marble, not designed with sculptural accuracy, but as emblems of strength and courage.

The Sala de los Abencerrajes (Hall of the Abencerrages) derives its name from a legend according to which Boabdil, the last king of Granada, having invited the chiefs of that illustrious line to a banquet, massacred them here. This room is a perfect square, with a lofty dome and trellised windows at its base. The roof is exquisitely decorated in blue, brown, red and gold, and the columns supporting it spring out into the arch form in a remarkably beautiful manner. Opposite to this hall is the Sala de las dos Hermanas (Hall of the two Sisters), so-called from two very beautiful white marble slabs laid as part of the pavement. There is a fountain in the middle of this hall, and the roof—a dome honeycombed with tiny cells, all different, and said to number 5,000—is a magnificent example of the so-called “stalactite vaulting” of the Moors.

The original furniture of the palace is represented by the celebrated vase of the Alhambra, a splendid specimen of Moorish ceramic art, dating from 1320, and belonging to the first period of Moorish porcelain.

Of the outlying buildings in connection with the Alhambra, the foremost in interest is the Palacio de Generalife or Gíneralife (the Moorish *Jennat al Arif*, “Garden of Arif,” or “Garden of the Architect”). This villa probably dates from the end of the 13th century, but has been several times restored. The Villa de los Martires (Martyrs' Villa), on the summit of Monte Mauror, commemorates by its name the Christian slaves who were employed to build the Alhambra, and confined here in subterranean cells.

See *Plans, Elevation, Sections and Details of the Alhambra; from drawings taken on the spot by J. Goury and Owen Jones; with a*

complete translation of the Arabic inscriptions and a historical notice of the Kings of Granada, by P. de Gayangos. These two magnificent folios, though first published in London between 1842 and 1845, give the best pictorial representation of the Alhambra; Rafael Contreras, *La Alhambra, El Alcázar, y la gran Mezquita de Occidente* (Madrid, 1885); *The Alhambra*, by Washington Irving, was written in 1832, and rewritten in 1857. A well-illustrated edition was published in London in 1896.

ALHAMBRA, a city of Los Angeles county, California, U.S.A., at the entrance to the San Gabriel valley; bounded by the cities of Los Angeles, South Pasadena, and San Gabriel, and by the east side industrial area which adjoins Los Angeles. It is served by the Southern Pacific and the Pacific Electric railways, and is connected with Los Angeles by five boulevards. The population was 9,096 in 1920; and in 1930 had increased to 29,472 by the Federal census, a gain of 9,096 for the decade. Alhambra is primarily a residential city, but provision is made for industrial development in a segregated district. The principal manufactures are equipment for petroleum refineries, power apparatus, clay products, electrical goods, and beeswax and bee-keepers' supplies. The city was incorporated in 1903, and adopted a commission-manager form of government in 1914. The name was given by Benjamin D. Wilson (after whom Mt. Wilson was named) when he set aside a tract for a city out of his vast ranch holdings; and the prevailing Spanish-Moorish type of architecture is in harmony with the name. On the outskirts of Alhambra is the San Gabriel mission (founded 1771 by the Franciscans).

ALHAZEN (ál-hah'zén) [ABU ALI AL-HASAN IBN ALHASAN], Arabian mathematician of the 11th century, was born at Basra and died at Cairo in 1038. He is to be distinguished from another Alhazen who translated Ptolemy's *Almagest* in the 10th century. Having boasted that he could construct a machine for regulating the inundations of the Nile, he was summoned to Egypt by the caliph Hakim; but, aware of the impracticability of his scheme, and fearing the caliph's anger, he feigned madness until Hakim's death in 1021.

Alhazen was the first great discoverer in optics after the time of Ptolemy. According to Giovanni Battista della Porta, he first explained the apparent increase of heavenly bodies near the horizon, although Bacon gives the credit of this discovery to Ptolemy. His treatise on optics was translated into Latin by Witelo (1270), and afterwards published by F. Risner in 1572, with the title *Opticæ thesaurus Alhazeni libri VII., cum ejusdem libro de crepusculis et nubium ascensionibus*. Works on geometrical subjects were found in the *Bibliothèque nationale de Paris* in 1834 by E. A. Sédillot; other manuscripts are preserved in the Bodleian Library at Oxford and in the library of Leyden.

BIBLIOGRAPHY.—See Casiri, *Bibl. Arab. Hisp. Escur.*; J. E. Montucla, *Histoire des mathématiques* (1758); and E. A. Sédillot, *Matériaux pour l'histoire des sciences mathématiques*.

ALI, in full, 'ALI BEN ABU TALIB (c. 600–661), the fourth of the caliphs or successors of Mohammed, was born at Mecca about the year A.D. 600. His father, Abū Talib, was an uncle of the prophet, and Ali himself was adopted by Mohammed and educated under his care. As a mere boy he distinguished himself by being one of the first to declare his adhesion to the cause of Mohammed, who some years afterwards gave him his daughter Fatima in marriage. When Mohammed died without male issue, a few emigrants thought Ali to have the best claim to succeed him. Abu Bekr, Omar, and Othman, however, occupied this position before him, and it was not until A.D. 656, after the murder of Othman, that he assumed the title of caliph. Almost the first act of his reign was the suppression of a rebellion under Talha and Zobair, who were instigated by Ayesha, Mohammed's widow, a bitter enemy of Ali, and one of the chief hindrances to his advancement to the caliphate. The rebel army was defeated at the “Battle of the Camel,” near Basra, the two generals being killed, and Ayesha taken prisoner. Ali soon afterwards made Kufa his capital. His next care was to get rid of the opposition of Moawiya, who had established himself in Syria at the head of a numerous army. A prolonged battle took place in July 657 in the plain of Siffin (Suffein), near the Euphrates; the fighting was at first, it is said, in favour of Ali, when suddenly a number of the enemy, fixing copies of the Koran to the points of their spears, exclaimed

that "the matter ought to be settled by reference to this book, which forbids Moslems to shed each other's blood." The superstitious soldiers of Ali refused to fight any longer, and demanded that the issue be referred to arbitration (*see* CALIPHATE, section B. 1). Abu Musa was appointed umpire on the part of Ali, and 'Amr-ibn-el-Ass, a veteran diplomatist, on the part of Moawiya. It is said that 'Amr persuaded Abu Musa that it would be for the advantage of Islam that neither candidate should reign, and asked him to give his decision first. Abu Musa having proclaimed that he deposed both Ali and Moawiya, 'Amr declared that he also deposed Ali, and announced further that he invested Moawiya with the caliphate. This treacherous decision (658), (but *see* CALIPHATE, *ib.*) greatly injured the cause of Ali, which was still further weakened by the loss of Egypt. After much indecisive fighting, Ali found his position so unsatisfactory that according to some historians he made an agreement with Moawiya by which each retained his own dominions unmolested. It chanced, however—according to a legend, the details of which are quite uncertain—that three of the fanatic sect of the Kharijites had made an agreement to assassinate Ali, Moawiya and 'Amr, as the authors of disastrous feuds among the faithful. The only victim of this plot was Ali, who died at Kufa Jan. 24, 661, of the wound inflicted by a poisoned weapon. A splendid mosque called Meshed Ali was afterwards erected near the city, but the place of his burial is unknown. He had eight wives after Fatima's death, and in all, it is said, thirty-three children, one of whom, Hassan, a son of Fatima, succeeded him in the caliphate. His descendants by Fatima are known as the Fatimites (*q.v.*; *see* also EGYPT: *History*, Mohammedan period). The question of Ali's right to succeed to the caliphate is an article of faith which divided the Mohammedan world into two great sects, the Sunnites and the Shiites, the former denying, and the latter affirming, his right. The Turks, consequently, hold his memory in abhorrence; whereas the Persians, who are generally Shi'as, venerate him as second only to the prophet, call him the "Lion of God" (Sher-i-Khudā), and celebrate the anniversary of his martyrdom. Ali is described as a bold, noble, and generous man, "the last and worthiest of the primitive Moslems, who imbibed his religious enthusiasm from companionship with the prophet himself, and who followed to the last the simplicity of his example." It is maintained, by the other school, that his motives were throughout those of ambition rather than piety, and that, apart from the tragedy of his death, he would have been an insignificant figure in history. (*See* CALIPHATE.)

BIBLIOGRAPHY.—In the eyes of the later Moslems he was remarkable for learning and wisdom, and there are extant collections (almost all certainly spurious) of proverbs and verses which bear his name: the *Sentences of Ali* (Eng. trans., William Yule, Edinburgh, 1832); H. L. Fleischer, *Alis Hundert Sprüche* (Leipzig, 1837); the *Divan*, by G. Kuypert (Leyden, 1745, and at Bulak, 1835); C. Brockelmann, *Gesch. d. arabisch. Lit.* (vol. i., Weimar, 1899).

ALI, known as **ALI BEY** (1766–1818), the assumed name of DOMINGO BADIA Y LEBLICH, a Spanish traveller. Pretending to be a descendant of the Abbasids, Badia in 1803 set out on his travels. Under the name of Ali Bey el Abbassi, and in Muslim costume, he visited Morocco, Tripoli, Egypt, Arabia and Syria. He made the pilgrimage to Mecca, at that time in the possession of the Wahabites. In 1814, Badia published in Paris an account of his travels under the title of *Voyage d'Ali Bey en Asie et en Afrique, etc.* A few years later he set out again for Syria under the assumed name of Ali Othman and, it is said, accredited as a political agent by the French Government. He reached Aleppo, and there died, not without suspicion of having been poisoned.

An account of his Eastern adventures was published in London in 1816 entitled *Travels in Morocco, Tripoli, Cyprus, Egypt, Arabia, Syria and Turkey, between the years 1803 and 1807*.

ALI, known as **ALI PASHA** (1741–1822), Turkish pasha of Iannina, surnamed Arslan (the lion), was born at Tepeleni, Albania. His father, hereditary bey of Tepeleni, was killed by neighbouring chiefs when Ali was 14. His mother formed a brigand band to secure revenge and restitution. In the wild brigand school Ali proved an apt pupil, and recovered Tepeleni. He was then commissioned by the Turkish Government to chastise the

rebellious pasha of Scutari, whom he defeated and killed. He was then appointed lieutenant to the derwend-pasha of Rumelia, with a commission for the suppression of brigandage, and seized the opportunity to enrich himself by levying a tax on the brigands for immunity, at the same time securing indemnity for the malpractice by judicious bribes at Constantinople. In 1788 he was made pasha of Iannina.

By a combination of cunning and severity Ali made himself all-powerful in central Albania, and began to contemplate the establishment of a sea power including Albania, Greece and Thessaly which should rival in the eastern that of the dey of Algiers in the western Mediterranean. For a brief period in 1797–98 it seemed that this might be accomplished with the help of the French, who had occupied the Ionian islands, and gave Ali permission to suppress the "aristocratic" tribes of the coast. In the confused events which followed Ali abandoned his flirtation with France and French ideas, foreseeing the ultimate defeat of France. He retained the confidence of the sultan, who confirmed him in possession of the whole of Albania, and made him vali of Rumelia. In 1803 he was master of Epirus, Albania and Thessaly, while the pashaliks of Morea and Lepanto were in the hands of his sons Veli and Mukhtar. He held all the coastal towns which had once been Venetian, except Parga, which remained French in spite of a brief renewal of Ali's alliance with Napoleon in 1807. In 1814 the Pargiots rose against the French garrison, and handed it over to the British to save it from Ali, who had bought from the French commandant a promise of surrender. Ali now sent a mission to London, which was, in the end, successful. The Pargiots were compensated and removed to the Ionian islands, and the Turks took possession.

But Ali's fall was near. The Sultan Mahmud II. found a pretext in Ali's attempt to secure the murder of Pasha Bey in the precincts of the palace at Constantinople. Hurshid Pasha, the grand vizier, was entrusted with his deposition. After a polite interview with Hurshid, Ali was stabbed in the back as he left the tent.

Ali's court at Iannina was the centre of a sort of barbarous culture, in which astrologers, alchemists and Greek poets played their part, and was often visited by travellers. Amongst others, Byron came, and has left a record of his impressions in "Childe Harold's Pilgrimage," less interesting and vivid than the prose accounts of Pouqueville, T. S. Hughes and William M. Leake. Leake (iii. 259) reports a reproof addressed by Ali to the French renegade Ibrahim Effendi, who had ventured to remonstrate against some particular act of ferocity: "At present you are too young at my court to know how to comport yourself. . . . You are not yet acquainted with the Greeks and Albanians; when I hang up one of these wretches on the plane-tree, brother robs brother under the very branches: if I burn one of them alive, the son is ready to steal his father's ashes to sell them for money. They are destined to be ruled by me; and no one but Ali is able to restrain their evil propensities." This is perhaps as good an apology as could be made for his character and methods. To the wild people over whom he ruled, none was needed. He had their respect, if not their love; he is the hero of a thousand ballads; and his portrait still hangs among the *ikons* in the cottages of the Greek mountaineers.

BIBLIOGRAPHY.—Apart from the scattered references in the published and unpublished diplomatic correspondence of the period, contemporary journals and books of travel contain much interesting material for the life of Ali. Of these may especially be mentioned François C. H. L. Pouqueville, *Voyage en Morée, à Constantinople en Albanie, etc.* (1805), of which an English version by A. Plumptre was published in 1815; *ib. Voyage dans la Grèce* (1820, 1821). Pouqueville, who spent some time as French resident at Iannina, had special facilities for obtaining first-hand information, though his emotionalism makes his observations and deductions at times somewhat suspect. Very interesting also are Thomas Smart Hughes, *Travels in Greece and Albania* (2nd ed. 1830); John Cam Hobhouse (Lord Broughton), *A Journey through Albania, etc.* . . . during the years 1809–10 (1813 a new ed. 1855); William Martin Leake, *Travels in Northern Greece* (1845). *See* also Pouqueville's *Hist. de la régénération de la Grèce, 1740–1824* (1824, 3rd ed., 1825); R. A. Davenport, *Life of Ali Pasha, vizier of Epirus* (1861); and the chapter by W. Alison Phillips on "Greece and the Balkan Peninsula," vol. x. chap. vi. of *Cambridge Modern History*.

ALIAGA, a municipality (with administrative centre and 14 *barrios* or districts) of the province of Nueva Ecija, Luzon, Philippine islands, almost due west from the capital Cabanatuan and about 70m. N. by W. of Manila. Pop. (1918) 12,703, of whom 6,428 were male, 6,271 female. The white population numbered four. Literacy (based on ages from ten years up, 1918) 56.6%. It has a comparatively cool and healthful climate, and is pleasantly situated about midway between the Pampanga Grande and Pampanga Chico rivers, and in a large and fertile valley, of which the principal products are corn, rice, sugar and tobacco. The four languages spoken are Tagalog, Ilocano, Pampango and Pangasinan. There were five schools of all sorts in 1918. In 1848 Aliaga was transferred from the province of Pampanga to that of Nueva Ecija. Civil Government under the United States was organized in 1901. (J. A. R.)

ALIAS, a term used to connect the different names of a person who has passed under more than one, in order to conceal his identity or for other reasons, or to describe compendiously an adopted name.

ALIBI, in law, the defence resorted to in criminal prosecutions, where the person charged alleges that he was so far distant at the time from the place where the crime was committed that he could not have been guilty. An alibi, if substantiated, is the most conclusive proof of innocence. (See CRIMINAL LAW.)

ALICANTE, capital of the province of that name, episcopal see with modern cathedral, rising in a crescent from the bay up the low surrounding hills with white flat-roofed houses ending in an old citadel on bare rock (400ft.). Pop. (1920) 63,908. A dry and equable climate makes it a health-resort, and large suburbs have been built since 1905. The bays afford good anchorage, and large harbour works since 1902 have improved what is one of the chief ports of Spain. The trade of Alicante consists in the manufacture of cotton, linen and woollen goods, cigars, confectionery and castor oil; the importation of coal, iron, machinery, manures, timber, oak staves and fish; and the exportation of lead, fruit, farm produce and red wines, which are sent to France

north and west there are extensive calcareous mountain ranges cut by deep ravines; further south the land is more level with fertile valleys. On the coast, unhealthy salt marshes alternate with pleasant and productive *huertas* or gardens, such as those of Alicante and Denia. The Segura, the only large river, flows from the highlands of Albacete through Murcia and Orihuela. The scanty torrential rainfall makes irrigation from the Segura with its network of canals important. 40% of the area is cultivated, nearly a quarter being devoted to vines, the most important culture, producing wine and raisins from stocks immune against the phylloxera. The wine is famous in Spain and inferior kinds are sent to France to be mixed with claret. Cereals (barley first in importance, rice second) are profitable only in such irrigated lands as the Huerta de Orihuela; wheat and barley are imported from Algeria and maize from Argentina. Olives, almonds, oranges (especially in the Segura valley and on the coast), carobs and date-palms are grown in large plantations. The fruit-trees (1923), estimated at 2,500,000, gave produce worth over thirteen million pesetas, the almond, the characteristic fruit-tree of Alicante, representing six millions. Oranges are sent to England, Germany, Holland and Belgium, and other fruits to the interior of Spain. In sericulture, Alicante is second only to Murcia (1925). Stock-raising is not important, and the roads are mostly poor. Except in the Orihuela district, most of the land is in small properties and fertility and skill in cultivation have made the population dense even apart from Alicante and Alcoy. The annual value of agricultural produce is about 163 million pesetas. Mineral products include superphosphates, salt and rock-salt. Hydrochloric, nitric and sulphuric acids are made in quantities. Fine cloths, silk, cotton and woollen fabrics, lace, paper, hats, leather, earthenware, soap, oil and brandy are made. Fisheries of tunny and anchovy are active. The dialect is a variety of the Valencian. In 1920, 53.95% of the population was returned as illiterate. The principal towns (separately described) are Alicante, the capital (pop. 1920, 63,908), Crevillente (11,216), Denia (12,612), Elche (33,167), Novelda (11,994), Orihuela (37,180), and Villena (16,544).

ALICE MAUD MARY, Grand Duchess of Hesse-Darmstadt (1843-1878), second daughter and third child of Queen Victoria, was born at Buckingham Palace on April 25 1843. In the summer of 1860, at Windsor Castle, Princess Alice first met her future husband, Prince Louis of Hesse. In the following year, the House of Commons unanimously voted a dowry of £30,000 on her marriage and an annuity of £6,000 to the princess. In Dec. 1861, Princess Alice nursed her father with the utmost care during his short illness, and after his death devoted herself to comforting her mother. Her marriage took place at Osborne, on July 1, 1862.

The princess unconsciously wrote her own biography from this period in her constant letters to Queen Victoria, a selection of which, edited by Dr. Carl Sell, were printed in 1883. These letters give a complete picture of the daily life of the duke and duchess, and they also show the intense love of the latter for her husband, her mother and her native land. She visited England every year, and it was at her special request that when she died her husband, who succeeded to the throne of the duchy in 1877, laid an English flag upon her coffin. In Nov. 1878 her children and her husband contracted diphtheria, and one of the children died. The duchess, worn with sorrow and anxiety herself contracted the disease after the others had recovered, and died on Dec. 14. She left one son and four daughters: Ernest Louis, late reigning Grand Duke of Hesse (abdicated 1918); Victoria Alice, married Prince Louis of Battenberg, marquis of Milford Haven; Elizabeth Feodorovna, Grand Duchess Sergius of Russia, assassinated Sept. 1918; Irene, Princess Henry of Prussia; Alexandra Feodorovna, tsaritsa of Russia, killed July 16, 1918.

See Carl Sell, *Alice: Mittheilungen aus ihrem Leben und Briefen*, etc. (Darmstadt, 1883), with English translation by the Princess Christian, *Alice: biographical sketch and letters* (1884).

ALICE SPRINGS, a telegraph station on the overland telegraph line (Adelaide-Port Darwin) in the central southern portion of the Northern Territory, Australia. Situated near the centre of the Macdonnell ranges, 994m. from Adelaide and

A CHARACTERISTIC OLD FARMHOUSE ON THE OUTSKIRTS OF ALICANTE, CAPITAL OF THE SPANISH PROVINCE OF THAT NAME, IN THE HEART OF THE DATE-RAISING COUNTRY OF SOUTH-EASTERN SPAIN

for blending with better vintages. Fine marble is procured in the island of Plana near the coast.

Alicante was the Roman *Lucentum*; but, despite its antiquity, it has few Roman or Moorish remains. In 718, it was occupied by the Moors, who were only expelled in 1304, and made an unsuccessful attempt to recapture the city in 1331. Alicante was besieged by the French in 1709, and by the Federalists of Cartagena in 1873.

BIBLIOGRAPHY.—M. R. Garcia and A. Montero y Perez, *Ensayo biográfico bibliográfico de escritores de Alicante y de su provincia* (Alicante, 1890).

ALICANTE, seaboard province, south-eastern Spain, formed (1833) from parts of the provinces of Valencia and Murcia. Pop. (1920) 512,186; area, 2,240sq.m.; density per sq.m., 237. In the

1,105m. from Port Darwin, it lies virtually in the centre of the continent. Heavitree Gap, the largest and most conveniently situated of the characteristic gorge-like passes through the ranges, lies 4m. to the south, and upon this gap the telegraph line and a considerable stock-route traffic converge. Through this gap also will run the new railway line from Oodnadatta to Alice Springs now under construction. Alice Springs (altitude 1,926ft.) stands on the central Australian platform (average elevation c. 2,000ft.). The climate, hot in summer but fine and bracing in winter, suffers from the extremes associated with every continental position. (Mean annual temp.: 69.8°; annual range: 31.5°; diurnal range: 40–50°, sinking at times to 8–10° below freezing point in winter nights. The rainfall [average annual: c. 11in.] is erratic, variation 27.21–4.3in.).

In spite of such uncertainties of climate, and of its remoteness, Alice Springs is destined to become the centre of an extensive pastoral area, and the mineral resources (gold, mica, etc.) of the region are probably considerable.

ALIDADE, or sight rule, a ruler provided with sights and used as an accessory with the plane-table employed for topographic survey. (See SURVEYING.)

ALIEN is defined by the British Nationality and Status of Aliens Act 1914–22 as a “person who is not a British subject.” He is one who either owes allegiance to a foreign sovereign or is stateless. *Calvin’s Case* (1608) decided that natives of Scotland born before the union of the Crowns were aliens in England, but that, since allegiance is to the person of the king, those born subsequently (*post-nati*) were English subjects. But in *Isaacson v. Durant* (1886) the Court held that allegiance was due to the king, in his political and not in his personal character. Consequently, upon the separation of the Crowns of England and Hanover on the accession of Queen Victoria, Hanoverians ceased to owe allegiance to the British Crown and became aliens; and those born after the separation of the kingdoms were *a fortiori* in the same position.

Formerly, aliens in England suffered many disabilities. At common law an alien could not hold landed property, not even under lease. Until the reign of Edward I., when by charter aliens were permitted to rent houses, foreign merchants lived in lodgings. By 32 Hen. VIII. c. 16 alien artificers or handicraftsmen were forbidden to lease a dwelling house or shop. By the Naturalization Act, 1844, however, aliens were permitted to hold land or houses for residence or business for a term not exceeding 21 years, and also to take and hold personal property. They were incapable of inheriting real estate and of transmitting it by descent. By 11 & 12 William III. c. 6, natural-born subjects might derive title by descent through an alien ancestor. At common law an alien, whether the subject of a friendly or enemy state, possesses no legal right to enter British territory, but during his residence within the British dominions he owes a local allegiance to the Crown to the same extent as a British subject. Thus he is subject to British law, including that of treason. He was incapable, even when naturalized by the Act of Naturalization, of being a member of the Privy Council or of either House of Parliament, and this is still the law as to persons naturalized otherwise than under the Acts of 1870 and 1914. He was also incapable of holding any municipal office or of voting at parliamentary or municipal elections or of filling any office or place of trust, civil or military. Many of these disabilities were removed by the Naturalization Act 1870, the provisions of which were substantially re-enacted by the British Nationality and Status of Aliens Act 1914–22. By s.17 of this Act an alien may take, acquire, hold, and dispose of real and personal property as if he were a natural-born British subject; and a title to real and personal property may be derived through, from, or in succession to an alien in the same manner as through, from, or in succession to a natural-born British subject, provided that this section shall not operate so as to (1) confer any right on an alien to hold real property situated out of Great Britain; or (2) qualify an alien for any office or for any municipal, parliamentary, or other franchise; or (3) qualify an alien to be the owner of a British ship; or (4) entitle an alien to any right or privilege as a British subject, except such rights and privileges

in respect of property as are hereby expressly given to him; or (5) affect any estate or interest in real or personal property to which any person has or may be entitled, either mediately or immediately, in possession or expectancy, in pursuance of any disposition made before May 12, 1870, or in pursuance of any distribution by law on the death of any person dying before that day. But an alien may purchase a British ship, and if she is built in England to be delivered to him abroad, she is not a “British ship” within the Merchant Shipping Act 1894. By the Representation of the People Act 1918 an alien is not entitled to be registered or to vote as a parliamentary or local government elector. By s.18 of the Nationality Act of 1914 an alien is triable in the same manner as a natural-born British subject. By the Army Act 1881 an alien may with the consent of the Crown enlist in H.M. regular forces, but may not hold higher rank than that of a warrant or non-commissioned officer.

It seems to be a rule of general public law that an alien can be sent out of the realm by exercise of the Crown’s prerogative; but in modern English practice, whenever it seems necessary to expel foreigners (see EXPULSION), a special Act of parliament has to be obtained for the purpose, unless the case falls within the Extradition Acts or the Aliens Act 1905. The Acts of 1905, 1914 and 1919 prohibit the landing in Great Britain of undesirable alien steerage passengers, called in the Act “immigrants,” from ships carrying more than 20 alien steerage passengers, called in the Act “immigrant ships”; nor can alien immigrants be landed except at certain ports at which there is an “immigrant officer,” to whom power of prohibiting the landing is given, subject to a right of appeal to the immigration board of the port. The act contains a number of qualifications, and among these empowers the Secretary of State to exempt any immigrant ship from its provisions if he is satisfied that a proper system is maintained to prevent the immigration of undesirable persons. The principal test of undesirableness is not having or being in a position to obtain the means of supporting one’s self and one’s dependants, or appearing likely from disease or infirmity to become a charge on the rates, provided that the immigrant is not seeking to avoid prosecution or punishment on religious or political grounds, or persecution, involving danger of imprisonment or danger to life or limb, on account of religious belief.

The powers conferred by the Aliens Restriction Act 1914 for the exclusion, control, and deportation of aliens during a state of war or national emergency are by the Aliens Restriction (amendment) Act 1919 made permanent and further restrictions are imposed. Under the Act of 1914 by Order in Council aliens may be prohibited from landing or from embarking in Great Britain either generally or at certain places, may be deported, required to reside or remain, or forbidden to reside or remain in certain places, and required to comply with such provisions as to registration, change of abode, travelling, or otherwise as may be made by Order in Council. Under the Act of 1919 aliens inciting to sedition H.M. forces are liable on indictment to penal servitude or on summary conviction to imprisonment not exceeding three months, and for promoting industrial riot on summary conviction to imprisonment for a similar period. No alien may hold a pilotage certificate except certain certificates issued to masters or mates of French nationality. No alien may act as master, chief officer, or chief engineer of a British vessel or as skipper or second hand of a British fishing boat registered in Great Britain, except in the case of a vessel or boat employed habitually between ports outside Great Britain. Aliens certified by the Admiralty for good service are exempt from these restrictions. No alien may be employed in any capacity on board a British ship at a lower rate of pay for his rating than that current on British ships. Aliens, other than former enemy aliens habitually employed afloat in any capacity or in any climate for which they are specially fitted are exempt from the above restrictions except that relating to pay. No alien may be employed on a British ship registered in Great Britain unless he has produced satisfactory proof of his nationality. No alien may be appointed to any office or place in the Civil Service nor may he assume or use or continue the assumption or use of any name other than that by which he was ordinarily

known on Aug. 4, 1914, nor carry on business in any name other than that in which he carried on business at the said date without the consent of the Secretary of State. The Trading with the Enemy (Amendment) Act 1918 applies for a period of five years from the termination of the war . . . and thereafter until parliament otherwise determines. By s. 2 no banking business may be carried on in Great Britain (a) by a company which is an enemy-controlled corporation within the meaning of the act, or (b) by a firm or individual if the business carried on is with respect to which an order for the winding-up thereof could have been made under s. 1 of the Trading with the Enemy Act, 1916.

Enemy aliens during the time of war have no civil rights or privileges, unless they are here under the protection and by permission of the Crown. Thus an enemy alien who had registered under the Aliens Restriction Act 1914 as an enemy alien was held entitled to sue. And since an enemy alien can be sued here, he can appear and be heard in his defence, and if judgment proceed against him the appellate courts are as much open to him.

Formerly aliens acquired British nationality by special acts of parliament or became denizens by grants of letters of designation by the Crown; although both these processes are still available, aliens usually have since the Act of 1844 applied to the Home Secretary for certificates of naturalization. (H. H. L. B.)

See Pitt Cobbett, *Cases and Opinions on International Law*, vol. ii. 4th ed. (1922); J. A. Foote, *Private International Law*, 5th ed. (1925); L. F. L. Oppenheim, *International Law*, vol. ii., 4th ed. (1926).

In the United States state legislation has widely enabled aliens to hold real property by grant or devolution. Treaties have also been negotiated assuring aliens of the contracting parties reciprocal rights to hold land. In instances, however, such as the Pacific Coast Japanese land legislation, state statutes have prohibited specific types of aliens from owning or leasing land. *Terrace v. Thompson*, 263 U.S. 197. Aliens are also entitled generally to the same protection that the law affords citizens, but discriminations between aliens and citizens can constitutionally be made wherever such differences of treatment are grounded upon a rational basis. Thus statutes forbidding the entry of aliens into certain trades and professions, prohibiting aliens from owning firearms, or distinguishing between aliens and citizens in the administration of fish and game laws, are common. Statutes again may incapacitate aliens from holding public offices entitling them to public emoluments or to the right of suffrage. Distinctions are commonly drawn between declarants and non-declarants, i.e., those aliens who have manifested their intention to become citizens and those merely resident in the country. Control over the naturalization of aliens is vested in the federal government though state agencies are employed concurrently with federal in the process of naturalizing aliens. Deportation and exclusion lies with the federal government. (See IMMIGRATION; NATURALIZATION.) (J. M. LA.)

ALIENATION, the act or fact of being estranged, set apart or separated. In law the word is used for the act of transfer of property by voluntary deed and not by inheritance. In regard to church property the word has come to mean a transfer from religious to secular ownership. See also **INSANITY**.

ALIEN CORPORATION, a corporation doing business in one country but having its organization and charter in another country, e.g., a Canadian, English or French corporation doing business in the United States. The various State statutes do not make any distinction between corporations incorporated in foreign countries and those incorporated in other States of the Union, denominating all "foreign corporations" as distinguished from its own corporations known as "domestic corporations."

ALIEN-HOUSES, religious houses in England belonging to foreign ecclesiastics, or under their control; generally they were built where property had been left by donors to foreign orders in order to purchase prayers for their souls. There were more than 100 in England; many were suppressed by Henry V. and the rest by Henry VIII.

ALIENIST, one who specializes in the study of mental diseases, which are often included in the generic name "Alienation." (See **INSANITY**.)

ALIGARH, a city and district of British India in the Agra division of the United Provinces. The city (pop. 66,963 in 1921)

is also known as Koil. There are several flour-mills, cotton-presses and an important dairy farm. Aligarh fort, situated on the Grand Trunk road, consists of a regular polygon, surrounded by a very broad and deep ditch. It became a key fortress under Sindhia in 1759, and was the depot where he drilled and organized his battalions in the European fashion with the aid of De Boigne. It was captured from the Mahrattas by Lord Lake's army, in September 1803. In modern times the chief pride of Aligarh is its associations with Western education for Mohammedans. The enlightened pioneer was Sir Sayyad Ahmad Khan (d. 1898), who founded in 1864 an institute for the translation and study of Western literature. This he steadily, and in face of much orthodox opposition, developed into the Mohammedan Anglo-Oriental college and school. It attracted students from all over India and from outer Asia, and had a profound influence on the intellectual and political progress of Indian Mohammedans. In 1920 it was advanced to the status of a university.

The district of Aligarh has an area of 1,946sq.m., and a population (1921) of 1,061,745. It is nearly a level plain, but with a slight elevation in the centre, between the two great rivers the Ganges and Jumna. The only other important river is the Kali Nadi, which traverses the entire length of the district from north-east to south-west. The chief trading centre is Hathras, where there are several factories for ginning and pressing cotton.

ALIGNMENT or **ALINEMENT**, the way in which the line runs (from Fr. *à* and *ligne*, the Lat. *linea*, a line); an expression used in surveying, drawing, and in military arrangements, the alignment of a regiment or a camp meaning the situation when drawn up in line or the relative position of the tents. The alignment of a rifle has reference to the way of getting the sights into line with the object, so as to aim correctly.

ALIMENT, a synonym for "food," literally or metaphorically. The word has also been used in the same legal sense as **ALIMONY** (*q.v.*). Aliment, in Scots law, is the sum paid or allowance given in respect of the reciprocal obligation of parents and children, husband and wife, grandparents and grandchildren, to contribute to each other's maintenance. The term is also used in regard to a similar obligation of other parties, as of a sequestrated estate to aliment the bankrupt, the payments by parishes to paupers, etc. Alimentary funds, whether of the kind above mentioned, or set apart as such by the deed of a testator, are intended for the mere support of the recipient, and are not attachable by creditors.

ALIMENTARY CANAL, in anatomy. The alimentary canal is the digestive tract from the mouth to the anus. It is some 25 to 30ft. long, and the food, in its passage, passes through the following parts one after the other: mouth, pharynx, oesophagus, stomach, small intestines, caecum, large intestines, rectum and anus. Into this tube at various points the salivary glands, liver and pancreas pour their secretions by special ducts. As the mouth (*q.v.*) and pharynx (*q.v.*) are separately described, the detailed description will here begin with the oesophagus or gullet.

The *oesophagus*, a muscular tube lined with mucous membrane, stretches from the lower limit of the pharynx, at the level of the cricoid cartilage, to the cardiac orifice of the stomach. It is about 10in. long (25 cm.) and $\frac{1}{2}$ in. to 1in. in diameter. At first it lies in the lower part of the neck, then in the thorax, and lastly, for about an inch, in the abdomen. As far as the level of the fourth or fifth thoracic vertebra it lies behind the trachea, but when that tube ends, it is in close contact with the pericardium, and, at the level of the tenth thoracic vertebra, passes through the oesophageal opening of the diaphragm (*q.v.*), accompanied by the two vagi nerves, the left being in front of it and the right behind. In the abdomen it lies just behind the left lobe of the liver. Both in the upper and lower parts of its course it lies a little to the left of the mid line. Its mucous membrane is thrown into a number of longitudinal pleats to allow stretching.

The *stomach* is an irregularly pear-shaped bag, situated in the upper and left part of the abdomen. When moderately distended the thick end of the pear or *fundus* bulges upward and to the left, while the narrow end is constricted to form the *pylorus*, by means

of which the stomach communicates with the small intestine. The *cardiac orifice*, where the oesophagus enters, is placed about a third of the way along the upper border from the left end of the fundus, and, between it and the pylorus; the upper border is concave and is known as the *lesser curvature*. From the cardiac to the pyloric orifice, round the lower border, is the *greater curvature*. The stomach has in front of it the liver (see fig. 1), the

FIG. 1.—DIAGRAM OF THE ARRANGEMENT OF THE INTERNAL ORGANS AS SEEN ON REMOVAL OF FRONT ABDOMINAL WALL

diaphragm and the anterior abdominal wall, while behind it are the pancreas, left kidney, left adrenal, spleen, colon and mesocolon. When the stomach is empty it contracts into a tubular organ, and the transverse colon ascends to occupy the vacant space.

The *pylorus* is an oval opening, averaging $\frac{1}{2}$ in. in its long axis but capable of considerable distension; it is formed by a special development of the circular muscle layer of the stomach, and during life is tightly closed, except during the periodic escape of gastric contents into the duodenum. The mucous membrane of the stomach is thrown into pleats or rugae when the organ is not fully distended, while between these it has a mammillated appearance.

Superficial to the mucous coat is a submucous, consisting of loose connective tissue, while superficial to this are three coats of unstriated muscle, the inner oblique, the middle circular and the outer longitudinal. The peritoneal coat is described in the article on the coelom and serous membranes.

The *small intestine* is a tube, from 22 to 25 ft. long, beginning at the pylorus and ending at the *ileo-caecal valve*; it is divided into duodenum, jejunum and ileum.

The *duodenum* is from 9 to 11 in. long and forms a horseshoe or C-shaped curve, encircling the head of the pancreas. It differs from the rest of the gut in being retroperitoneal. Its first part is horizontal and lies behind the fundus of the gall-bladder, passing backward and to the right from the pylorus. The second part runs vertically downward in front of the hilum of the right kidney, and into this part the pancreatic and bile ducts open. The third part runs horizontally to the left in front of the aorta and vena cava, while the fourth part ascends to the left side of the second lumbar vertebra, after which it bends sharply downward and forward to form the duodeno-jejunal flexure.

The *jejunum* forms the upper two-fifths of the rest of the small intestine; it, like the ileum, is thrown into numerous convolutions and is attached by the mesentery to the posterior abdominal wall. (See COELOM and SEROUS MEMBRANES.)

The *ileum* is the remaining three-fifths of the small intestine,

though there is no absolute point at which the one ends and the other begins. Speaking broadly, the jejunum occupies the upper and left part of the abdomen below the subcostal plane (see ANATOMY: *Superficial and Artistic*), the ileum the lower and right part. At its termination the ileum opens into the large intestine at the ileo-caecal valve.

The *caecum* is a blind sac occupying the right iliac fossa and extending down some 2 or 3 in. below the ileo-caecal junction. From its posterior and left surface the *vermiform appendix* protrudes, and usually is directed upward and to the left. This worm-like tube is blind at its end and is usually 3 or 4 in. long. Its internal opening into the caecum is about 1 in. below that of the ileum. On transverse section it is seen to be composed of (1) an external muscular coat, (2) a submucous coat, (3) a mass of lymphoid tissue, which appears after birth, and (4) mucous membrane. In many cases its lumen is wholly or partly obliterated, though this is probably due to disease. Guarding the opening of the ileum into the caecum is the *ileo-caecal valve*, which consists of two cusps projecting into the caecum; of these the upper forms a horizontal shelf, while the lower slopes up to it obliquely. At birth the caecum is a cone, the apex of which is the appendix; it is bent upon itself to form a U, and sometimes this arrangement persists throughout life.

The *ascending colon* runs up from the caecum at the level of the ileo-caecal valve to the hepatic flexure beneath and behind the right lobe of the liver; it is about 8 in. long and posteriorly is in contact with the abdominal wall and right kidney. It is covered by peritoneum except on its posterior surface (see fig. 1).

The *transverse colon* is variable in position, depending largely on the distension of the stomach, but usually corresponding to the subcostal plane (see ANATOMY: *Superficial and Artistic*). On the left side of the abdomen it ascends to the splenic flexure, which may make an impression on the spleen (see DUCTLESS GLANDS), and is bound to the diaphragm opposite the 11th rib by a fold of peritoneum. The peritoneal relations of this part are discussed in the article on the coelom and serous membranes.

The *descending colon* passes down in front of the left kidney and left side of the posterior abdominal wall to the crest of the ilium; it is about 6 in. long and is usually empty and contracted while the rest of the colon is distended with gas; its peritoneal relations are the same as those of the ascending colon, but it is more likely to be completely surrounded.

The *iliac colon* stretches from the crest of the ilium to the inner border of the psoas muscle, lying in the left iliac fossa, just above and parallel to Poupart's ligament. Like the descending, it is usually uncovered by peritoneum on its posterior surface. It is about 6 in. in length.

The *pelvic colon* lies in the true pelvis and forms a loop, the two limbs of which are superior and inferior while the convexity reaches across to the right side of the pelvis. In the foetus this loop occupies the right iliac fossa, but, as the caecum descends and enlarges and the pelvis widens, it is usually driven out of this region. The distal end of the loop turns sharply downward to reach the third piece of the sacrum, where it becomes the rectum. Formerly the iliac and pelvic colons were spoken of as the *sigmoid flexure*.

The *rectum*, according to modern ideas, begins in front of the third piece of the sacrum. It ends in a dilatation or *rectal ampulla*, which is in contact with the back of the prostate in the male and of the vagina in the female and is in front of the tip of the coccyx. The rectum is not straight, as its name would imply, but has a concavity forward corresponding to that of the sacrum and coccyx.

At the end of the pelvic colon the mesocolon ceases, and the rectum is then only covered by peritoneum at its sides and in front; lower down the lateral covering is gradually reflected off and then only the front is covered. About the junction of the middle and lower thirds of the tube the anterior peritoneal covering is also reflected off on to the bladder or vagina, forming the *rectovesical pouch* in the male and the *pouch of Douglas* in the female. This reflexion is usually about 3 in. above the anal aperture.

The *anal canal* is the termination of the alimentary tract, and runs downward and backward from the lower surface of the rectal ampulla between the levatores ani muscles. It is about an inch long and its lateral walls are in contact.

Structure of the Intestine.—The intestine has four coats: serous, muscular, submucous and mucous. The serous or peritoneal coat has already been described wherever it is present. The muscular coat consists of unstriated fibres arranged in two layers, the outer longitudinal and the inner circular (*see fig. 2*). In the large intestine the longitudinal fibres, instead of being arranged evenly round the tube as they are in the small, are gathered into

FIG. 2.—DIAGRAM SHOWING STRUCTURE OF THE INTESTINAL WALL. Upper left is the large intestine; upper right is the duodenum, or first portion of the small intestine; below is the small intestine

three longitudinal bands called *taeniae* (*see fig. 1*); by the contraction of these the large intestine is thrown into a series of *sacculi* or slight pouches. The *taeniae* in the caecum all lead to the vermiform appendix, and form a useful guide to this structure. In the rectum the three *taeniae* once more become evenly arranged over the whole surface of the bowel, but more thickly on the anterior and posterior parts. The circular layer is always thicker than the longitudinal; in the small intestine it decreases in thickness from the duodenum to the ileum, but in the large it gradually increases again, so that it is thickest in the duodenum and rectum.

The submucous coat is very strong and consists of loose areolar tissue in which the vessels break up.

The mucous coat is thick and vascular (*see fig. 2*); it consists of an epithelial layer nearest the lumen which forms the intestinal glands (*see also the articles EPITHELIAL and ENDOTHELIAL*). External to this is the *basement membrane*, outside which is a layer of retiform tissue, and this is separated from the submucous coat by a very thin layer of unstriated muscle called the *muscularis mucosae*. In the duodenum and jejunum the mucous membrane is thrown into a series of transverse pleats called *valvulae conniventes* (*see fig. 3*); these begin about an inch from the pylorus and gradually fade away as the ileum is reached. About 4 in. from the pylorus the common bile and pancreatic ducts form a papilla, above which one of the *valvulae conniventes* makes a hood and below which a vertical fold, the *frenulum*, runs downward. The surface of the mucous membrane of the whole of the small intestine has a velvety appearance, due to the presence of closely-set, minute, thread-like elevations called *villi* (*see fig. 2*). Throughout the whole length of the intestinal tract are minute masses of lymphoid tissue called *solitary glands* (*see fig. 2*); these are especially numerous in the caecum and appendix, while in the ileum they are collected into large oval patches, known as

agminated glands or *Peyer's patches*, the long axes of which, from $\frac{1}{2}$ in. to 4 in. long, lie in the long axis of the bowel. They are always found in that part of the intestine which is farthest from the mesenteric attachment. In the interior of the rectum three shelf-like folds, one above the other, project into the cavity and correspond to the lateral concavities or kinks of the tube. They are not in the same line and the largest is usually on the

CUNNINGHAM, "TEXT-BOOK OF ANATOMY," COURTESY OF OXFORD MEDICAL PUBLICATIONS
FIG. 3.—CIRCULAR FOLDS IN THE MUCOUS MEMBRANE OF THE SMALL INTESTINE THAT INCREASE THE SECRETORY AND ABSORBENT SURFACE

right side. They are known as the *plicae recti* or *valves of Houston*. In the anal canal are four or five longitudinal folds called the *columns of Morgagni*. (For further details, *see Quain's Anatomy*, 1896; *Gray's Anatomy*, 1926; *Cunningham's Anatomy*, Edinburgh 1922).

Embryology.—The greater part of the alimentary canal is formed by the closing-in of the entoderm to make a longitudinal tube, ventral and parallel to the notochord. This tube is blind in front and behind (cephalad and caudad), but the middle part of its ventral wall is for some distance continuous with the wall of the yolk-sac, and this part of the canal, which at first opens into the yolk-sac by a very wide aperture, is called the *mid gut*. The part in front of it, which lies dorsal to the heart, is the *fore gut*, while the part behind the aperture of the yolk-sac is the *hind gut*.

The pharynx, oesophagus, stomach and part of the duodenum are developed from the fore gut, a good deal of the colon and the rectum from the hind gut, while the mid gut is responsible for the rest. The cephalic part of the fore gut forms the pharynx (*q.v.*), and about the fourth week the stomach appears as a fusiform dilatation in the straight tube. Between the two the oesophagus gradually forms as the embryo elongates. The opening into the yolk-sac, which at first is very wide, gradually narrows, as the ventral abdominal walls close in, until in the adult the only

FIG. 4.—THE INTESTINAL TRACT OF A BIRD

indication of the connection between the gut and the yolk-sac is the very rare presence (about 2%) of Meckel's diverticulum. The stomach soon shows signs of the greater and lesser curvatures, the latter being ventral, but maintains its straight position. About the sixth week the caecum appears as a lateral diverticulum, and, until the third month, is of uniform calibre; after this period the terminal part ceases to grow at the same rate as the proximal, and so the vermiform appendix is formed. The mid gut forms a loop with its convexity toward the diminishing *vitelline duct*, or remains of the yolk-sac, and until the third month it protrudes

into the umbilical cord. The greater curvature of the stomach grows more rapidly than the lesser, and the whole stomach turns over and becomes bent at right angles, so that what was its left surface becomes ventral. This turning over of the stomach throws the succeeding part of the intestine into a *duodenal loop*, which at first has a dorsal and ventral mesentery (see COELOM AND SEROUS MEMBRANES). The intestine now grows very rapidly and is thrown into a series of coils; the caecum ascends and passes to the right ventral to the duodenum, and presses it against the dorsal wall of the abdomen; then it descends toward its permanent position in the right iliac fossa.

From the ventral surface on the hinder (caudal) closed end of the intestinal tube the *allantois* grows to form the placenta and bladder (see URINARY SYSTEM, REPRODUCTIVE SYSTEM and PLACENTA), and this region is the *cloaca* into which the alimentary, urinary and generative canals or ducts all open, but later two lateral folds appear which, by their union, divide the cloaca into a ventral and a dorsal part, the former being genito-urinary and the latter alimentary or intestinal. In this way the rectum or dorsal compartment is shut off from the genito-urinary. Later an ectodermal invagination at the hind end of the embryo develops and forms the anal canal; this is the *proctodaeum*, and for some time it is separated from the hind (caudal) end of the rectal part of the *mesodaeum* (or part of the intestinal canal formed from the mesoderm) by a membrane called the *anal membrane*. This is eventually absorbed and the digestive tract now communicates with the surface by the anus.

Comparative Anatomy.—The primitive condition of the vertebrate alimentary canal may be described as a straight, simple tube, consisting of an anterior portion, formed by an ectodermal invagination, a long median portion lined by endoderm, and a short posterior portion formed by ectodermal invagination. In the lower vertebrates the primitive tube subserved also the purpose of respiration, and traces of the double function remain in the adult structure of all vertebrates (see MOUTH, PHARYNX). In fish, the pharynx, or branchial region, suddenly becomes narrower, posterior to the gill-slits, to form the oesophagus; in higher animals the oesophagus, in the adult, is separated from the primitive pharyngeal region and lies dorsal to it. Probably, in the primitive vertebrata, the entire alimentary canal was lined with ciliated cells. Traces of this ciliation persist in many living forms.

The *oesophagus* is essentially merely a passage, as straight as may be, from the pharynx to the stomach, varying in length with the length of the neck and thoracic regions in different animals, and in calibre with the nature of the food. It is almost invariably lined with a many-layered epithelium, forming a tough coating, readily repaired and not easily damaged by hard food masses. There are few exceptions to this structural and functional simplicity. In fishes (see ICHTHYOLOGY, *Anatomy*) the swim-bladder is developed as a dorsal outgrowth of the oesophagus and may remain in open connection with it. In many birds part of the oesophagus may be temporarily dilated, forming a "crop," as for instance in birds of prey and humming birds. In the flamingo, many ducks, storks and the cormorant the crop is a permanent although not a highly specialized enlargement. Finally, in the vast majority of seed-eating birds, in gallinaceous birds, pigeons, sandgrouse, parrots and many *Passeres*, particularly the finches, the crop is a permanent globular dilatation, in which the food is retained for a considerable time, mixed with a slight mucous secretion, and softened and partly macerated by the heat of the body. Many birds feed their young from the soft contents of

the crop, and in pigeons, at the breeding season, the cells lining the crop proliferate rapidly and are discharged as a soft cheesy mass into the cavity, forming the substance known as pigeon's milk.

Stomach.—Where the oesophagus passes into the stomach, the lining wall of the alimentary tract changes to a mucous epithelium, consisting of a single layer of endodermal cells, frequently thrown into pits or projecting as processes; from being chiefly protective, it has become secretory and absorbing, and maintains this character nearly to the anus. The fundamental form of the stomach is a sac-like enlargement of the canal, the whole forming an enlarged bent tube. At the distal end of the tube the intestinal tract proper begins, and the two regions are separated by a muscular constriction. In fishes the stomach may be a simple bent tube, or an expanded, globular or elongated sac. In *Batrachia* and *Reptilia* it is in most cases a simple sac, marked off from the oesophagus only by increased calibre. In the *Crocodylia*, however, the anterior portion of the stomach is much enlarged and very highly muscular, the muscles radiating from a central tendinous area on each of the flattened sides. The cavity is lined by a hardened secretion and contains pebbles and gravel for mechanical trituration of the food, so that the resemblance to the gizzard of birds is well marked. This muscular chamber leads by a small aperture into a distal, smaller and more glandular chamber. In birds the stomach exhibits two regions, an anterior glandular region, the proventriculus, the walls of which are relatively soft and contain enlarged digestive glands. The distal region (gizzard) is larger and is lined in most cases by a more or less permanent membrane which is thick and tough in birds with a muscular gizzard, very slight in the others.

In mammals, the primitive form of the stomach consists of a more or less globular or elongated expansion of the oesophageal region, forming the cardiac portion, and a forwardly curved, narrower pyloric portion, from which the duodenum arises. The whole wall is muscular, and the lining membrane is richly glandular. In many mammals one, two or three protrusions of the cardiac region occur, whilst in the manatee and in some rodents the cardiac region is constricted off from the pyloric portion. In the *Artiodactyla* the stomach is always complex, the complexity reaching a maximum in ruminating forms. In the chevrotains, which in many other respects show conditions intermediate between non-ruminant artiodactyles and true ruminants, the oesophagus opens into a wide cardiac portion, incompletely di-

FIG. 5.—THE INTESTINAL TRACT OF THE FOX

FIG. 6.—THE INTESTINAL TRACT OF THE WALLABY

vided into four chambers. Three of these, towards the cardiac extremity, are lined with villi and correspond to the *rumen* or paunch; the fourth, which lies between the opening of the oesophagus and the pyloric portion of the stomach, is the ruminant *reticulum* and its wall is lined with very shallow "cells." The fourth or true pyloric chamber is an elongated sac with smooth glandular walls and is the *abomasum*, or rennet sac. In the camel the rumen forms an enormous globular paunch with villous walls and internally showing a trace of division into two regions. It is well marked off from the reticulum, the "cells" of which are extremely deep, forming the well-known water-chambers. In the true ruminants, the rumen forms a capacious, villous reservoir, nearly always partly sacculated, into which the food is

passed rapidly as the animal grazes. The food is subjected to a rotary movement in the paunch, and is thus repeatedly subjected to moistening with the fluids secreted by the reticulum, as it is passed over the aperture of that cavity, and is formed into a rounded bolus. The food bolus, when the animal is lying down after grazing, is passed into the oesophagus and reaches the mouth by antiperistaltic contractions of the oesophagus. After prolonged mastication and mixing with saliva, it is again swallowed,

FIG. 7.—THE INTESTINAL TRACT OF THE TAPIR

but is now passed into the psalterium, which, in true ruminants, is a small chamber with conspicuous longitudinal folds. Finally it reaches the large abomasum where the last stages of gastric digestion occur.

In the *Cetacea* the stomach is different from that found in any other group of mammals. The oesophagus opens directly into a very large cardiac sac the distal extremity of which forms a long caecal pouch. At nearly the first third of its length this communicates by a narrow aperture with the elongated, relatively narrow pyloric portion. The latter is convoluted and constricted into a series of chambers that differ in different groups of *Cetacea*. In most of the *Marsupialia* the stomach is relatively simple; in the kangaroos, on the other hand, the stomach is divided into a relatively small, caecal cardiac portion and an enormously long sacculated and convoluted pyloric region, the general arrangement of which closely recalls the large caecum of many mammals.

Intestinal Tract.—It is not yet possible to discuss the general morphology of this region in vertebrates as a group, as, whilst the modifications displayed in birds and mammals have been compared and studied in detail, those in the lower groups have not yet been systematically co-ordinated.

Fishes.—In the *Cyclostomata*, *Holocephali* and a few *Teleostei* the course of the gut is practically straight from the pyloric end of the stomach to the exterior, and there is no marked differentiation into regions. In the *Dipnoi*, a contracted sigmoid curve between the stomach and the dilated intestine is a simple beginning of the complexity found in other groups. In very many of the more specialized teleosteans the gut is much convoluted, exhibiting a series of watchspring-like coils. In a number of different groups, increased surface for absorption is given, not by increase in length of the whole gut, but by the development of an internal fold known as the spiral valve. A set of organs peculiar to fish, known as the *pyloric caeca*, is present in numbers ranging from one to nearly 200 in the vast majority of fish. These are outgrowths of the intestinal tract near the pyloric extremity of the stomach, and their function is partly glandular, partly absorbing.

In the *Batrachia* the course of the intestinal tract is nearly straight from the pyloric end of the stomach to the cloaca, in the case of the perennibranchiates there being no more than a few simple loops between the expanded "rectum" and the straight portion that leaves the stomach.

In fishes, batrachians and reptiles the intestinal tract is swung from the dorsal wall of the abdominal cavity by a mesentery

which is incomplete on account of secondary absorption in places. There are also traces, more abundant in the lower forms, of the still more primitive ventral mesentery.

Intestinal Tract in Birds and Mammals.—The primitive gut must be supposed to have run backwards from the stomach to the cloaca suspended from the dorsal wall of the body-cavity by a dorsal mesentery. This tract, in the course of phylogeny of the common ancestors of birds and mammals, became longer than the straight length between its extreme points and, consequently, was thrown into a series of folds. The mesentery grew out with these folds, but the presence of adjacent organs, the disturbance due to the outgrowth of the liver, and the secondary relations brought about between different portions of the gut, as the out-growing loops invaded each other's localities, disturbed the primitive simplicity. Three definite regions of outgrowth, however, are to be recognized in the actual disposition of the gut in existing birds and mammals. The first of these is the *duodenum*. The second portion is *Meckel's tract*. It consists of the part generally known as the small intestines, the *jejunum* and *ileum* of human anatomy, and stretches from the distal end of the duodenum to the caecum or caeca. It is the chief absorbing portion of the gut, and in nearly all birds and mammals is the longest portion. It represents, however, only a very small part of the primitive straight gut, corresponding to not more than two or three somites of the embryo. The third portion of the gut should be termed the *hind-gut*, and lies between the caecum or caeca and the anus, corresponding to the large intestines, colon and rectum of human anatomy. It is formed from a much larger portion of the primitive straight gut than the duodenum and Meckel's tract together, and its proximal portion, in consequence, lies very close to the origin of the duodenum.

Adaptations of the Intestinal Tract to Function.—The chief business of the gut is to provide a vascular surface to which the prepared food is applied so that the nutritive material may be absorbed into the system. Overlying and sometimes obscuring

FIG. 8.—THE INTESTINAL TRACT OF THE GIRAFFE

the morphological patterns of the gut, are many modifications correlated with the nature of the food. Thus in birds and mammals alike there is a direct association of herbivorous habit with great relative length of gut. In fish-eating birds and mammals, the gut is very long, with a thick wall and a relatively small calibre, whilst there is a general tendency for the regions of the gut to be slightly or not at all defined. In fruit-eating birds the gut is strikingly short, wide and simple, whilst a similar change has not taken place in frugivorous mammals. Carnivorous birds and mammals have a relatively short gut.

The Colic Caeca.—These paired or single organs lie at the junction of the hind-gut with Meckel's tract and are homologous in birds and mammals although their apparent position differs in the majority of cases in the two groups. The caeca are hollow out-growths of the wall of the gut, the blind ends being directed forwards. They vary in size within very wide limits and there is no invariable connection between the nature of the food and

FIG. 9.—THE INTESTINAL TRACT OF THE GORILLA

the degree of their development. The caecal wall is in most cases highly glandular and contains masses of lymphoid tissue. In birds and in mammals this tissue may be so greatly increased as to transform the caecum into a solid or nearly solid sac.

ALIMENTARY SYSTEM, DISEASES OF THE. Great advance in our knowledge of these diseases during recent years may be attributed chiefly to three factors: (1) the opportunities of observation afforded by the performance of surgical operations on the abdomen—the study, as it has been termed, of "the pathology of the living"; (2) an improved X-ray technique; (3) the introduction of biochemical tests for estimating the "physiological efficiency" of important organs such as the stomach, pancreas, and liver. The information gained by these methods has rendered diagnosis of diseases of the alimentary system more precise (see DIAGNOSIS), but has not proportionately advanced their treatment except by surgical operation.

The Oesophagus.—In no section of the alimentary canal have the X-rays (see X-RAYS) proved to be of greater value in diagnosis than in the oesophagus, and the indications they afford have been rendered more precise by direct inspection of the interior of the gullet by the oesophagoscope. The commonest symptom of disease of the oesophagus is difficulty in swallowing (*dysphagia*) which results from its obstruction. This is most frequently due to cancer, which chiefly occurs in men and is generally situated at the lower end of the tube where it joins the stomach, though it may also occur at the entrance or at an intermediate point opposite the bifurcation of the trachea. Functional obstruction is much rarer and occurs at the lower end, being due either to a spasm of the muscular sphincter at the entrance to the stomach, or to a failure of the muscular ring to relax as the food passes on (so-called "*achalasia*"). However brought about, the obstruction leads eventually to "idiopathic dilatation" of the oesophagus (*oesophagectasia*).

This variety of obstruction occurs in women perhaps oftener than in men and is compatible with comparatively good health. It is treated by dilatation with bougies passed through the mouth

or, sometimes, by stretching the lower end of the oesophagus by means of instruments introduced through an incision in the stomach. *Diverticula*, or pouches, are a still rarer cause of obstruction which can be recognized by X-ray examination.

The Stomach.—Cancer still remains the most serious disease of the stomach (see CANCER) and has increased rather than diminished in frequency in the last few years. It is commonest in men in the fifth and sixth decades of life and may be situated at the pylorus, which is the most frequent site, at the cardiac orifice (rarest), or in the body of the organ. Its early diagnosis, in time to afford a chance of cure by operation, is still a matter of difficulty, but improved X-ray technique is helping to solve the problem. The so-called "leather-bottle stomach" (*limitis plastica*) is now known to be generally due to diffuse cancerous infiltration.

Our knowledge of the next most serious disease of the stomach (gastric ulcer) has been rendered much more precise in recent years mainly by the work of the surgeons. Ulcer occurs in two forms, the acute and the chronic. Acute ulcers are usually multiple and may appear in the course of any septic infection, but when developing "idiopathically" they are most often met with in young women; chronic ulcers, on the other hand, are commoner in men of middle age, and are nearly always solitary. Acute ulcers are apt to perforate and may also cause profuse haemorrhage; chronic ulcers rarely perforate; but they, too, often bleed. The older statistics according to which "gastric ulcer" was chiefly a disease of women, were the result of including all the "acute" cases; the term as now usually employed refers to the chronic ulcer, chiefly a disease of men. The acute ulcer of young women is less often met with in recent years than it was formerly. The chief symptoms of the acute variety of ulcer are pain immediately after taking food, vomiting and, not uncommonly, haematemesis, with comparatively little disturbance of the general health. The chronic ulcer causes pain which occurs very punctually from one to two hours after meals while vomiting and haematemesis are less often met with. Some degrees of weakness, wasting, and anaemia are apt to be present. The symptoms of the chronic ulcer recur in attacks lasting a few weeks with long periods of more or less complete freedom from discomfort between.

When the chronic ulcer is situated at the pylorus it leads to gradual occlusion of the latter with consequent dilatation of the stomach; when situated in the body of the organ it may bring about an "hour-glass" constriction. The most serious change which a chronic ulcer can undergo, however, is its conversion into a cancer. The frequency with which such a transformation occurs is disputed, but that there is a real risk of it, all surgeons are now agreed, and its possibility is one of the chief arguments for the surgical treatment of all cases of chronic ulcer. On the other hand there is no place for surgery in the treatment of the acute ulcer unless perforation has taken place. Haemorrhage from an acute ulcer is rarely fatal and is now never treated by operation; the question of operation in bleeding from a chronic ulcer is still *sub judice*, but opinion is moving in favour of it, transfusion being performed first if necessary.

Chronic ulcer of the duodenum is closely akin to chronic gastric ulcer. Over 80% of the cases are in males. As in gastric ulcer the symptoms occur in attacks lasting a few weeks and often separated by long intervals of complete freedom. Pain is the chief symptom and tends to come on when the stomach is empty and to be relieved by taking more food—hence the term "hunger pain" applied to it. Vomiting is very rare and the chief complications are perforation, which is much commoner than in chronic gastric ulcer, and haemorrhage which may lead both to vomiting of blood and its passage from the bowel (*melaena*). The ulcer is usually situated on the anterior wall of the first part of the duodenum and is apt, after it has been present for a long time, to lead to narrowing of the outlet of the stomach. On the other hand chronic duodenal ulcers—unlike gastric—never become malignant.

Gastric and duodenal ulcers (*q.v.*) are sometimes spoken of together as "peptic ulcers," and our knowledge of the patho-

genesis of the peptic ulcer has advanced considerably, as the result of the work of Bolton in Great Britain and of Rosenow in America. The first stage in the development of an ulcer is the formation of a small area of necrosis in the mucosa in consequence of the lodgment in it of pathogenic streptococci. These organisms appear to reach the stomach or duodenum by the blood stream, either being swallowed or entering the blood from a focus of sepsis in the teeth, tonsils, appendix, gall-bladder, or some other source. According to Rosenow, the ulcer-forming organisms exhibit an "elective" affinity for the gastric mucous membrane while others may show a similar affinity for, say, the gall-bladder. Be this as it may, the result of the formation of an area of necrosis in the mucous membrane is that auto-digestion of the dead tissue takes place and a small acute ulcer forms. Most of these heal quickly, but in certain circumstances—for example abnormally high gastric acidity—one of them fails to heal, gradually enlarges, and becomes a chronic ulcer. The remaining organic affection of the stomach (*gastritis*) is of less frequent occurrence than was formerly supposed.

The functional disorders of the stomach which are responsible for a great deal of what is commonly called "dyspepsia" are still but ill-understood although, by means of X-ray examinations and the use of "fractional" test meals, light is gradually being thrown upon them. Two chief types of functional disorder occur, secretory and motor, and each of these may be affected in the direction either of excess or defect.

Secretory Disorders.—It is now known that the gastric juice as secreted has an acidity of about 0.5%, but that this is reduced to the optimum acidity for digestion (0.2%) by dilution and neutralization in the stomach, and that the most powerful factor in neutralization is the regurgitation of duodenal contents through the pylorus. An excessive acidity of the stomach contents therefore ("*acid dyspepsia*," *hyperchlorhydria*) may be due either to over-production of gastric juice or to deficiency of neutralization, or to both, and can no longer be regarded as a definite "clinical entity." Deficient acidity on the other hand (*hypochlorhydria*, *achylia*) may be due either to defective secretion or to excessive neutralization. The secretion of gastric juice is controlled partly by the vagus nerve and partly by chemical hormones, and may therefore be affected either by variations in the excitability of the nervous system or by the quality of the food. Excess of secretion is perhaps commoner in men, defect is more often found in women, but over-acidity is more prone to cause symptoms than under-acidity.

Motor Disorders.—These are of greater importance as a cause of dyspepsia than disorders of secretion. The stomach has two motor functions (*peristalsis* and "tone") and these may be disordered independently. Both are much under nervous influence, the vagus increasing tone and peristalsis, while the sympathetic has an opposite effect. Diminution of tone (*hypo-motility*, *atony*) is a commoner cause of symptoms than excess and is specially apt to occur in women. Emotional disturbances are prone to bring it about. Excess of tone and peristalsis are often associated with over-acidity, whereas deficiency of tone and acidity often, though by no means always, coincide.

The symptoms of the functional disorders of the stomach differ notably from those of the more serious organic diseases. Pain, vomiting and wasting are absent, and the patient's chief complaints are of discomfort, flatulence, acidity, and so forth. As disorder of function is largely nervous in origin, treatment must be directed in great measure to the central nervous system, but acidity can be corrected by antacids, atony by strychnine, and so on. The diet of the patient must also be adapted to the weakened organ.

The Colon.—The investigation of diseases of the colon has been facilitated by the introduction of the methods of examination by the X-rays after an opaque enema and by the sigmoidoscope. Cancer is still the most serious affection, the sigmoid and pelvic colon being its commonest sites. Treatment is by operation and, if undertaken early enough, is often successful. Ulceration of the colon is now divided into (a) dysenteric and (b) non-dysenteric. Dysenteric ulceration (*see* DYSENTERY) may

be caused either by the amoeba histolytica or by dysenteric bacilli of the Shiga or Flexner type. The distinction between these different forms can be made by a bacteriological examination of the stools and by the serum agglutination test. Non-dysenteric ulceration (*ulcerative colitis*) is not very uncommon as a primary disease in Great Britain. Its symptoms are the same as those of the dysenteric variety (diarrhoea with the passage of blood and mucus, some fever, pain and tenesmus) and it can be recognized by the use of the sigmoidoscope. Nothing is yet definitely known of its bacteriology. Antidysenteric serum is a powerful aid in the treatment of acute bacillary dysentery while emetine is a specific for the amoebic form. Non-dysenteric ulceration is treated by lavage and, in severe cases, by the operation of appendicostomy.

The frequent occurrence of little pouches (*diverticula*) in the wall of the colon has been established by modern methods of investigation. Sometimes these become inflamed when the condition termed "diverticulitis" arises. It is not without danger. Much attention has been devoted in recent years to the alleged stagnation of the contents of the large bowel (colon stasis) with consequent absorption of poisons into the blood (auto-intoxication). Such stagnation is believed to be promoted by dropping or displacement of the colon or by the undue mobility of sections of it, and extensive operations have been undertaken for the correction of these conditions. While, however, auto-intoxication may sometimes take place, it is beginning to be realized that it is not nearly so frequent as was supposed and that operation for it is rarely necessary or advisable.

The Pancreas.—The pancreas is still very largely the *terra incognita* of the abdomen, mainly on account of its inaccessible position. The introduction of tests for "pancreatic efficiency," however, has helped to make the diagnosis of its diseases easier. Amongst these tests are Loewe's adrenalin mydriasis reaction, the urinary diastase test, and the estimation of the unsplit fat in the stools. Glycosuria, also, is often an indication of the failure of the internal secretion (insulin).

New-growth (cancer) is the most serious disease of the pancreas and one of the commonest. It specially affects the head of the organ and usually shows its presence by the production of obstructive jaundice.

Acute pancreatitis (haemorrhagic necrosis of the pancreas) is one of the conditions which produce what is termed an "abdominal catastrophe." It is difficult of diagnosis and is only curable by laparotomy.

Chronic pancreatitis, an interstitial inflammation or fibrosis of the organ, may result from partial obstruction of the duct, e.g., by gall-stones, or from an ascending infection of it. The symptoms are very much the same as those produced by cancer.

The Liver.—Recent work has thrown a good deal of light on the nature of jaundice. It is now known that bile pigment is not produced in the liver cells but is derived from the breaking down of red blood corpuscles in the "reticulo-endothelial system"—a network of cells widely diffused in the body but especially in the spleen. The pigment so produced is picked out of the blood by the hepatic cells and transferred to the bile. Two chief varieties of jaundice are recognized: (a) obstructive, (b) non-obstructive. The former is due to any gross obstruction in the bile ducts such as may be caused by cancers or other tumours pressing upon or involving the ducts, impacted gall-stone and so forth. It is characterized by the complete absence of bile from the stools and its presence in the urine.

Non-obstructive jaundice, as it is usually called, is of two varieties—the haemolytic and the toxic. The former is due to increased destruction of red blood corpuscles and occurs to some extent in Addisonian (pernicious) anaemia and also in the rare disease known as "family jaundice"; toxic jaundice on the other hand is brought about by severe damage to the liver cells rendering them incapable of transferring bile pigment from the blood to the bile. Many poisons act on the cells in this way, such as arsenic and phosphorus, as well as the toxins of certain organisms, e.g., those of yellow fever and some septic infections; poisons of "endogenous" origin may act similarly, as in acute

yellow atrophy of the liver and the toxic jaundice of pregnancy. In all forms of non-obstructive jaundice bile is present in the stools but it may or may not be present in the urine. So-called "catarrhal jaundice," formerly believed to be obstructive, is now, largely as a result of the van den Bergh test, known to be due, in part at least, to direct damage of the liver cells, although obstruction of the ducts from catarrh also plays a part in its production. Much work has recently been done on the pathology of gall-stone formation. It is generally agreed that infection of the gall-bladder is a predisposing factor, the infection being usually conveyed through the blood stream in the same way as in cases of peptic ulcer. In addition it is possible that an excess of cholesterol in the blood contributes to their formation. For the other chief diseases of the liver, cancer and cirrhosis, see LIVER, DISEASES OF.

Bassler, *Diseases of the Stomach and Upper Alimentary Tract* (6th ed. 1926), and *Diseases of the Intestines and Lower Alimentary Tract* (1920); T. I. Bennett, *The Stomach and Upper Alimentary Canal in Health and Disease* (London, 1925); R. D. Carman, *The Röntgen Diagnosis of Diseases of the Alimentary Canal* (Philadelphia, 2nd ed. 1920).

ALIMONY, in law the allowance for maintenance to which a wife is entitled out of her husband's estate for her support in or consequent upon a matrimonial cause. Though, as a rule, payable to a wife, it may, if the circumstances of the case warrant it, be payable by the wife to the husband. Alimony is of two kinds, (a) temporary (*pendente lite*), and (b) permanent. Temporary alimony, or alimony pending suit, is the provision made by the husband for the wife in causes between them to support her during the progress of the suit, and is allowed whether the suit is by or against the husband and whatever the nature of the suit may be. The usual English practice is to allot as temporary alimony about one-fifth of the husband's net income; where it appears that the husband has no means or is in insolvent circumstances, the court will refuse to allot temporary alimony. So where the wife is supporting herself by her own earnings, this fact will be taken into consideration. And where the wife and husband have lived apart for many years before the institution of the suit, and she has supported herself during the separation, no alimony will be allotted. Nor will the wife be entitled to alimony where she has sufficient means of support independent of her husband. *Permanent* alimony is that which is allotted to the wife after final decree. By the Matrimonial Causes Act, 1907, the court may, if it think fit, on any decree for dissolution or nullity of marriage, order that the husband shall, to the satisfaction of the court, secure to the wife such a gross sum of money or such annual sum of money for any term not exceeding her life, as having regard to her fortune (if any), to the ability of her husband, and to the conduct of the parties, it may deem reasonable. The court may suspend the pronouncing of its decree until a proper deed or instrument has been executed by all necessary parties. The court may also make an order on the husband for payment to the wife during their joint lives of a reasonable monthly or weekly sum for her maintenance; the court may also at any time discharge, modify, suspend or increase the order according to the altered means of the husband; the court has also power to make provision for children. Alimony is paid direct to the wife or to a trustee or trustees on her behalf, but the court may impose any restrictions which seem expedient. We may also describe as a kind of alimony the allowance of a reasonable weekly sum not exceeding £2 which in England, under the Summary Jurisdiction (Married Women) Act, 1895, may be given to a married woman on applying to a court of summary jurisdiction if she has been forced by cruelty to leave her husband or has been deserted by him.

United States.—Alimony is granted on much the same principle as in England, though in many states the courts of equity as such may grant alimony without divorce or separation proceedings independently of any statute, on the ground that the husband ought to support his wife when she lives apart from him for his fault, and since the courts of common law provide no remedy the courts of equity will. This is so in Alabama, Kentucky, North Carolina, Iowa, California, Ohio, Virginia, South Dakota and the

District of Columbia. In other states alimony without such proceedings is allowed by statute, and such alimony is now very general throughout the United States. The usual grounds for the allowance of it are desertion and such conduct as would amount to legal cruelty. After divorce *a vinculo*, alimony or separate maintenance is sometimes granted on good reason. In several states alimony or maintenance is by statute allowed to the husband in certain cases out of the wife's property. This is so in Massachusetts, Virginia, Rhode Island and Iowa. In Oregon he is entitled to one-third of his wife's real estate in addition to maintenance on divorce for her fault. Judgment for alimony is considered a judgment *in personam* and not *in rem*, and can only be enforced outside the state where rendered in case the husband has been personally served with process within that state.

ALIN, OSCAR JOSEF (1846–1900), Swedish historian and politician, was born at Falun Dec. 22, 1846, and became rector of Uppsala university.

Among his numerous works the following are specially worthy of note: *Bidrag till svenska rådets historia under medeltiden* (1872); *Sveriges Historia, 1511–1611* (1878); *Bidrag till svenska statsrättens historia* (1884–87); *Den svensk-norsk Unionen* (1889–91), the best book on the Norweco-Swedish union question from the Swedish point of view; *Fjerde Artiklen af Fredstraktaten i Kiel* (1899); *Carl Johan och Sveriges yttre politik, 1810–1815* (1899); *Carl XIV. och Rikets Ständer, 1840–1841* (1893). He also edited *Svenska Riksdagsakter, 1521–1554* (1887), in conjunction with E. Hildebrand, and *Sveriges Grundlagar* (1892).

ALINGTON, CYRIL ARGENTINE (1872–), British educationist and writer, was born in Ipswich, Oct. 22 1872, and educated at Marlborough College and Trinity College, Oxford. In 1908 he was appointed headmaster of Shrewsbury School and in 1916 succeeded his brother-in-law, Edward Lyttelton, as headmaster of Eton. Dr. Alington commanded the respect and affection of his pupils and while not hostile to new ideas sought to maintain rather than modify the public school tradition. His published works include *A Schoolmaster's Apology* (1914); *Doubts and Difficulties* (1929); two popular novels, *Strained Relations* (1922) and *Mr. Evans* (1922); some humorous verse, and collections of sermons and addresses.

ALIUOT PART, an exact divisor of a number or quantity (that is, a divisor giving an integral quotient). For example, 2 is an aliquot part of 10, $3\frac{1}{3}$ is an aliquot part of 100, a line $2\frac{1}{2}$ in. long is an aliquot part of one that is $7\frac{1}{2}$ in. long, and $\frac{1}{3}$ is an aliquot part of 1; but $\frac{2}{3}$ is not an aliquot part of 1, the quotient of 1 divided by $\frac{2}{3}$ not being an integer.

ALIRAJPUR, an Indian State under the Bhopawar agency in central India. It lies in Malwa, near the frontier of Bombay. It has an area of 836sq.m.; and a pop. (1921) of 89,364. The country is hilly, and many of the inhabitants are aboriginal Bhils.

ALISMACEAE, in botany, a family of monocotyledons belonging to the series Helobieae, and represented in Britain by the water plantain, *Alisma Plantago*, the arrow-head, *Sagittaria*, the

A VERTICAL SECTION THROUGH THE FLOWERING RUSH AND ITS FLORAL DIAGRAM

star-fruit, *Damasonium*, and flowering rush, *Butomus*. They are marsh or water-plants with generally a stout stem (*rhizome*) creeping in the mud, radical leaves and a large, much branched inflorescence. The submerged leaves are long and grass-like, the floating leaves oblong or rounded, while the aerial leaves are borne on long, thin stalks above the water, and are often arrow-shaped at the base. The flower-bearing stem is tall; the flowers are borne in whorls on the axis as in arrow-head, on whorled branchlets as in water plantain or in an umbel as in *Butomus* (see fig.). They are regular and rather showy, generally with three greenish sepals, followed in regular succession by three white or purplish petals, six to indefinite stamens and six to indefinite free carpels. The fruit is a head of achenes or follicles. The flowers contain honey, and attract flies or other small insects by which pollination is

effected. There are about 75 species in eleven genera, widely distributed in temperate and warm zones. *Alisma Plantago* (see fig.), a common plant in Britain (except in the north) in ditches and edges of streams, is widely distributed in the north temperate zone and on mountains.

In the United States and Canada the family is represented by about 40 native species, some three-fourths of which are arrow-heads. Among the other representatives are the cosmopolitan water plantain, two species of bur-head (*Echinodorus*), the dwarf bur-head (*Helianthium parvulum*) and the fringed water plantain or star-fruit (*Damasonium californicum*) of California. (See ARROW-HEAD.)

ALISON, SIR ARCHIBALD, BART. (1792-1867), Scottish historian, was born at Kenley, Shropshire, England. His father, ARCHIBALD ALISON (1757-1839), was the author of a well-known book of *Essays on the Nature and Principles of Taste* (1790). The son was educated at Edinburgh university and held various high legal positions in Scotland. He spent fifteen years in collecting the materials for his *History of Europe*.

The history of the period from the beginning of the French Revolution till the restoration of the Bourbons in 1815 was completed in ten volumes in 1842. Within a few years it ran through ten editions, and was translated into many of the languages of Europe, as well as into Arabic and Hindustani. It brought together, though not always in a well-arranged form, an immense amount of information that had before been practically inaccessible to the general public. A continuation of the *History*, embracing the period from 1815 to 1852, which was completed in four volumes in 1856, did not meet with the same success as the earlier work. His literary activity continued till within a short time of his death, the chief works he published in addition to his *History* being the *Principles of Population* (1840), in answer to Malthus; a *Life of Marlborough* (1847, 2nd edition, greatly enlarged, 1852); and the *Lives of Lord Castlereagh and Sir C. Stewart* (1861). Three volumes of Alison's political, historical and miscellaneous essays were reprinted in 1850. His autobiography, *Some Account of My Life and Writings*, edited by his daughter-in-law, Lady Alison, was published in 1883 at Edinburgh. His elder son, SIR ARCHIBALD ALISON (1826-1907), was a distinguished soldier who served in the Crimea and the Indian Mutiny, was second in command of the Ashanti expedition (1873-74), and led the Highland Brigade at Tel-el-Kebir. He was made full general in 1887, and became military member of the Council of India in 1889.

ALI WAL, a village in British India, Ludhiana district, Punjab, on the left bank of the Sutlej, famous as the scene of a great battle of the first Sikh War (*q.v.*). In Jan. 1846 it was held by a Sikh army, which had crossed the river and threatened Ludhiana. On the 28th Sir Harry Smith attacked, and after a desperate struggle pushed the enemy into the river, where large numbers perished, leaving 67 guns to the victors.

ALI WAL NORTH, a town situated on the left bank of the Orange river, which here forms the boundary between the Cape Province and the Orange Free State, and which is spanned by a bridge 860ft. in length; 30° 31' S., 26° 53' E. Pop. (1921) white 2,443, coloured 3,819. Altitude 4,350ft.; distance by rail from East London, 280 miles. Aliwal North is a trading centre for the surrounding country and for south-west Basutoland. It is also the administrative centre for the magisterial district of the same

THE WATER PLANTAIN, THE COMMON REPRESENTATIVE OF THE ALISMACEAE FAMILY IN GREAT BRITAIN. Upper left, the flower enlarged. Upper right, its floral diagram. Lower left, vertical section through flower. Lower right, the fruit

name. The town was founded in 1849 and is laid out on the usual South African rectangular plan. The streets are bordered by open water-furrows, and lined with trees. A dam, built across the Orange river, has made available for boating a six mile stretch of water, which provides the town with electric light.

Aliwal North is becoming recognized as one of the chief inland health resorts of South Africa. The climate is recommended for sufferers from lung troubles. The average relative humidity for the year is 61.5 and the average cloudiness 3.3. The temperature may rise to over 90° in summer, but the nights are cool, and in winter sharp frosts occur. A little over a mile from the town are high-temperature mineral springs yielding over a million gal. a day. The water is beneficial for rheumatism and skin diseases. A gallon contains 0.85 grains of lithium carbonate, 7.41 carbonate of lime, 1.95 sulphate of magnesium, 3.24 ammonia, 0.95 potash, 8.10 calcium chloride, 61.35 sodium chloride, 1.04 silica, 0.12 sodium bromide, 5.22 carbonic acid gas. At the springs, baths have been built, and 14ac. of pleasure grounds have been laid out.

The town was named in honour of Sir Harry Smith, governor of Cape Colony (1847-52), to commemorate the victory of Aliwal.

ALIZARIN, a vegetable dyestuff prepared from the root of the madder (*Rubia tinctorum*), was known to the ancients, and was prepared entirely from this source until 1868. The pure substance crystallizes in red prisms melting at 290° C. It is insoluble in water, and not very soluble in alcohol. It dissolves readily in caustic alkalis on account of its phenolic character, and it forms a yellow-coloured di-acetate. Its value as a dyestuff depends on its power of forming insoluble compounds (lakes) with metallic oxides. It is in the form of these lakes that it produces coloured effects on textile fibres. Alizarin red on wool is a complex lake of alizarin with the oxides of calcium and aluminium (see DYEING).

Madder contains a glucoside (*q.v.*), ruberythric acid, which is readily broken up (hydrolysed) by acids or ferments into alizarin and glucose:

Alizarin has the chemical constitution 1.2 Dihydroxyanthraquinone and the structural formula

It owes its phenolic properties to the two —OH (hydroxy) groups attached to a benzene nucleus.

The first step in the synthetical production of alizarin was the discovery in 1868 of C. Graebe and C. Liebermann that on heating with zinc dust, alizarin was converted into anthracene, an aromatic hydrocarbon obtained from coal tar. They then oxidized anthracene to anthraquinone and brominated the quinone. The dibrominated product so obtained was fused with caustic potash, the melt dissolved in water, and on the addition of hydrochloric acid to the solution, alizarin was precipitated. This process, owing to its expensive nature, was soon superseded by another, discovered simultaneously by the above-named chemists and by Sir W. H. Perkin, the method being to sulphonate anthraquinone, and then to convert the sulphonic acid into its sodium salt and fuse this with caustic soda. Alizarin is also synthesised by heating catechol with phthalic anhydride and sulphuric acid at 150° C.

ALKAHEST (a pseudo-Arabic word believed to have been invented by Paracelsus), a liquid having the power of dissolving gold and every other substance, much sought after by the alchemists, who supposed it would possess invaluable medicinal qualities.

ALKALI, an Arabic term originally applied to the ashes of plants, from which by lixiviation carbonate of soda was obtained in the case of sea-plants and carbonate of potash in that of land-plants. The method of making these "mild" alkalis into "caustic"

alkalis by treatment with lime was practised in the time of Pliny in connection with the manufacture of soap, and it was also known that the ashes of shore-plants yielded a hard soap and those of land-plants a soft one. But the two substances were generally confounded as "fixed alkali" (carbonate of ammonia being "volatile alkali"), till Duhamel du Monceau in 1736 established the fact that common salt and the ashes of sea-plants contain the same base as is found in natural deposits of soda salts ("mineral alkali"), and that this body is different from the "vegetable alkali" obtained by incinerating land-plants or wood (pot-ashes). Later, Martin Heinrich Klaproth, finding vegetable alkali in certain minerals, such as leucite, proposed to distinguish it as potash, and at the same time assigned to the mineral alkali the name *natron*, which survives in the symbol, Na, now used for sodium. The word alkali supplied the symbol for potassium, K (*kalium*). In modern chemistry alkali is a general term used for compounds which have the property of neutralizing acids, and is applied more particularly to the highly soluble hydroxides of sodium and potassium, and of the three rarer "alkali metals," caesium, rubidium and lithium, also to aqueous ammonia. In a smaller degree these alkaline properties are shared by the less soluble hydroxides of the "metals of the alkaline earths," calcium, barium and strontium, and by thalious hydroxide. An alkali is distinguished from an acid or neutral substance by its action on litmus, turmeric and other indicators. (See ALKALI MANUFACTURE.)

ALKALI MANUFACTURE. The group of materials includes sodium carbonate (soda ash), caustic soda, bicarbonate of soda, soda crystals (washing soda), sodium silicate (water-glass), sulphate of soda (salt cake) and sodium sulphide. Certain other substances are linked with these in manufacture, such as chlorine, which is produced simultaneously with caustic soda by certain processes, and which in turn gives rise to bleaching powder, hydrochloric acid and so forth. Alkali and chlorine are, under modern practice, inseparable, and form one comprehensive and intimately connected group of manufactures (the "heavy chemical" trade). The principal products (soda ash, caustic soda and chlorine) form raw materials for other industries.

The chief centres of alkali production are England, Belgium, France, Germany and the United States.

MANUFACTURE OF SODIUM CARBONATE

The manufacture of alkali and chlorine by modern methods requires complicated plant; but the relatively few plants in operation are highly efficient and, economically placed as regards carriage of raw materials and shipping of products, and work on a very large scale. It is to be emphasized that the industry has

FIG. 1.—DIAGRAM OF A LIME KILN. The mixture is discharged from the hopper at the top at intervals. The charge immediately below spreads the charge evenly. The carbon dioxide is drawn off through the vent shown, and the lime is withdrawn at the bottom. Kilns vary in size, some being 70 ft. high with internal diameter of 14 feet.

Raw Materials.—The raw materials required are coal (to supply power and heat), salt and limestone of good quality. Salt

is the source of the sodium in the finished products. It occurs as a mineral, widely distributed over the globe, in subterranean beds of great thickness. For the purpose of alkali manufacture it is not mined, but extracted in the form of brine by pumping. This brine occurs naturally in many places and has been formed by the percolation of underground springs through the salt beds; when of a sufficient degree of saturation it is used direct. In other cases water has to be admitted artificially to the salt deposits and then, after saturation, pumped again as brine.

The limestone serves a double purpose; it is the source of the carbon dioxide gas which when combined with the sodium of the

salt produces sodium bicarbonate; and it is also the source of the lime with which, as we shall see presently, the ammonia (from which the process takes its name) is recovered and returned to the cycle of operations. Only the better class of limestone is used for alkali. The stone is quarried and crushed; it is then burnt, intimately mixed with coke, in tall kilns to which a regulated quantity of air is admitted (see fig. 1). These kilns are periodically charged at the top; and as the charge travels downwards the lime is extracted at the bottom and the kiln gases containing the carbon dioxide, are drawn off at the top. Ammonia, which forms the key to the whole operation and is obtained principally from gas-works liquor (a residue from the distillation of coal), cannot properly be regarded as a raw material.

FIG. 2.—SECTION OF PART OF AN AMMONIA ABSORPTION TOWER. The gas enters each compartment through funnel shaped holes which are surmounted by domes to distribute the gas evenly into the liquor. The liquor descends through the pipes, comes in contact with the gas, absorbs part of it and leaves the compartment.

The Process.—The production of crude sodium bicarbonate is the central operation. The brine, usually after purification to remove undesirable magnesium and calcium compounds, is pumped

into the top of tall vertical iron absorption towers. Simultaneously ammonia gas and some carbon dioxide are pumped in at the bottom. The thorough contact of the falling brine and the rising gases is ensured by the internal partitioning of the vessel in such a way that the whole of the ammonia is absorbed (see fig. 2). This absorption gives rise to a considerable evolution of heat, so the ammoniated brine is passed through a series of coolers to reduce its temperature.

From the coolers the liquor is pumped to the top of a system of iron towers, subdivided internally, at the bottom of which carbon dioxide gas enters; this carbon dioxide is obtained partly from the limekilns as already described and partly from a later stage of the process in which sodium bicarbonate is heated to form the carbonate. The inter-

FIG. 3.—PART OF AN AMMONIA-SODA PRECIPITATING TOWER. The gas rises from the bottom through holes in the partitioning plates. Each hole is surmounted by a flat dome. The liquor descends and the contact with the gas produces sufficient agitation to enable the bicarbonate so formed to be carried to the bottom with the liquor.

action of this carbon dioxide with the ammoniated brine produces a precipitate of sodium bicarbonate and at the same time disengages a considerable quantity of heat which has to be counteracted by a system of coolers in the lower part of the towers; the reaction is reversible, and is greatly influenced by the temperature, so that the maintenance of the liquor at the correct temperature is of the first importance (see fig. 3).

The magma of bicarbonate and mother liquor is taken con-

tinuously from the towers and fed on to rotary vacuum filters (see fig. 4). Here the mother liquor is removed and the bicarbonate washed with a little water. The crude bicarbonate is then conveyed automatically to the so-called "finishing machines" for conversion to carbonate. These machines consist of hemi-cylindrical iron vessels, with mechanical agitators, and are heated from below either with producer gas or by direct coal-firing. The crude bicarbonate is fed in at one end, and in its passage along the length of the machine loses carbon dioxide, water, and any ammonia

FIG. 4.—ILLUSTRATING THE PRINCIPLE OF THE ROTARY FILTER
The perforated iron drum revolves continuously and is so arranged that a partial vacuum exists within it. As the drum turns the vacuum sucks in the liquor through the cloth layer and leaves a layer of solids upon it. The scraper removes this layer from the drum, leaving the cloth clean for the next revolution

that it may contain. These gases are then returned to the towers. The product issuing from the finishing machines is sodium carbonate, and is usually referred to as "soda ash." The purity is very high, averaging 98% sodium carbonate, the remainder being mostly salt.

Uses of Soda Ash.—Almost every manufactured commodity has at some stage of its production made use of soda ash or its derivatives, the yearly world production of which has now reached some three and a half millions of tons. For example, glass of all kinds contains from 10 to 20% by weight of soda and accounts for roughly one quarter of the total consumption. There are indeed certain qualities of glass which do not use soda ash, but these are for special use and do not affect the general statement. All hard soap has been made primarily from animal or vegetable fats and caustic soda, the latter being derived directly from soda ash; this accounts for another quarter of the consumption. The textile industry accounts for one-sixth, employed in wool-scouring, cotton-scouring, calico printing, flax boiling and so on. The general chemical industry takes about one-tenth, and paper one-twentieth. The remainder is consumed in comparatively small quantities by a number of industries, a full list of which is astonishing in its length and variety. Fig. 5 gives this distribution, which is of course only approximate, in a graphic form.

Recovery of Ammonia.—Apart from the small amount carried forward with the crude bicarbonate, which is recovered separate, the bulk of the ammonia is contained in the mother liquor separated at the filters and is in the form of ammonium chloride. This liquor is therefore distilled with lime. As, however, the liquor still contains some ammonia in combination with residual carbon dioxide it is first of all subjected to treatment with steam to eliminate these compounds.

The liquor is then fed, together with milk of lime produced by mixing lime from the kilns with water, into the top of the distiller, a tall iron tower with internal divisions: exhaust steam is admitted to the bottom, the temperature of the liquor is raised, and the ammonia distills off accompanied by some carbon dioxide.

FIG. 5.—APPROXIMATE DISTRIBUTION OF SODA ASH

Almost every manufactured commodity needs soda-ash or its derivatives in its production. The annual world requirements now reach 3½ million tons

These gases together with those given off in the preliminary steam treatment are cooled and then pass to the absorption system to undergo a further round of the process. Under modern methods the loss of ammonia is extremely small. The liquor leaving the bottom of the distiller contains calcium chloride and about one-third of the salt that originally entered the process: some calcium chloride is occasionally extracted and sold, but in general it is a waste product. It also contains excess lime, grit and pebbles, the economical disposal of which is a problem still to be solved. Fig. 6 is a diagram that will serve to connect in the reader's mind the foregoing operations with some of those about to be described.

Sodium Bicarbonate.—Part of the crude bicarbonate obtained by the ammonia soda process is converted into "refined

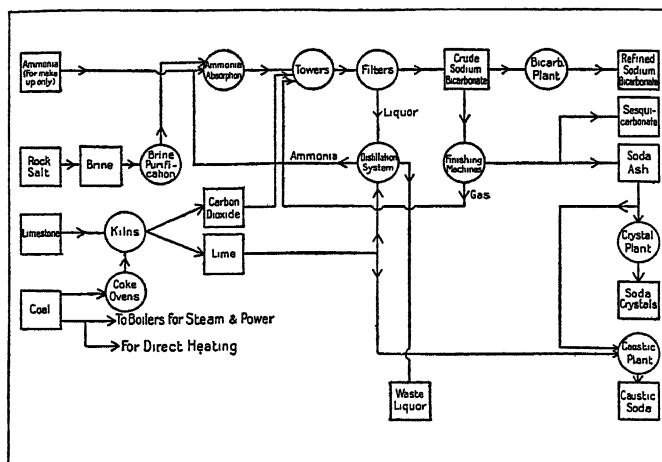

FIG. 6.—THE AMMONIA-SODA PROCESS AND PRINCIPAL PRODUCTS
The raw materials used are shown to the left. The plant and the processes are shown in continuous progression across the diagram. The resulting products are to be seen on the right

bicarbonate of soda" which is largely used in the preparation of food and drugs. The trade in it is very steady, and does not vary appreciably from year to year. It is principally used as a source of carbon dioxide gas for the manufacture of artificial mineral waters. Another source of consumption is the baking industry: baking powders contain sodium bicarbonate and a weak vegetable acid (citric, tartaric, etc.) which are prevented from reacting on one another when dry by a film or glaze of starch round the individual grains: on moistening in the process of dough making, these compounds react, carbon dioxide is evolved, and the dough "rises." The action of yeast is similar in that carbon dioxide is produced but dissimilar in that the production of the gas is due to organic fermentation. Bicarbonate of soda is also used largely in medicine and in proprietary compounds for daily use. It is one of the principal ingredients of "blue" for laundry purposes, and a large amount is consumed in the manufacture of dry soap.

Sodium Sesquicarbonate.—This is the form in which soda occurs in nature, mixed of course with more or less impurity. In composition it is intermediate between sodium carbonate and bicarbonate, and it contains some combined water:—

It is manufactured directly from crude bicarbonate, the process of heating to drive off carbon dioxide not being carried so far as for the manufacture of soda ash. It has the advantage of being a mild alkali well suited for laundry detergent purposes and is sometimes known as "concentrated soda crystals."

Soda Crystals (Washing Soda).—If soda ash be dissolved in water and the solution allowed to crystallize slowly, large transparent crystals are produced of the composition $\text{Na}_2\text{CO}_3 \cdot 10\text{H}_2\text{O}$. In this form the product is familiar to everyone as "washing soda." In practice the manufacture is not quite so simple. Soda ash is first dissolved in hot water. This solution frequently contains small amounts of iron and organic matter which are removed and the liquor is rendered colourless by the addition of small quantities

of bleaching powder. The clear settled liquor is then transferred to large steel crystallizing pans; where it gradually cools and deposits the crystals. After a few days these are fished out, dried, graded for size and packed. Their principal use is in domestic and laundry work, in the manufacture of dyestuffs, varnishes and photographic materials, and in tanning.

Sodium Silicate (Water-glass).—This familiar product is manufactured by fusing together soda ash and clean pure sand in a furnace. The latter is built of fireclay blocks with an arched roof of silica, and is heated internally by a direct flame produced by the combustion of producer gas or oil. The mixed charge of ash and sand is fed in at one end of the furnace and the molten glass is drawn off at intervals at the other. The glass may either be broken up by jets of water as it runs in a molten stream from the furnace, or it may be allowed to cool and be subsequently broken up by hand. It is then fed into a dissolver which may be either of a horizontal and rotary type, or stationary and vertical. In either case the glass is treated with a mixture of water and steam and goes into solution. The latter is then bleached, if necessary, and clarified; and is then concentrated in evaporators of modern type. The resultant viscous fluid is the "water-glass" of commerce. A familiar but minor use is that of preserving eggs; the effect is produced by the closing of the pores of the egg shell by the silicate, which results in the exclusion of air and the prevention of putrefaction. It is an excellent adhesive for all purposes and particularly for machine work in box making. In the United States particularly this application has become very widespread. It is used with remarkable effect to harden and consolidate the surface of concrete: the effect is produced by the interaction of the silicate with the lime of the concrete whereby hard calcium silicate is formed. The silicate may be applied either during the process of concrete making or to the finished concrete surface. It often forms an ingredient of soap of inferior quality. Other applications include the lining of casks, ceramics, fireproofing of wood, preservation of wood against the attacks of insects, ink making, flotation of ores, paints, silk weighting, and so on. For all these various uses there is usually available a particular grade of silicate, dependent upon the ratio of silica to soda best suited to the purpose, the degree of viscosity required and the rate of drying.

MANUFACTURE OF CAUSTIC SODA

Caustic soda can be produced in two separate ways by the conversion of soda ash direct, or by subjecting brine to the action of the electric current (electrolysis) whereby caustic soda is produced simultaneously with chlorine. Two methods may be used for the direct conversion of soda ash, that of Löwig, a now obsolete process, and the lime-caustic process.

The Lime-Caustic Process.—In this process a solution of soda ash is treated with lime, either in the form of milk of lime or by direct introduction of quicklime. The ensuing reaction causes a "double decomposition" to take place, which produces a solution of caustic soda and a precipitate of calcium carbonate.

This reaction does not proceed to completion at once nor does the precipitate settle readily; so that a large part of the plant, after the reaction vessel, consists of time vessels and settling vats. After the liquor has passed through these, and the residual calcium carbonate has been filtered out, it passes to a series of vacuum evaporators, working usually in two or three stages, where it is concentrated by steam heat to a degree that is limited by the economics of the method. The final stage of the concentration, which results in the complete elimination of all water, is accomplished in large hemispherical iron pots heated underneath by direct firing by coal or producer gas. The final product is molten caustic soda which is run or ladled off into thin iron drums where it solidifies (see fig. 7).

As the conversion of soda ash can never be taken to absolute completion whatever method be employed (the reaction being a "balanced" or "reversible" one), means must be found for the

removal of unchanged ash and impurities. These "salts" separate out in the earlier stages of the concentration of the liquor. The precipitated calcium carbonate (chalk) may either be sold, after drying, for agricultural use, or may be calcined and returned to the first stage of the process.

The Electrolytic Process.—This method is entirely different and depends upon the effect produced when a current of electricity is passed through brine. This is more particularly described

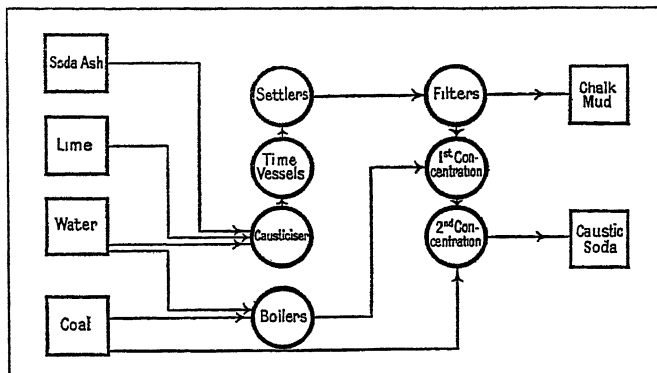

FIG. 7.—THE MANUFACTURE OF CAUSTIC SODA FROM SODA-ASH
The raw materials are shown on the left. The lines show the flow of materials through the various processes, with the finished products on the right

under the heading CHLORINE IN INDUSTRY (*q.v.*). The effect, in short, is to produce simultaneously a solution of caustic soda, chlorine gas, and hydrogen gas. The caustic solution is treated as already described; the chlorine is piped off to subsidiary plants; while the hydrogen may either be allowed to escape into the air or may be converted to ammonia or hydrochloric acid. This method is finding increased application and the caustic soda now made by it forms an appreciable proportion of the total: at the same time it is evident that the output is limited by the extent to which it may be found possible to dispose of the concomitant chlorine.

Uses of Caustic Soda.—An important consumer of caustic soda is the artificial silk trade which uses it for digesting and purifying the cellulose which forms the basis of the industry. One-third or more of the total output of caustic soda is used for this purpose, no account being taken of the caustic soda made by soapmakers themselves. The largest consumer of caustic soda is the soap industry, in which the caustic is used to decompose the animal and vegetable fats, with liberation of glycerine and production

FIG. 8.—APPROXIMATE DISTRIBUTION OF CAUSTIC SODA

Caustic soda is the second most important product in the alkali industry. The two largest consumers are the soap and artificial silk industries

of the sodium salt of the acid of the fat; this sodium salt is in fact soap of the "hard" variety. "Soft" soaps contain potash in place of soda. The textile industry uses caustic soda for a variety of purposes, one of the more familiar being the process of "mercerization" by which cotton fibre can be made to take on a gloss somewhat resembling silk. Soap and textiles account each for about one-sixth of the total consumption; and paper and oil refining for about one-eighth combined. The remainder is split up among a very large number of minor uses. Fig. 8 gives a graphic representation of these proportions, which, as for soda ash, are necessarily only approximate.

MANUFACTURE OF SALT CAKE

By this name is known the residue resulting from the treatment of salt with strong sulphuric acid in the manufacture of hydrochloric acid (*q.v.*). It consists of sodium sulphate with a small proportion of free sulphuric acid. Apart from the strictly utilita-

rian view, this product has an interest inasmuch as its manufacture, together with that of sodium sulphide, is the only surviving part of the celebrated Le Blanc soda process (*see* LE BLANC, NICOLAS).

In brief, the process consists of two parts, the salt-cake process, and the "black ash" process. The salt-cake process is described elsewhere (*see* HYDROCHLORIC ACID); the reaction of sulphuric acid with common salt produces hydrochloric acid and sodium sulphate (salt cake).

The second stage involves the conversion of the salt cake to carbonate by heating with limestone and coal; the former to provide the required carbonic acid and the latter to reduce the salt cake to a form in which it will react with the limestone: thus:—

The mass (black ash) resulting from this furnace operation was then, after standing for a day or two, extracted with water and the liquor evaporated for the recovery of sodium carbonate. The insoluble part of the black ash formed unsightly heaps of "alkali waste" upon which much research had to be conducted before a satisfactory method of utilizing their valuable sulphur contents was discovered. Salt cake itself is a white powder and usually contains a small proportion, about 1%, of free sulphuric acid, with a smaller amount of undecomposed salt.

When the Le Blanc process was the principal source of alkali, salt cake was required in such quantity that the hydrochloric acid produced with it was more than could be absorbed in industry, so that processes were devised by Weldon and Deacon for converting a large proportion to chlorine for subsequent use in the manufacture of bleaching powder. The introduction of the ammonia soda process has completely reversed that state of affairs. Although a certain quantity of salt cake is still required, for purposes specified below, the hydrochloric acid thereby produced does not suffice for modern requirements; the quantity is therefore supplemented by direct synthesis of acid from hydrogen and chlorine, or by manufacturing a further supply of salt cake. As for chlorine, so far from it now being deliberately manufactured as an outlet for surplus hydrochloric acid, it is a matter of some difficulty to dispose of the quantity produced in the electrolytic process for making caustic soda.

Salt cake is used to a certain extent in the glass industry, where it serves as a source of sodium; for the manufacture of sodium sulphide and Glauber's salts (*qq.v.*); and, in far larger quantities, as a raw material for the sulphite process of wood pulp and paper manufacture. It is a matter of some difficulty to dispose of all the salt cake now produced; more especially as it is also obtained as a by-product of the potash industry in Germany, and further occurs naturally in Canada. (A. E. H.)

AMERICAN PRACTICE

In England and to some extent on the continent the Le Blanc soda process was the first large scale chemical development. The desired product was soda ash (sodium carbonate, Na_2CO_3) from which it was natural to proceed to sodium bicarbonate (NaHCO_3) soda crystals ($\text{Na}_2\text{CO}_3 \cdot 10\text{H}_2\text{O}$) and caustic soda (NaOH) and later to sodium silicate. But the raw material for soda ash was sodium sulphide (Na_2S) with sulphur as a by-product. The Na_2S was made from sodium sulphate (Na_2SO_4) and the latter in turn came from the reaction of sulphuric acid on common salt (NaCl) with hydrochloric acid as a by-product. In order to dispose of the large quantities of hydrochloric acid it was necessary to convert much of it into chlorine and bleaching powder. Thus the manufacture of such divergent products as acids, alkalis, sodium salts, chlorine and bleach all developed together in one plant, under one management, as the "alkali industry," and all the sodium compounds handled regardless of their nature became the "alkalis."

America with entirely different chemical history never had such an "alkali industry," and does not apply the term "alkali" to such a group of sodium salts. The products of the English "alkali industry" are manufactured in America by at least four distinct groups of the chemical industry, these four groups having very little in common. First, the acid manufacturer: This industry, established about 1800, is responsible for sulphuric acid, hydrochloric acid, salt cake (sodium sulphate, Na_2SO_4) and Glauber's salt ($\text{Na}_2\text{SO}_4 \cdot 10\text{H}_2\text{O}$). Second, the soda industry: Established about 1870, using the ammonia soda or Solvay process exclusively, and responsible for soda ash, sodium bicarbonate, sodium sesquicarbonate, and the major part of the caustic soda. Third, the electrolytic chlorine industry, established about 1890, and responsible for chlorine, bleach, and the remainder of the caustic soda. Fourth, the specialty manufacturer responsible for sodium silicate and sodium sulphide. As to location, the first group will be near important centres of manufacture where acid consumption is large. When the condition of the market warrants it they will also convert nitre cake (NaHSO_4) a by-product of nitric acid manufactured into salt cake by neutralizing. Otherwise it will be sold for its acid content or as a raw material for making sodium sulphide. The second group will be near large salt beds such as those of Michigan, Ohio, New York, Virginia or Kansas. The third group seeks cheap power or cheap fuel, which attracted several of them to Niagara Falls, New York, and others to West Virginia. It is not uncommon for a consumer of chlorine or chlorine and caustic soda to establish an electrolytic plant essentially to care for his own consumption. In this case cheap fuel and power are not necessarily the controlling factors. A consumer of large quantities of caustic soda alone, on the other hand, would buy soda ash and convert it to caustic soda in his causticizing plant. Much of the caustic soda and the chlorine produced in America is for direct consumption and not for sale. The fourth group of specialty manufacturers may be anywhere.

Soda ash, sodium bicarbonate and trona are also produced from the natural alkaline lake brines of California, Wyoming and Canada, but the production is relatively unimportant as yet and is mainly for local consumption. Natural sodium sulphate production from Arizona, Canada, Nevada and Wyoming may possibly amount to 10% of the total sodium sulphate consumed.

Imports of all the group of sodium salts discussed in this article are negligible, and the only ones exported in any considerable quantity are caustic soda and soda ash.

Approximate production in the United States, 1920 census report: Soda ash 1,500,000 tons of which over 1,000,000 tons were for sale; sodium bicarbonate 190,000 tons, salsoda 83,000 tons, sodium sesquicarbonate 38,000 tons, caustic soda 333,000 tons, sodium silicate 336,000 tons, nitre cake 98,000 tons, salt cake 180,000 tons, Glauber's salts 42,000 tons and sodium sulphide 40,000 tons. (J. E. T.)

For modern ideas regarding alkalinity, *see* HYDROGEN-ION CONCENTRATION; INDICATORS; also ACID.

BIBLIOGRAPHY.—The literature of the ammonia soda process is somewhat scanty; apart from the regular technical periodicals such as the *Journal Soc. Chemical Industry*, *Zeitschr. f. angew. Chemie*, *Zeitschr. f. phys. Chemie*, etc., the following may be consulted: G. Lunge, *The Manufacture of Sulphuric Acid and Alkali*, vols. 2 and 3 (1909-11) (a revised edition of this work by A. C. Cumming is in course of publication). *Thorpe's Dictionary of Applied Chemistry* (revised ed. 1921, et seq.); H. Schreib, *Die Fabrikation der Soda nach dem Ammoniakverfahren* (1905), probably the best treatise on ammonia soda; H. Tedesco, *Studien über den Ammoniak soda Prozess* (1910); H. Molitor, *Die Fabrikation der Soda* (1925); a general treatise on ammonia-soda; J. R. Partington, *The Alkali Industry* (1925), a book suitable, mostly, for the general reader; G. Martin, S. Smith, and F. Milsom, *The Salt and Alkali Industry*, etc. (2nd ed. 1920). Consult also the *Annual Reports on Alkali* (Government publication) and standard treatises on inorganic chemistry.

ALKALIMETRY, the determination of the quantity of free alkali (*q.v.*) in a substance. The chief laboratory method is by volumetric analysis. (*See* ACIDIMETRY and CHEMISTRY: Analytical.)

ALKALINE EARTHS. By the early chemists, the term *earth* was used to denote those non-metallic substances which were insoluble in water and were unaffected by strong heating;

and as some of these substances (e.g. lime) were found to be very similar in properties to those of the alkalis, they were called alkaline earths. The alkaline earths, lime, strontia and baryta, were assumed to be elements until 1807, when Sir H. Davy showed that they were oxides respectively of the metals, calcium, strontium and barium. The metals are never found in the uncombined condition, but occur most often in the form of carbonates and sulphates; they form oxides of the type RO, and peroxides of the type RO₂. The oxides of type RO are soluble in water, with generation of heat (e.g., the slaking of lime); the resulting solution possesses a strongly alkaline reaction, due to the presence of the hydroxide R(OH)₂ which rapidly absorbs carbon dioxide on exposure. These oxides and hydroxides are basic in character and dissolve readily in acids with the formation of the corresponding salts. As the atomic weight of the elements increases, it is found that the solubility of the hydroxides in water increases although that of the sulphates decreases.

The metals calcium, strontium and barium oxidize rapidly on exposure. Their salts usually crystallize well, the chlorides and nitrates dissolve readily in water, whilst the carbonates, phosphates and sulphates are either very sparingly soluble or insoluble in water.

ALKALI SOILS. The term "alkali" is applied to those soils in which soluble salts have accumulated in amounts sufficient to cause injury to plant life. The toxic limit varies with the chemical composition of the soluble salts and also depends upon the variety of crop plants grown in the region. Soils of this character are usually found in regions of low rainfall, their origin being traced to the insufficiency of moisture to wash out and carry away the excess of soluble salts resulting from the weathering of the parent soil material. Under certain conditions the soluble salts accumulate at the surface, while under other conditions the greatest accumulation of soluble salts is found in a soil layer at some distance below the surface and varying with the depth to which the light rainfall of the region penetrates the soil or the depth to the water table. Extensive studies of alkali soils have been made in America, Egypt, Hungary and other countries where arid or semi-arid conditions have resulted in the accumulation in the soil of harmful quantities of soluble salts. The salts that most frequently predominate are the carbonates, chlorides and sulphates of sodium, magnesium and calcium, or a mixture of two or more of these salts, but other forms may be encountered. Under the broad definition of alkali soil the reaction is not necessarily alkaline, but under certain conditions the predominating salt may be neutral, as in the vicinity of Great Salt Lake, Utah, where sodium chloride is present in abundance.

Alkali is commonly designated as white alkali or as black alkali, depending upon the appearance of the incrustations caused by excessive accumulations at the surface of the soil. Usually when large quantities of sodium chloride or sodium sulphate accumulate at the surface their presence is marked by white incrustations, hence the term white alkali. Since sodium carbonate, when present in large quantities attacks the vegetable matter of the soil, causing a dark brown stain, it is frequently called black alkali. This classification is not entirely satisfactory since a much less harmful salt, such as sodium chloride, may likewise impart a dark stain to the soil surface. Since the salts of which the alkali is composed are readily soluble in water, it is evident that, while they will remain inactive in a dry soil, they will dissolve when water is added and will move with the moisture. Farmers living in arid regions are familiar with the fact that parts of their fields heavily encrusted with alkali show no such crusts after heavy rains or after the application of irrigation water. The salts dissolve in the water and move down into the soil but again make their appearance at the surface as the water rises and evaporates leaving the salts behind. Many farmers in a new irrigation district have found to their dismay that after a few years of irrigation practice, alkali has appeared at unexpected places. If sufficient water is added not only to dissolve and start a downward movement of the salts, but also to leach them away into the country drainage, no harmful accumulation will occur. In many irrigated areas the greater part of the alkali accumula-

tions in cultivated fields is the result of seepage, by which the soluble salts are moved from higher to the lower areas where there is a tendency for the drainage water to collect. Such accumulations can be prevented if precautions are taken to provide suitable drainage at the time the irrigation project is undertaken. Extensive studies of methods for the reclamation of alkali soils in different areas have been made and it has been demonstrated that where adequate drainage is provided and irrigation water of good quality is available, reclamation can be accomplished.

ALKALOIDS. For reasons given below, it is not possible to give a precise definition of this term, although to the chemist there is no ambiguity in its use. Man had from very early times drugs, but his knowledge of the alkaloids themselves began little more than a century ago. In 1803 Derosne observed that a syrupy extract of opium (*q.v.*), when diluted with water, deposited crystalline matter, which he separated and purified and so prepared the first alkaloid, probably impure narcotine (*q.v.*). He attempted to improve the yield by adding alkali to the diluted opium syrup and obtained a different substance, which undoubtedly contained the alkaloid morphine (*q.v.*). About the same time Séguin made similar observations and also had morphine in his hands. But the crowning achievement of first isolating a typical alkaloid in a pure state and describing its properties in unmistakable terms was reserved for Sertürner, who in 1816 was able to announce that he had found a new organic, alkaline, salt-forming base, apparently related to ammonia, of which he had prepared a number of salts and whose physiological action he had been able to demonstrate. Meanwhile, in 1810, B. A. Gomes, by treating an alcoholic extract of cinchona bark (*q.v.*) with alkali, obtained a precipitate, which he purified by crystallization from alcohol and called "cinchonino." Houtou-Labillardière observed its basic properties and brought it to the notice of his friends Pelletier and Caventou, who, guided by Sertürner's description of morphine as an "organic alkali," were able to show in 1820 that "cinchonino" was a mixture of two substances, which they named quinine and cinchonine. Between 1817 and 1840 practically all the more important alkaloids were isolated, including emetine, veratrine, strychnine, piperine, caffeine, quinine, berberine, coniine, atropine, codeine, thebaine, (*q.v.*), cinchonine (see CINCHONA), hyoscyamine (see HYOSCYAMINE), curarine, quinidine, aconitine and colchicine.

Definition.—The two points Sertürner stressed in his description of morphine—its basic, salt-forming, ammonia-like character and its physiological action—would be enough upon which to frame a definition of the term alkaloid, were it not for the fact that since then substances such as methylamine and amino-acids (*q.v.*), such as asparagine and betaine, have been found in plants. A growing knowledge of the intimate structure of some typical alkaloids, led at one time to confining the term to naturally-occurring derivatives of pyridine (*q.v.*), which is a structural feature of the majority of known alkaloids; further knowledge, however, made it clear that pyridine formed no part of the structure of some alkaloids and this narrow definition had to be abandoned. With our present knowledge, alkaloids may be defined as relatively complex, basic substances, occurring naturally and exhibiting physiological action. The simple substances already referred to, such as methylamine, asparagine and betaine, together with those formerly known as "animal alkaloids," have been grouped together by Barger as "simple natural bases," though it is difficult to draw the dividing line.

General and Special Interest of Alkaloids.—Everyone is familiar with the physiological action of alkaloids, e.g., quinine is

naturally associated with malaria, morphine (*q.v.*) with the relief of pain, cocaine (*q.v.*) with minor surgical operations and atropine (*q.v.*) with the skilled work of the oculist. The chemist on the other hand looks upon alkaloids as fascinating problems for the exercise of his technique and imagination. He has devoted much attention to devising methods for their detection, isolation and purification; and he has displayed considerable ingenuity in splitting them into recognizable fragments, and so acquiring such a knowledge of their intimate structure as will provide a basis for producing them at will in the laboratory. He has begun to take an interest also in the reason for the occurrence of these things in plants and the methods by which they are produced in nature; and one of his aims is to place the pharmacology (*q.v.*) of alkaloids on a sound chemical basis; so that he may know, for example, the nature of the chemical action which takes place when a neutral salt of cocaine is applied to a nerve-ending and local anaesthesia ensues, and is able to explain the remarkable specific toxicity of quinine and emetine to the protozoa which cause malaria and amoebic dysentery, respectively, in man.

Over 800 alkaloids are known but of these only about 24 are in common use, chiefly in medicine, though some of them find other outlets, *e.g.*, strychnine as a vermin killer, quinine and pilocarpine as cosmetics, while certain of the cinchona alkaloids are used for rendering woollen textiles moth-proof. They are comparatively restricted in their distribution among plants, occurring chiefly in the Rubiaceae, Papaveraceae, Fumariaceae, Solanaceae, Leguminosae and Apocynaceae, and to a less extent in the Rosaceae, Gramineae, Labiatae and Compositae. Where alkaloids do occur they are to be found in all parts of the plants, but especially in the barks and fruit-rinds of perennial species, the leaves and seeds of annual plants and the roots of biennials. They tend to accumulate in those parts of a plant which are thrown off at the end of the growing season, and this is one of the principal arguments for the view that alkaloids are of no use to plants, but are mere waste products of metabolism.

Detection and Preparation of Alkaloids.—The processes by which alkaloids are obtained from plants depend upon the complete extraction of the dry ground material (bark, roots, leaves or seeds) with a suitable solvent, usually alcohol or slightly acidified water. The solvent is then distilled off *in vacuo* and the resulting extract diluted with water, made distinctly acid, if necessary, and left to stand to deposit impurities. It is next made alkaline, preferably with sodium carbonate or ammonia, when the bulk of the alkaloid is usually precipitated and can be filtered off. If the alkaloid is soluble in water, other devices involving the use of immiscible solvents (*i.e.*, liquids which, when shaken with watery fluids, will remove soluble substances therefrom and then form a separate layer) and sometimes special precipitants or absorbents have to be adopted. These processes almost invariably yield a mixture of alkaloids, since the latter rarely occur singly in plants. The separation of these mixtures into their components can generally be achieved (*a*) by treating the mixture of bases with various solvents in turn, and (*b*) by converting the partially separated components into salts by exact neutralization with acids and fractional crystallization of the salts. These processes have to be repeated until there are no longer changes in the physical and chemical properties of the fractions. Each kind of alkaloidal plant requires different treatment and long experience has enabled the processes to be greatly simplified for most of the alkaloids which are produced on a large scale for use in medicine, though on the other hand the standard of purity required in these is constantly rising. The balance between quality and expense of production is settled periodically by the standards set up for medicinal alkaloids and their salts in the various national pharmacopoeias (*q.v.*). The criteria of purity for alkaloids are the same as those for any other organic chemical, *viz.*, determination of physical constants such as melting point, boiling point, optical rotation and the chemical composition as determined by ultimate analysis (*see CHEMISTRY: Analytical*). These, the methods of the research laboratory, are those which the works chemist and the analyst must always have in mind as the ultimate court of appeal in evolving their short routes to control of quality in alkaloids.

The analytical work of the toxicologist in connection with alkaloids is important. The methods by which poisonous alkaloids are extracted from viscera and stomach contents do not differ in principle from those for the extraction of alkaloids from plant material, but in these cases the problem is greatly complicated by the risks of loss by decomposition of the small quantities of alkaloid to be recovered. The usual methods of purification and conversion into identifiable derivatives cannot be applied to these minute quantities; so use has to be made of crystalline form, colour tests which most of the alkaloids give with certain reagents, or in a few cases special pharmacological tests, methods which are perfectly satisfactory in the hands of experts.

Determination of the Intimate Structure of Alkaloids.

—A few of the alkaloids are liquid and volatile and contain only three elements—carbon, hydrogen and nitrogen; but most of them contain oxygen in addition, and are colourless, crystalline solids. Most alkaloids are optically active (*see STEREOCHEMISTRY*) and in a few cases the salts show an optical activity opposite in kind to that of the base. Regarding the alkaloids as extensively substituted ammonias, those containing two atoms of nitrogen should be capable of forming salts containing two molecules of monobasic acids, and this is so with some alkaloids such as quinine, $C_{20}H_{24}O_2N_2$ (*q.v.*), but quite frequently, as in the case of strychnine (*q.v.*), also containing two atoms of nitrogen, the alkaloid combines with only one molecule of a monobasic acid, so that its hydrochloride is represented by the formula $C_{21}H_{22}O_2N_2 \cdot HCl$, and this difference in the basicity of the two nitrogen atoms must be taken into account in assigning constitutional formulae (*see CHEMISTRY: Organic*) to such alkaloids.

In most cases the nitrogen atoms are tertiary, that is, each is united to three different carbon atoms, one of which in such cases is generally in a methyl group, so that the state of such nitrogen atoms can be graphically represented by (*a*).

Such a group is called a methylimino-group, and a method of estimating these in alkaloids has been devised. Sometimes a secondary nitrogen group is present, *e.g.*, ammonia, NH_3 , in which only two of the hydrogen atoms have been replaced by carbon linkages (*b*). The hydrogen of a secondary nitrogen group can in most cases be replaced in an alkaloid by a methyl group, and the secondary nitrogen (*b*) is thereby converted into a methylimino-group (*a*) which can be estimated.

By similar means it is possible to discover how the oxygen atoms in an alkaloid are built into the molecule. Most frequently they are present as hydroxyl ($\cdot OH$) groups or derivatives of such groups, such as methoxy ($\cdot OCH_3$), acetoxy ($\cdot OCOCH_3$) or benzoxy ($\cdot OCO \cdot C_6H_5$). Occasionally a carboxyl group ($\cdot COOH$) is present, either as such or linked up with the nitrogen to form a betaine (*q.v.*) or with its hydrogen atom replaced by methyl forming a methyl ester. There are now well-established methods of ascertaining the presence or absence of all these various types of groups, and after a preliminary investigation of a new alkaloid in this fashion the chemist arrives at a point at which he can write the empirical formula of the alkaloid in some such extended form as (*c*), that is, he has still to ascertain how the alkaloidal nucleus, consisting of x carbon atoms and y hydrogen atoms is built up, and how the groups shown in brackets are built into it. This further information is generally obtained by breaking up the alkaloid chemically into small fragments, examining each of the pieces in the same way as the parent alkaloid was examined, and going on with this process until a recognizable fragment, which may be any one of the thousands of known organic compounds, is found. With that first clue to guide him, and within the limits rigidly prescribed by all he knows as to the composition and reactions of the alkaloid, the chemist can then proceed to visualize a constitutional formula. This breaking-down process is generally accomplished by carefully regulated oxidation of the alkaloid, with such agents as potassium permanganate, chromic acid or

nitric acid, substances which burn off a few carbon atoms at a time leaving products which generally become simpler in character; or a more complicated process called "exhaustive methylation" may be used, in which the nitrogen atom of a carbon-nitrogen ring is loaded with substituents until it breaks from its cyclic carbon attachments leaving fragments either recognizable or convertible into recognizable substances.

The Opium Alkaloids.—Opium (*q.v.*) contains at least 25 alkaloids of which morphine (*q.v.*) is by far the most important, followed by codeine (morphine methyl ether), thebaine, narcotine, papaverine, and protopine (*qq.v.*). Much progress has been made in the determination of the intimate structure of the alkaloids of opium and they can all be regarded in a broad sense as derivatives of isoquinoline. Thus the five minor alkaloids, papaverine, laudanose, codamine, laudanine and laudanidine, form a group of substituted *l*-benzylisoquinolines; narcotine and narceine (*q.v.*) are *l*-meconylisoquinolines, and as the meconyl residue $\cdot\text{CH}\cdot\text{C}_6\text{H}_2(\text{OMe})_2\text{CO}\cdot\text{O}$ itself can be regarded as derived from benzyl, $\text{C}_6\text{H}_5\text{CH}_2$; all seven alkaloids are derivatives of *l*-benzylisoquinoline.

The next group of opium alkaloids, morphine, codeine and thebaine are more condensed and more complex in structure. The simplest member of the group to which they belong is glaucine, found in the yellow-horned poppy, *Glaucium luteum*, but not in the opium poppy. Glaucine has been synthesized from laudanose by a simple reaction, which gives rise to a phenanthrene (*q.v.*) complex by internal condensation within the benzylisoquinoline structure and so this whole group of alkaloids is conveniently spoken of as the phenanthrene group. Synthesis of the simpler members of this group is in progress, but their representatives in opium, the three alkaloids just mentioned, constitute an interesting variation on the typical structure of the phenanthrene group and for them possible formulae—of which those of Pschorr (1905), Knorr and Horlein (1906), and Gulland and Robinson (1923) may be mentioned—are still being discussed.

A third group is represented in opium by two members, protopine and cryptopine. The former is almost the typical alkaloid of the poppy order (Papaveraceae) since it has been found in most species of this order, the alkaloids of which have been systematically examined. This group can be regarded as developed from berberine (*q.v.*), though curiously enough no alkaloids of the berberine type have been found in any member of the poppy order. Their intimate structure has been determined by W. H. Perkin, in whose laboratory both protopine and cryptopine have been synthesized (1926).

ALKANET, a plant, *Alkanna* or *Anchusa tinctoria*, of the family Boraginaceae, also known as orchanet, dyer's bugloss, Spanish bugloss or bugloss of Languedoc, which is grown in the south of France and on the shores of the Levant. Its root yields a fine red colouring matter which has been used to tint tinctures, oils, wines, varnishes, etc.

AL-KASR AL KEBIR: see KASR AL KEBIR.

ALKMAAR, town in the province of North Holland, Holland, 24½ m. by rail north-north-west of Amsterdam, communicating with Haarlem and Amsterdam, and on the North Holland canal. Pop. (1927) 27,304. The name Alkmaar ("all sea") first occurs in the 10th century and recalls the original situation of a fishing village in the midst of marshes and lakes. The first charter was dated 1254; charters (1436 and 1437) of Philip the Good of Burgundy established an oligarchy on grounds of previous mismanagement; much damage was done in wars between Hollanders and Frisians, and the Gelderland and Frisians

captured the town in 1517. In 1573 it successfully sustained a siege by the Spaniards. It acquired an important trade after reclamation of the surrounding swamps from 1685 onwards. In 1799 it gave its name to a convention by which the Russo-British army evacuated Holland. It is a typical North Holland town, with tree-lined canals and brightly coloured 17th century houses. The city walls have been replaced by boulevards and there is a park with a monument commemorating the siege by the Spaniards in 1573. The Groote Kerk (1470–1498) has the tomb of Floris V., count of Holland (d. 1296). In the town hall (1507) are the library and a small museum with two pictures by Caesar van Everdingen, who, with his brother Allart van Everdingen (*q.v.*), was a native of the town. The weigh-house (1582) has a quaint gable and tower. Alkmaar has a flourishing butter and cheese trade, and is a centre of cheese export. It is also a considerable market town. Tramways connect Alkmaar with Egmond and the summer resort of Bergen, sheltered by woods and dunes.

ALLACCI, LEONE (LEO ALLATIUS) (1586–1669), Greek scholar and theologian, and a voluminous writer, was born in the island of Chios. His early years were passed in Calabria and at Rome, where he finally settled as teacher of Greek at the Greek college, at the same time devoting himself to the study of classics and theology. Allacci was sent to superintend the removal to Rome of the 196 cases of mss. from Heidelberg presented by the elector Maximilian of Bavaria to Pope Gregory XV. This collection (*bibliotheca Palatina*) was incorporated with the Vatican library. On the death of Gregory, Allacci became librarian to Cardinal Berberini, and subsequently (1661) librarian of the Vatican, which post he held till his death.

ALLAHABAD, a city of British India, the capital of the United Provinces of Agra and Oudh, giving its name to a district and a division. The city (pop. 157,220 in 1921) is situated at the confluence of the Ganges and the Jumna rivers, 564 m. from Calcutta by rail. Its most conspicuous feature is the fort, at the junction of the rivers. It contains one of Asoka's pillars: also the remains of a splendid palace, erected by the Emperor Akbar, and once a favourite residence of his; also an important arsenal. Outside the fort the places of most historic interest are the tomb and gardens of Khasru, the son of the Emperor Jehangir, and the Jama Masjid or Great Mosque. Allahabad (Illahabad) was the name given to the city when Akbar built the fort. To the Hindus it is still known by its ancient name of Prag or Prayag ("place of sacrifice"), and is a noted resort of Hindu pilgrimage. A bathing festival, known as the Magh-mela, is held at the confluence of the rivers during the Hindu month of Magh. It is attended by as many as 250,000 persons in ordinary years and every twelfth year it becomes the Kumbh-Mela, when as many as a million devotees will crowd to it from all parts of India. Allahabad was taken by the British in 1765 from the wazir of Oudh, restored to him in 1771, and by him finally ceded together with the district to the British in 1801, in commutation of the subsidy which the wazir had agreed to pay for British protection. During the Mutiny of 1857 (see INDIAN MUTINY) Allahabad became the scene of one of the most serious outbreaks and massacres which occurred in the North-Western Provinces. The fort was held by a little garrison of Europeans and loyal Sikhs, until it was relieved by Gen. Neill on June 11 of that year.

The modern buildings of Allahabad include Government House, the High Court, the University, the Mayo memorial and town hall, the Muir central college, the Thornhill and Mayne memorial library and museum, the Naini central jail and the Anglican and Roman Catholic cathedrals. Both rivers are crossed by fine rail-

way bridges; and the place is an important railway centre. The military cantonments contain accommodation for all three arms and are the headquarters of a brigade. At Allahabad is published the *Pioneer*, perhaps the best known English paper in India. It is the home of the parent university of the provinces, from which most of the others have branched off; and it is a centre of numerous educational and missionary institutions.

The district of Allahabad has an area of 2,858 sq.m. In shape it is an irregular oblong, and it is very difficult to define its boundaries, as at one extremity it wanders into Oudh, while on the south the villages of the State of Rewa and those of this district are intermingled. The Jumna and the Ganges enclose within their angle a fertile tract well irrigated with tanks and wells. The East Indian railway and the Grand Trunk road afford the principal means of land communication. In 1921 the population was 1,404,445.

The present division of Allahabad has an area of 10,242 sq.m. The population in 1921 was 4,795,666. It comprises the five districts of Farrukhabad, Etawah, Cawnpore, Fatehpur and Allahabad.

ALLAMANDA, named after J. N. S. Allamand (1713-87), of Leyden, a genus of shrubby, evergreen climbers, belonging to the family Apocynaceae, and a native of tropical America.

ALLAN, DAVID (1744-1796), Scottish historical painter, was born at Alloa. On leaving Foulis's academy of painting at Glasgow (1762) Lord Cathcart and Erskine of Mar furnished him with the means of proceeding to Rome (1764), where he remained for a number of years. Returning from Rome in 1777, he lived for a time in London. In 1780 he removed to Edinburgh, where he was appointed director and master of the Academy of Arts. There he painted and etched in aquatint a variety of works, those by which he is best known—as the "Scotch Wedding," the "Highland Dance," the "Repentance Stool," and his "Illustrations of the Gentle Shepherd"—all being remarkable for their comic humour. Allan died at Edinburgh on Aug. 6, 1796.

ALLAN, SIR HUGH (1810-1882), Canadian financier, was born on Sept. 29, 1810, at Saltcoats, Ayrshire, Scotland. He emigrated to Canada in 1826, and in 1831 entered the employ of the chief shipbuilding and grain-shipping firm of Montreal, of which he became a junior partner in 1835. In 1853 he organized the Allan line of steamships, plying between Montreal, Liverpool and Glasgow; till his death he was closely associated with the commercial growth and prosperity of Canada, and in 1871 was knighted in recognition of his services. In 1872-73 he obtained from the Canadian Government a charter for building the Canadian Pacific railway, but the disclosures made with reference to his contributions to the funds of the Conservative Party led to the Pacific scandal (see CANADA, History), and that company was soon afterwards dissolved. He died in Edinburgh on Dec. 9, 1882.

See J. C. Dent, *Canadian Portrait Gallery* (1881).

ALLAN, SIR WILLIAM (1782-1850), Scottish historical painter, was born in Edinburgh, and studied at the school of design in his native city. Allan spent some years in Russia between 1805 and 1814 and travelled extensively in Southern Russia, bringing back a portfolio of vivid sketches which provided material for much of his later work. In 1814 he returned to Edinburgh and in the two following years exhibited at the Royal Academy "The Circassian Captives" and "Bashkirs conducting Convicts to Siberia." In the next 20 years he established his fame by the illustration of Scottish history in a series of works which included "Archbishop Sharpe on Magus Moor"; "John Knox admonishing Mary Queen of Scots" (1823), engraved by Burnet; "Mary Queen of Scots signing her Abdication" (1824); and "Regent Murray shot by Hamilton of Bothwellhaugh." The last subject procured his election as A.R.A. (1825). In 1834 he visited Spain and Morocco, and in 1841 went again to St. Petersburg, when he undertook, at the request of the tsar, his "Peter the Great teaching his Subjects the Art of Shipbuilding", exhibited in London in 1845, and bought for the Winter Palace of St. Petersburg. Allan received many honours, including that of knighthood in 1842. He died on Feb. 22, 1850.

ALLAN-DESPRÉAUX, LOUISE ROSALIE (1810-1856), French actress, was "discovered" by Talma in Brussels as a child, when she played Joas. She played children's and then *ingénue* parts at the Théâtre Français, and in 1831 began to play at the Gymnase. During her six years at the Gymnase she made a great name. Madame Allan (she married an actor in the Gymnase company) then went to St. Petersburg, and there discovered *Un Caprice* by Alfred de Musset, made a success of it, and on her return to Paris chose it for her reappearance at the Théâtre Français. This was the beginning of Alfred de Musset's success as a dramatist. Madame Allan held her own as an actress even when she appeared by the side of Rachel. She died at the height of her success in 1856.

ALLANTOIN is found in the allantoinic liquid of the cow, and in the urine of sucking calves. It forms glancing prisms of neutral reaction slightly soluble in water. It can be obtained by the oxidation of uric acid by means of lead dioxide, manganese dioxide, ozone or potassium permanganate, and has been synthesized by E. Grimaux by heating one part of glyoxylic acid with two parts of urea (*q.v.*) for ten hours at 100° C. It is the diuride of glyoxylic acid, with the formula

ALLARGANDO (Ital.), a musical term indicating a slackening of the speed and a general increase of weight and breadth in the style of performance.

ALLBUTT, SIR THOMAS CLIFFORD (1836-1925), British physician, was born at Dewsbury, Yorkshire, July 20, 1836. Educated at St. Peter's school, York, and Caius college, Cambridge, he studied medicine at St. George's hospital, London, and afterwards in Paris, subsequently practising in London and Leeds. He carried out much valuable work on the pathology of the nervous system, and made important investigations of tetanus and hydrophobia, devoting, in addition, considerable time to ophthalmoscopy and inventing the short clinical thermometer.

He was consulting physician to many institutions and from 1889 to 1892 was a commissioner in lunacy. In 1892 he became regius professor of physic at Cambridge, in 1907 was created K.C.B. and in 1920 a privy councillor. He died at Cambridge, Feb. 22, 1925.

BIBLIOGRAPHY.—Allbutt's published works include *The Use of the Ophthalmoscope in Diseases* (1871); *On Scrofulous Neck* (1885); *Diseases of the Heart* (Lane Lectures, 1896); *Historical Relations of Medicine and Surgery* (1905); *Greek Medicine in Rome* (Fitzpatrick lectures, 1909-10); *Diseases of the Arteries and Angina Pectoris* (1915); *Science in the School* (1917) and *Notes on the Composition of Scientific Papers* (3rd ed., 1923). He also edited *A System of Medicine* and *A System of Gynaecology* (1896, 1899, 1907).

ALLEGHENY MOUNTAINS or **THE ALLEGHENIES**, a name formerly applied to all the Appalachian mountains (*q.v.*), and now, sometimes, to all that system lying west and south of the Hudson river, being steep and narrow-crested in Pennsylvania (1,500-1,800ft.), in Maryland, Virginia and West Virginia rising to above 4,000ft. and with broader crests. It is also used to include the ridges (the Allegheny ridges) parallel to the Blue ridge; the north-western part of this region is called the Allegheny Front; and is characterized by a bold south-eastward facing escarpment and a gentle north-westward slope. The Allegheny plateau is the north-westernmost division of the Appalachian system; it is an eroded mass of sedimentary rock sloping north-westward to the Lake plains in the region of the Great Lakes and reaching south-west from the Catskill (*q.v.*) region of New York State to the Cumberland plateau region in Tennessee. The Alleghenies, which once formed a barrier to western communication, have long since been crossed by numerous railways and highways which follow the lower elevations or the "water gaps" of the eastward-flowing streams.

ALLEGHENY RIVER, a river of Pennsylvania and New York and the principal tributary of the Ohio river, whose source is the confluence of the Allegheny and the Monongahela at Pittsburgh. The Allegheny rises in the high, hilly plateau region of

Potter County, Pa., at an elevation of about 2,250ft. above sea-level. From its source it flows in a general north-westerly direction about 80m., crossing into New York, to a point 11m. N. of the State line. Here it turns abruptly south-west and continues in this direction for 120m. to the central part of Venango county, Pennsylvania. It then turns to the south-east and again south-west to its confluence with the Monongahela at Pittsburgh. Its total length is about 310m. and its drainage basin 11,400 sq. miles. The topographical character of its drainage basin ranges

PART OF A TOW ON THE ALLEGHENY RIVER OF 9 BARGES OF STEEL PRODUCTS FROM PITTSBURGH AND 2 BARGES OF COAL FOR THE FUEL OF THE STERN-WHEEL STEAMER DURING THE TRIP

from the steep hills and broken country of the eastern slope to the comparatively level marshy western slope. The chief tributaries of the Allegheny are Conewango creek (which flows from the lake region of Chautauqua county, N.Y.), French creek, and Clarion and Kiskiminetas rivers. The Allegheny once served as an important highway for keel-boat navigation and later for transporting the petroleum and coal produced along its banks, but this was only before the beginning of railway competition. The canalized portion of the river, extending from Pittsburgh to Natrona (24m.) and seven feet in depth, has an annual traffic valued at about \$12,000,000.

ALLEGIANCE, the duty which a subject or citizen owes to the State or to the sovereign of the State to which he belongs. It is often used by English legal commentators in a larger sense, divided by them into natural and local, the latter applying to the deference which even a foreigner must pay to the institutions of the country in which he happens to live; but it is in its proper sense, in which it indicates national character and the subjection due to that character, that the word is important. In that sense it represents the feudal *liege homage*, which could be due only to one lord, while simple homage might be due to every lord under whom the subject held land. The English doctrine asserted that allegiance was indelible: *Nemo potest exuere patriam*.

It was said to be a debt and duty to the sovereign co-extensive with the life of the subject. As Blackstone wrote: "It is a principle of universal law that the natural-born subject of one Power cannot by any act of his own (no, not by swearing allegiance to another) put off or discharge his natural allegiance to the former; for this natural allegiance was intrinsic . . . and cannot be diverted without the concurrent act of that Prince to whom it was first due." This doctrine was one of the causes of the war of 1812 with the United States, which had already rejected it. Eventually, after much controversy with Great Britain, Congress in 1868 ordained that "The right of expatriation is a natural and inherent right of all people, indispensable to the enjoyment of the rights of life, liberty and the pursuit of happiness," and one of the "fundamental principles of the Government." In the same year a Royal Commission was set up by the British cabinet to enquire into the subject, resulting in the Naturalization Act 1870, whereby for the first time British subjects, whether natural-born or naturalized, were enabled, apart from an Act of Parliament

or cession of British territory, to renounce their nationality and allegiance. This right of expatriation was substantially re-enacted by the British Nationality and Status of Aliens Act 1914-22. By s. 13 "a British subject, who when in a foreign State and not under any disability, by obtaining a certificate of naturalization or by any other voluntary and formal act becomes naturalized therein, shall thenceforth be deemed to have ceased to be a British subject." And by s. 14 a natural-born British subject who has become a subject of a foreign State may, if of full age and not under disability, make a declaration of alienage. But it was held in *Lynch's Case* (1903), 1 K.B. 444, that a British subject could not become naturalized in an enemy's country during time of war. Taking an oath of allegiance to the enemy State was an act of treason. It would appear, however, from the decision in *Pedlar v. Johnson* (1920), 2 T.R. 450, that a British subject may become naturalized in a neutral State and engage in acts of hostility against his State of origin without sacrificing his rights as a friendly alien. Before a certificate of naturalization can become operative, the applicant must take the following oath of allegiance: "I, A. B., swear by Almighty God that I will be faithful and bear true allegiance to His Majesty, King George the Fifth, His Heirs and Successors, according to law." Emigration to an uncivilized country leaves British nationality unaffected: indeed the right claimed by all States to follow with their authority their subjects so emigrating is one of the usual and recognized means of colonial expansion. (See OATH, NATIONALITY, and NATURALIZATION.)

See Salmond, "Citizenship and Allegiance" in the *Law Quart. Rev.*, vols. 17 and 18; and J. A. Foote, *Private Inter. Law*, 5th ed. (1925). (J. W.; H. H. L. B.)

ALLEGORY, a figurative representation conveying a meaning other than and in addition to the literal. It is generally treated as a figure of rhetoric, but the medium of representation is not necessarily language. An allegory may be addressed to the eye, and is often embodied in painting, sculpture or some form of mimetic art. The etymological meaning of the word is wider than that which it bears in actual use. An allegory is distinguished from a *metaphor* by being longer sustained and more fully carried out in its details, and from an *analogy* by the fact that the one appeals to the imagination and the other to the reason. The fable or parable is a short allegory with one definite moral. The allegory has been a favourite form in the literature of nearly every nation. The Hebrew scriptures present frequent instances of it, one of the most beautiful being the comparison of the history of Israel to the growth of a vine in the 80th psalm. In classical literature one of the best-known allegories is the story of the belly and the members in the speech of Menenius Agrippa (Livy ii. 32, Plutarch's *Life of Coriolanus*, and Shakespeare's play derived therefrom); and several occur in Ovid's *Metamorphoses*. Perhaps the most elaborate and the most successful specimens of allegory are to be found in the works of English authors. Spenser's *Faerie Queene*, Swift's *Tale of a Tub*, Addison's *Vision of Mirza*, and, above all, Bunyan's *Pilgrim's Progress*, are examples which it would be difficult to match in elaboration, beauty and fitness, from the literature of any other nation.

ALLEGRI, GREGORIO (1582-1652), Italian priest and composer, was born at Rome and studied music under G. Maria Nanini, the friend of Palestrina. He was a member of the Sistine chapel choir from 1629 until his death on Feb. 18, 1652. His most famous composition is the *Miserere*, performed once a year in Holy Week at the Sistine chapel, the score of which was jealously guarded for a century. But in 1769 Mozart, then a boy of 13, heard it and wrote it down from memory—a wonderful feat—and Dr. Burney afterwards (1771) obtained a copy and published it. Two volumes of concertos (published 1618-19), and two volumes of motets (published 1620-21) are available, but much of his work remains in manuscript.

ALLEGRO, an Italian word meaning literally "cheerful," which, however, as used in music has come by a natural process to mean a quick or lively rate of speed, coming between *andante* and *presto*. It is also used of a separate piece of music, or of a movement in a sonata, symphony, etc. The diminutive form *allegretto* signifies a speed somewhat less fast.

ALLEINE, JOSEPH (1634–1668), English Nonconformist divine, was born at Devizes, Wiltshire, and educated at Oxford, where he became a fellow and tutor of Corpus Christi. He was curate to George Newton, vicar of St. Mary Magdalene, Taunton, from 1655 to 1662, when both he and his vicar were ejected for nonconformity. He was several times imprisoned for preaching during the remaining six years of his life, which were spent in wandering from one place of temporary safety to another. He died on Nov. 17, 1668. Alleine was one of the best loved of the Puritan preachers, and a considerable scholar. His *Alarm to the Unconverted* (1672) had an enormous circulation.

See *Life*, edited by Baxter; *Joseph Alleine: his Companions and Times*, by Charles Stanford (1861); Wood's *Athenae*, iii. 819.

ALLEINE, RICHARD (1611–1681), English Puritan divine, was born at Ditcheat, Somerset, where his father was rector. He was a younger brother of William Alleine, the saintly vicar of Blandford. Richard was educated at St. Alban's hall, Oxford, and New Inn, and in 1641 became rector of Batcomb (Somerset). He was one of the 2,000 ministers ejected in 1662. The Five Mile Act drove him to Frome Selwood, and in that neighbourhood he preached until his death on Dec. 22, 1681. His most famous work is *Vindiciae Pietatis* (which first appeared in 1660).

See Calamy, *s.v.*; Palmer's *Nonconf. Mem.* iii. 167–168; C. Stanford's *Joseph Alleine; Researches at Batcomb and Frome Selwood*; Wood's *Athenae* (Bliss), iv. 13.

ALLELOMORPH, the name applied to each of a pair of characters in Mendelian inheritance. (See HEREDITY, MENDELISM.)

ALLEMANDE, a name for two kinds of dance, one a German national dance, in 2–4 time, the other somewhat resembling a waltz (from Fr. for German). In music, it signifies a certain kind of movement in a suite, usually following the prelude and preceding the courante (*q.v.*), with which it is contrasted in rhythm; but this has no connection with the dance. The name, however, is also applied to pieces of music based on the dance movement, examples of which are found in Beethoven's German dances for the orchestra. (See DANCE.)

ALLEN, ETHAN (1739–1789), American soldier, was born at Litchfield, Conn., on Jan. 10, 1739. He removed, probably in 1769, to the "New Hampshire grants," where he took up lands, and eventually became a leader of those who refused to recognize the jurisdiction of New York, and contended for the organization of the "grants" into a separate province. About 1771 he was placed at the head of the "Green Mountain boys," an irregular force organized for resistance to the "Yorkers." On May 10, 1775, soon after the outbreak of the Revolutionary War, in command of a force, which he had assisted some members of the Connecticut assembly to raise for the purpose, he captured Ticonderoga from its British garrison, calling upon its commanding officer—according to the unverified account of Allen himself—to surrender "in the name of the great Jehovah and the Continental Congress." Seth Warner being elected colonel of the "Green Mountain boys" in July 1775, Allen, piqued, joined General Philip Schuyler, and later with a small command, but without rank, accompanied General Richard Montgomery's expedition against Canada. On Sept. 25, 1775 near Montreal he was captured by the British, and remained a prisoner until exchanged on May 6, 1778. Upon his release he was brevetted colonel by the Continental Congress. He then, as brigadier general of the militia of Vermont, resumed his opposition to New York, and from 1779 to 1783, acting with his brother, Ira Allen, and several others, carried on negotiations, indirectly, with Governor Frederick Haldimand of Canada, who hoped to win the Vermonters over to the British cause. He seems to have assured Haldimand's agent that "I shall do everything in my power to make this state a British province." In March 1781, he wrote to Congress, with characteristic bluster, "I am as resolutely determined to defend the independence of Vermont as Congress that of the United States, and rather than fail will retire with the hardy Green Mountain boys into the desolate caverns of the mountains and wage war with human nature at large." He removed to Burlington, Vt., in 1787, and died there February 11, 1789. He was, says Tyler, "a blustering frontier hero—an able-

minded ignoramus of rough and ready humour, of boundless self-confidence, and of a shrewdness in thought and action, equal to almost any emergency." Allen wrote a *Narrative of Colonel Ethan Allen's Captivity* (1779), the most celebrated book in the "prison literature" of the American revolution; *A Vindication of the Inhabitants of Vermont to the Government of New York and their Right to form an Independent State* (1779); and *Reason, the Only Oracle of Man* (1784).

Ethan's youngest brother, IRA ALLEN (1751–1814), born on April 21, 1751 at Cornwall, Conn., also removed to the New Hampshire grants, where he became one of the most influential political leaders. In 1775 he took part in the capture of Ticonderoga and the invasion of Canada. He was a member of the convention which met at Winchester, Vt., and in January 1777 declared the independence of the New Hampshire grants; served (1776–1786) as a member of the Vermont council of safety; conducted negotiations, on behalf of Vermont, for a truce with the British and for an exchange of prisoners, in 1781; served for eight terms in the general assembly, and was State treasurer from 1778 to 1786 and surveyor general from 1778 to 1787. In 1789, by a gift of £4,000, he made possible the establishment of the University of Vermont, of which institution, chartered in 1791 and built at Burlington in deference to his wishes, he was thus virtually the founder. In 1795, on behalf of the State, he purchased from the French government arms for the Vermont militia, of which he was then the ranking major general, but he was captured by a British cruiser west of Ireland on his return journey, was charged with attempting to furnish insurrectionary Irish with arms, and after prolonged litigation in the British courts, the case not being finally decided until 1804, returned to Vermont in 1801. During his absence he had been dispossessed of his large holdings of land through the operation of tax laws, and to escape imprisonment for debt, he removed to Philadelphia, where on Jan. 4, 1814 he died. He published a dull and biased, but useful *Natural and Political History of Vermont* (1798), reissued (1870) in vol. i. of the *Collections of the Vermont Historical Society*.

J. B. Wilbur, *Ira Allen, Founder of Vermont* (2 vol., 1928); Henry Hall's *Ethan Allen* (New York, 1892) may be consulted. The best literary estimate may be found in M. C. Tyler's *Literary History of the American Revolution* (1897). See also John Spargo, *Ethan Allen at Ticonderoga* (1926); John Pell, *Ethan Allen* (1929).

ALLEN, FREDERICK MADISON (1879–), American physician, was born in Des Moines, Ia., on March 16, 1879. He graduated at the University of California in 1902, studied medicine for three years in the University of Chicago, and in 1907 graduated in medicine at the University of California. He made researches on diabetes at the Harvard medical school in 1909–12 and at the Rockefeller institute for medical research in 1913–18. In 1920 he was made director of the Physiatriic institute, Morristown, N.J., where he continued investigation and treatment of diabetes and related disorders. In 1922 he became the editor of the *Journal of Metabolic Research*.

His published writings include *Studies Concerning Glycosuria and Diabetes* (1913), *Total Dietary Regulation in the Treatment of Diabetes*, with E. Stillman and R. Fitz (1919), and *Treatment of Kidney Diseases and High Blood Pressure* (1925).

ALLEN, GEORGE (1832–1907), English engraver and publisher, was born at Newark-on-Trent on March 26, 1832, and died at Orpington, Kent, on Sept. 5, 1907. He was apprenticed to a Clerkenwell builder, and became a skilled joiner. He came into contact with Ruskin at Ruskin's drawing class at the Working Men's college, and was closely associated with him as general assistant engraver and publisher for 50 years. He studied mezzotint under Lupton, under J. H. Le Keux, and produced the plates for Ruskin's later books. In 1862 Allen went to Mornex, Savoy, where Ruskin then thought of settling, and there he made a considerable collection of minerals. He began his publishing business in 1871, in his cottage at Keston, and afterwards in the garden of his house at Orpington, as the publisher of Ruskin's works. Twenty years later he removed to London, and began business as general publisher. He was engaged on the library edition of Ruskin's works (1903–11) at the time of his death.

ALLEN, GLOVER MERRILL (1879–), American naturalist, was born in Walpole, N.H., on Feb. 8, 1879. He was educated at Harvard university at which he graduated in 1901, received the degree of Ph.D. in 1904 and continued further study in 1906–07. In 1901 he was appointed librarian of the Boston Society of Natural History. In 1907 he began the critical study of mammals in the Museum of Comparative Zoology, Harvard university, and in 1924 was made lecturer in zoology. As naturalist he was a member of several scientific expeditions, notably to the Bahama islands in 1904, to British East Africa in 1909, to Grenada, British West Indies, in 1910, and to the Sudan in 1912. He published, with R. H. Howe Jr., *The Birds of Massachusetts* (1925) and *Birds and Their Attitudes* (1925). His writings include also numerous scientific papers, mainly on birds and mammals.

ALLEN, GRANT (CHARLES GRANT BLAIRFINDIE) (1848–1899), English author, son of a clergyman of Irish descent, was born at Kingston (Ont.), Canada, on Feb. 24, 1848. He was educated partly in America and France, and in England at King Edward's school, Birmingham, and afterwards at Merton college, Oxford. He was for a few years a schoolmaster in Jamaica, but then made his home in England. He died in his house at Hindhead, Surrey, on Oct. 24, 1899. Grant Allen was a voluminous author. His scientific books (such as *Physiological Aesthetics*, 1877; *The Evolutionist at Large*, 1881; *The Evolution of the Idea of God*, 1897) contain much original matter, popularly expressed. He first attracted attention as a novelist with a sensational story, *The Devil's Die* (1888), though this was by no means his first attempt at fiction; and *The Woman who Did* (1895), which had a temporary *succès de scandale* on account of its treatment of the sex problem, inspired many imitations.

ALLEN, SIR HUGH PERCY (1869–), director of the Royal College of Music and professor of music at Oxford university, was born at Reading, Dec. 23, 1869, and received his first appointment as organist of St. Saviour's, Reading, at the age of 11. After holding many similar appointments he became closely associated with the music of both Cambridge and Oxford, in the one case as organ scholar of Christ's College and in the other as organist of New College. In the latter capacity he displayed characteristic energy and enthusiasm in developing the musical life of the university. Concurrently he became known to the London musical public as conductor of the Bach choir, and when on the death of Sir Hubert Parry (q.v.) in 1918 he was chosen to succeed him at the Royal College of Music the wisdom of the appointment (subsequently abundantly justified) was generally recognized. He succeeded Sir Walter Parratt as professor of music at Oxford in the same year and was knighted in 1920.

ALLEN, SIR JAMES (1855–), New Zealand statesman, was born in South Australia on Feb. 10, 1855, his parents settling in New Zealand a year later. He was educated in England at Clifton and St. John's College, Cambridge, and afterwards studied at the Royal School of Mines, in London. Returning to New Zealand, he was, in 1887, elected a member of the house of representatives. He was minister of finance, defence and education from 1912–15, and, in 1915, when a separate ministry of defence was formed, he took charge of it, retaining the post until 1920. It was largely due to his efforts that, in 1914, the New Zealand force was one of the most effective of the British Dominion armies. In the absence of Mr. Massey in England during and after the World War, he acted as prime minister for two years. He was made a K.C.B. in 1917 and was high commissioner for New Zealand in London from 1920 to 1926. His long, practical experience as a Dominion administrator and his sympathetic understanding of the needs of the empire rendered his presence in London especially valuable both to the Dominion and the empire. He is the author of *New Zealand and Federation: The Financial Aspect* (1890), a pamphlet issued by *The Press*, Christchurch, and *New Zealand's Possessions in the South Seas* (1903).

ALLEN, JAMES LANE (1840–1925), American author, was born Dec. 21, 1849, on a small plantation near Lexington, Ky., where he passed most of his early life. He acquired a scholarly

background for his creative work through his study at Transylvania university (then called Kentucky university), his professorship of Latin and English at Bethany college, West Virginia, his teaching of languages in preparatory schools and his own wide reading and early essays in criticism. The landscape and gentle breeding of Kentucky inspired his first ripe and polished series of tales, *Flute and Violin* (1891). These are the dominant notes also in his sketches, *The Blue-Grass Region of Kentucky* (1892), and his early novels, *A Kentucky Cardinal* (1894) and its sequel, *Aftermath* (1895), and *The Choir Invisible* (1897). *A Summer in Arcady* (1896) marks a transition to a second phase in which he is preoccupied with problems, largely of sex, as in *The Mettle of the Pasture* (1903), *The Bride of the Mistletoe* (1909) and *The Doctor's Christmas Eve* (1910), although *The Reign of Law* (1900) concerned itself with a youth whose old-fashioned faith was shattered by his new-found science. His latest novels are more varied. His early poems, beautiful and serious as they were, have never been published in book form. He died in New York, Feb. 18, 1925.

ALLEN, JOEL ASAPH (1838–1921), American zoologist, was born in Springfield, Mass., on July 10, 1838. He attended Wilbraham academy and then studied zoology under Louis Agassiz in the Lawrence scientific school, Harvard university. From 1865 to 1869 and again in 1873 he was a member of scientific expeditions to Florida, the Rocky mountains and Brazil. In connection with these expeditions he collected much zoological material on which he made extensive investigations, the results of which were published chiefly in the *Proceedings of the Boston Society of Natural History*. His *Mammals and Winter Birds of Eastern Florida* (1871) won for him the Humboldt scholarship of the Lawrence scientific school, and placed him in the front rank of American naturalists. In 1871–73 he was lecturer and in 1873–85 assistant in ornithology in the Museum of Comparative Zoology, Harvard. From 1885 until his death he was curator of mammalogy and ornithology in the American Museum of Natural History, New York city. During this period he published a large number of papers on birds and mammals and for more than 30 years gave editorial supervision to all the zoological publications of the museum, about 60 volumes. He took a leading part in organizing the American Ornithologists' Union, edited three issues of its *Check List of North American Birds*, and from 1884 to 1912 edited its official journal *The Auk*, to which he contributed more than 600 papers. His *Autobiographical Notes* (1916) contains a bibliography of his scientific writings, including some 1,400 titles. He died at Cornwall-on-Hudson, Aug. 29, 1921.

Among his more important works, other than those before mentioned, are *The American Bisons Living and Extinct* (1876); with Eliott Coues, *Monographs on North American Rodentia* (1877); *History of North American Pinnipeds* (1880); *Mammals of Patagonia* (1905); *The Influence of Physical Conditions on the Genesis of Species* (1905); and *Ontogenic and Other Variations in Musk-Oxen* (1913).

Chapman, "In Memoriam: Joel Asaph Allen," *The Auk*, new ser. vol. xxxix, pp. 1–14 (1922); and F. M. Chapman, "Joel Asaph Allen," *Nat. Acad. of Sciences, Memoirs*, vol. xxi, (1926).

ALLEN, JOHN (1476–1534), English divine, after studying at both Oxford and Cambridge, was sent by Archbishop Warham on an ecclesiastical mission to Rome. He was one of Wolsey's agents in the suppression of the minor monasteries in 1524–25, and in 1528 became archbishop of Dublin. For four years he was chancellor of Ireland. In 1531 he was fined under the statutes of provisors and praemunire, and in 1534 was murdered by Lord Thomas Fitzgerald's followers.

ALLEN, RICHARD (1760–1831), American negro clergyman, was born of slave parents in Philadelphia, Pa., in 1760. Soon after his birth his parents were sold into slavery in Delaware. At 17 years of age he joined the Methodist Episcopal Church and when 22 years old was licensed to preach. Four years later (1786) he purchased his freedom for \$2,000, Continental money, and returned to Philadelphia. Here he joined St. George's M.E.

Church in which he was permitted to preach to coloured people at 5 o'clock meetings. Dissatisfied with the restrictions placed upon those who attended these meetings, he decided to withdraw. He personally purchased a lot at the corner of 6th and Lombard streets, and moved upon it an old blacksmith shop which he refurbished as a house of worship. Here he organized in 1787 the first church for coloured people in the United States. His followers who congregated here were called Allenites. Despite opposition and a series of obstructive lawsuits, a charter was secured from the General Assembly of Pennsylvania. A new church building was erected and opened in 1794. It was dedicated by Bishop Francis Asbury (*q.v.*) and called Bethel. In 1799 Allen was regularly ordained in the ministry of the Methodist Episcopal Church, the first coloured minister so ordained. In 1816, upon the organization of the African Methodist Episcopal Church, Allen was elected bishop. He died in Philadelphia on March 26, 1831.

See *Centennial Encyclopaedia of the African Methodist Church* (Philadelphia, 1916).

ALLEN or **ALLEYN, THOMAS** (1542–1632), English mathematician, was born at Uttoxeter, Staffordshire, Dec. 21, 1542, and died Sept. 30, 1632. He was educated at Oxford, and found patrons in Henry Percy, 8th earl of Northumberland and Robert Dudley, earl of Leicester. He was on intimate terms with Sir Robert Cotton, William Camden, and their antiquarian associates. His great skill in mathematics and astrology earned him the credit of being a magician; and the author of *Leicester's Commonwealth* accused him of employing the art of "figuring" to further the earl of Leicester's unlawful designs, and of endeavouring by the black art to bring about a match between his patron and Queen Elizabeth. Much of Allen's collection of old manuscripts was presented to the Bodleian library by Sir Kenelm Digby.

ALLEN, VIOLA (1869–), American actress, was born in Huntsville, Ala., on Oct. 27, 1869. She was a daughter of C. Leslie Allen, an actor of ability, and was educated in Boston, Toronto, and New York city. At the age of 13 she made her début in the title-rôle of *Esmeralda* at Madison Square theatre, New York. Later she appeared in leading classical, Shakespearian and comedy rôles with Lawrence Barrett, Tommaso Salvini, Joseph Jefferson, and other noted actors. She created and played leading parts in *Sowing the Wind*, *The Masqueraders*, and *Under the Red Robe*. In 1898 she appeared with marked success as Gloria Quayle in *The Christian*, by Hall Caine, and in 1902 as Roma in Hall Caine's *The Eternal City*. Beginning in 1903 in a series of Shakespearian productions, she played Viola in *Twelfth Night*, in 1904–05 she appeared as Hermione and Perdita in *A Winter's Tale*, and in 1906–07 she played in a repertoire which included, besides the foregoing, *Cymbeline* and *As You Like It*. During the ensuing ten years she was seen mainly in modern comedy parts, but in 1915 she returned to Shakespearian drama, playing Lady Macbeth in company with J. K. Hackett, and in 1916 she appeared as Mistress Ford in *The Merry Wives of Windsor*. In 1906 she was married to Peter Duryea.

ALLEN, WILLIAM (1532–94), English cardinal, was born at Rossall, Lancs, and died in Rome Oct. 16, 1594. He was educated at Oriel College, Oxford, and became principal of St. Mary Hall. Although he was deprived for refusing the oath of supremacy at Elizabeth's accession, he remained in the University until 1561. He then went to Louvain, but soon returned to England and lived in hiding until 1565. After two years spent in lecturing at the Benedictine college in Malines, he went to Rome and began working on his scheme for the establishment of a Catholic college where English students could be trained in theology. With the help of friends, notably of the Benedictines of neighbouring monasteries, he founded (Sept. 29, 1568), with papal approval and under the patronage of the king of Spain, the English seminary at Douai. He himself became regius professor there. The seminary at Rome, established in the old English hospice there, was also founded by his advice. In 1578 the Flemish insurgents against Spanish rule expelled the English students from Douai, and Allen moved his seminary to Reims, where the translation of the Bible known as the Douai version was begun under his direction.

In 1577 he began to correspond with Robert Parsons, the Jesuit, one of the directors of the many plots against Elizabeth. Under the advice of Parsons the seminary at Rome was handed over to the Society of Jesus to train men for the Jesuit mission to England. Allen left Reims in 1585 for Rome, where he spent the rest of his life. Although he was in reality only the leader of a group of émigrés, Allen was regarded on the Continent, quite wrongly, as the authorized representative of the English Catholics. In this assumed capacity he wrote to Philip II. of Spain after the execution of Mary, Queen of Scots, urging him to invade England and to punish Elizabeth, "that woman hated by God and man."

After much negotiation, he was made cardinal by Sixtus V. Aug. 7, 1587. One of his first acts was to issue, under his own name, two violent works for the purpose of inciting the Catholics of England to rise against Elizabeth: "The Declaration of the Sentence of Sixtus V." a broadside, and a book, *An Admonition to the nobility and people of England* (Antwerp 1588). On the failure of the Armada, Philip nominated him to the archbishopric of Malines, but the canonical appointment was never made. Gregory XIV. made him librarian at the Vatican; and he served on the commission for the revision of the Vulgate. He took part in four conclaves, but never had any real influence after the failure of the Armada. Before his death he found reasons to change his mind concerning the wisdom of the Jesuit politics in Rome and England.

Bellesheim, *Wilhelm Cardinal Allen und die englischen Seminare auf dem Festlande* (Mainz, 1885); *First and Second Diaries of the English College, Douai* (London, 1878); Nicholas Fitzherbert, *De Antiquitate et continuatione religionis in Anglia et de Alani Cardinalis vita libellus* (Rome, 1608); E. Taunton, *History of the Jesuits in England* (London 1901); Teulet, vol. v.; the *Spanish State Papers* (Simancas), vol. iii. and iv. A list of Allen's works is given in J. Gillow, *Biographical Dictionary of English Catholics* vol. i. under his name.

ALLEN, WILLIAM (1803–1879), American lawyer and politician, was born in Edenton, N.C., in 1803. When 16 years old he removed to Chillicothe, O., attended the Chillicothe academy, studied law, and at the age of 21 was admitted to the bar. He rapidly attained prominence as a lawyer and in 1833 was elected to Congress as a Democrat, the youngest member, when seated, of the national House. In 1836, following his energetic support of Van Buren's presidential campaign, he was elected to the U.S. Senate, in which he served two terms, 1837–49. In the Senate, in which he was a forceful figure, he received the nicknames "Earthquake Allen," "Petticoat Allen" and the "Ohio Gong," and is said to have originated the famous slogan used so effectively in the presidential campaign of 1844, "Fifty-four forty, or fight!" Following the defeat in 1848 of Lewis Cass, the Democratic candidate for president, whom he most ardently supported, and the expiration soon after of his own term in the Senate, Allen withdrew from active participation in politics until 1873, when he was elected governor of Ohio. While governor, he became a prominent advocate of an irredeemable currency, and in 1875, on the Greenback issue, he was defeated for re-election by Rutherford B. Hayes (*q.v.*). Allen died in Chillicothe, O., on June 11, 1879.

See Reginald Charles McGrane, *William Allen* (Columbus, O., 1925).

ALLEN, ZACHARIAH (1795–1882), American scientist, inventor and manufacturer, was born in Providence, R.I., on Sept. 15, 1795, the son of a wealthy merchant. He graduated at Brown university in 1813, was admitted to the bar in 1815, and in 1822 became engaged in manufacturing enterprises. By the use of his wealth and through his inventions he substantially aided the development of various industries in Rhode Island. In 1821 he constructed the first hot-air furnace for the heating of dwellings. For the purpose of studying advanced mechanical methods he visited in 1825 England, France and the Netherlands. In 1833 he secured the patent for the automatic cut-off valve for steam-engines, his most widely known invention. He made an improved fire-engine, devised a storage reservoir for water-power and was the first to make a calculation of the motive power of Niagara Falls, which he published in *Silliman's Journal* in 1844. Among his published writings are: *The Science of Mechanics* (1829);

Philosophy of the Mechanics of Nature (1852); *The Rhode Island System of Treatment of the Indians, and of Establishing Civil and Religious Liberty* (1876); and *Solar Light and Heat, the Source and Supply* (1879). He died in his native city on March 17, 1882.

See Amos Perry, *Memorial of Zachariah Allen, 1795-1882* (Cambridge, Mass., 1883).

ALLEN, BOG OF, a group of morasses in Kildare, King's County, Queen's County, and Westmeath, Ireland. Clane bog, the eastern extremity, is within 17m. of Dublin, and the morasses extend westward almost to the Shannon. Their total area is about 238,500 acres. The tract of country to which the name is given is intersected by strips of dry cultivated land. The rivers Brosna, Barrow, and Boyne rise in the morasses, and the Grand and Royal canals cross them. The bog has a general elevation of 250ft. above sea level, and the average thickness of the peat beds is 25ft. It rests on clay and marl.

ALLENBY, EDMUND HENRY HYNMAN, 1st Viscount (1861-), British field-marshal, was born April 23, 1861, and joined the Inniskilling Dragoons in 1882. He saw active service early in the Bechuanaland expedition of 1884-85 and in Zululand 1888, and later passed through the Staff College. During the South African war (1899-1902) he took part in the cavalry operations leading to the relief of Kimberley, in the battle of Paardeberg, and in the advance to Pretoria. His command of the 5th Lancers from 1902-05 spread his reputation throughout the Army. After commanding a cavalry brigade, he became inspector of cavalry in 1910 and in 1914 went out to France in command of the cavalry division.

The work of his troops, mounted, during the retreat from Mons and advance to the Aisne, and, dismounted, in holding the line south of Ypres during the critical weeks of October, won high praise in Sir John French's despatches. When a second cavalry division arrived, Allenby was given command of the Cavalry Corps then formed, and in Oct. 1915 he succeeded Sir Charles Monro as commander of the III. Army. Throughout 1916 his Army front was relatively quiet, but in the spring of 1917 it played a foremost rôle in the battle of Arras.

In June Allenby left France to succeed Sir Archibald Murray in charge of the forces in Egypt and Palestine. His first three months on the borders of Palestine, the season being still unsuit-

GENERAL ALLENBY, COMMANDER OF THE BRITISH FORCES IN PALESTINE, WITH HIS STAFF AND ACCOMPANIED BY ITALIAN AND FRENCH OFFICERS, RECEIVED BY THE INHABITANTS IMMEDIATELY AFTER THE FALL OF JERUSALEM

able for operations, were devoted to intensive preparations for an autumn offensive, reorganizing the command, greatly developing the communications, and moving his own General Headquarters from Cairo to the front at Rafa. Complete secrecy and many ruses misled the Turks as to the main point of attack. The strong defences of Gaza were bombarded from Oct. 26 onwards, and serious attacks followed on Nov. 1 to fix the enemy's attention and compel him to draw in his reserves.

Meanwhile, as a necessary preliminary to the real blow, the

outlying bastion of Beersheba, 35 m. E. of Gaza, was gained by a convergent manoeuvre on Oct. 31, a prelude to the decisive attack on Nov. 6 which broke through the enemy's weakened centre and into the plain of Philistia. This compelled a general retreat of the Turks, and the pursuit was pressed so relentlessly that by Nov. 14 the port of Jaffa had been seized, the Turkish armies driven apart in two divergent masses, and Allenby was able to wheel his forces to the right for an advance inland on Jerusalem. The British troops kept too closely on the heels of the Turks for the latter to block the narrow mountain passes, and, despite a stout Turkish resistance almost at the gates of Jerusalem the objective was gained with the surrender of the city on Dec. 9. By the time the winter rains set in the position of the British had been improved and their hold on Jaffa and Jerusalem had been made thoroughly secure.

The further advance initiated in the spring was interrupted by the crisis on the western front, which forced the dispatch to France of most of Allenby's British troops. The depletion was made up by reinforcements from India and Mesopotamia, and the summer of 1918 was devoted to reorganization and the training of these new units. Finally, in mid-September, the carefully planned and prepared offensive was launched. Feinting towards the east bank of the Jordan, to distract the enemy's attention, Allenby secretly concentrated, on the Mediterranean flank, the mass of the infantry and behind them the cavalry. In this way he changed a two-to-one superiority on the general front into a four-to-one superiority at the decisive point of attack. On the night Sept. 18-19 the forces in the hilly centre had attacked to fix the enemy's attention, and at dawn on the 19th the western mass struck; the result was to roll the Turks back north-east, like a door on its hinges.

Through the open doorway the cavalry passed, riding straight up the coastal corridor for 30 m. before swinging east to cut the Turkish communications and close all exits of retreat. Completely trapped, the main Turkish armies were rounded up, while the British cavalry exploited the victory of Megiddo by a swift and sustained pursuit which gained first Damascus and finally Aleppo. The capitulation of Turkey rang down the curtain on this brief and dazzling campaign. Making all allowances for the British superiority in strength, it must rank as one of the masterpieces of military history, as perfect in execution as in design. For his services the victor was promoted field-marshal and raised to the peerage as Viscount Allenby of Megiddo and Felixstowe, receiving also a grant of £50,000.

Though his campaign had been waged beyond the borders of Egypt, Allenby had been throughout responsible for the protection and internal order of the Nile delta, where the military situation and the changed status of Egypt had led to considerable unrest. In 1919 he was appointed British High Commissioner in Egypt, and held the post until 1925, through the long sequence of political trouble and disturbances arising out of the agitation for independence. In such conditions criticism of the administration was inevitable, but it is a testimony to Allenby's impartiality and sympathy that it was rather of the velvet glove than of the iron hand. If the ultimate verdict rests with history, it can at least be recognized now that the prestige of his name was a unique asset, and indeed made him the only possible choice for the post at such a critical period. See PALESTINE, OPERATIONS IN.

(B. H. L. H.)

ALLENSTEIN, a town in East Prussia, Germany, on the river Alle, 100m. N.E. of Thorn by rail. Pop. (1925) 38,065. The town possesses a mediaeval castle, and has courts, with superior courts at Königsberg. The town makes machines, cement, furniture, gloves and umbrellas. It trades in grain, leather and cattle.

ALLENSTEIN-MARIENWERDER, a region composed of districts of the former Prussian provinces of East and West Prussia.

Articles 94-98 of the Treaty of Versailles (*q.v.*) provided that the East Prussian Circles (Kreise) of Allenstein, Ortelburg, Osterode, Sensburg, Johannisburg, Lotzen, Lyck and Neidenburg, in so far as they had not already been ceded to Poland, and further the West Prussian Circles of Marienwerder (east of the

Vistula), Stuhm, Rosenberg and the section of the Circle Marienburg situated east of the Nogat, should declare by a plebiscite whether they desired to belong to Germany or Poland. Until the plebiscite should take place the administration of these Circles was taken over by inter-Allied commissions for East and West Prussia respectively, supported by Allied garrisons.

The plebiscite held on July 11, 1920, was preceded by much agitation and band warfare. In the East Prussian region 98% of the population voted for Germany, in the West Prussian 92%. Both districts were assigned to Germany on the basis of the vote; but, in accordance with the terms of the Treaty of Versailles, a zone 50m. broad and some 30m. long on the east bank of the Vistula near Marienwerder and four villages with the harbour of Kurzebrack on the same river were assigned to Poland in order to secure for the Polish state, at this point, the sovereignty over the course of the Vistula accorded to it by the treaty. The inhabitants of the adjacent East Prussian territory are at all times to have access for themselves and their boats to the Vistula. Three frontier communes in the south-west of East Prussia were also assigned to Poland. On Aug. 16 both the inter-Allied commissions left the plebiscitary areas.

ALLENTIACAN, a small independent linguistic stock of South American Indians, so called from the Allentiacs or Huarpes (Guarpes) who were its most important tribe. The Allentiacs lived in western Argentina, in the vicinity of the lagoon of Huana-cacha on the borders of the provinces of San Luis and Mendoza. They were a fierce tribe of low culture, and have, with most of their neighbours, been extinct since the latter part of the 18th century.

See D. S. Aguiar, *Los Huarpes* (B. Aires, 1900-04); E. Boman, *Antiquités de la Région Andine de la République Argentine*, etc. (Paris, 1908).

ALLENTOWN, a city of Pennsylvania, U.S.A., on the Lehigh river, 56 m. N.N.W. of Philadelphia; the county seat of Lehigh county. It is on the William Penn highway, and is served by the Reading system, the Central Railroad of New Jersey and the Lehigh Valley Railroad, and the Lehigh and New England (for freight only). The area of the city is 9.75 sq. miles. Its population increased from 35,416 in 1900 to 73,502 in 1920, of whom 8,612 were foreign-born (4,219 Slavs); and was 92,563 by the census of 1930.

The city is situated on high ground sloping gently towards the river and commanding diversified views of the surrounding country. Its main streets are crowded with traffic. There were 257 factories in 1927, and the aggregate value of their output was \$98,047,989, which was over five times as much as the value of the manufactured products in 1905. The silk industry, introduced in 1881, developed into the dominating interest, until in 1905 Allentown ranked sixth in the manufacture of silk and silk goods in the U.S.A. Silk is still its leading industry, but there are also extensive iron furnaces, rolling mills, forges and foundries; planing mills and furniture factories; and factories making shoes, cigars, linen thread, barbed wire, cement, firebrick, auto-trucks and mining machinery.

Allentown is the seat of Muhlenberg college for men and Cedar Crest college for women. The former in 1926-27 had an enrolment of 455 in the college; 362 in the summer school, to which women are admitted; 869 in the extension schools, also co-educational; and 200 in the preparatory school affiliated with it.

Allentown was settled in 1751. In 1762 it was laid out as a town by James Allen, the son of a chief justice of the province, after whose family the city is named. In 1811 it was incorporated as a borough, and the name was changed to Northampton; in 1812 it was made the county seat; in 1838 the original name was resumed; and in 1867 it was incorporated as a city. The Lehigh county Historical Society occupies Trout Hall, a home built by William Allen, who settled here in 1702. During the Revolution the Liberty Bell was brought to Allentown from Philadelphia for safe-keeping and for a time was placed in the basement of one of the churches.

Trexler Park, 10 m. N. of the city, is a game preserve containing large herds of buffalo, elk and deer.

ALLEPPEY, a seaport of south India, in the State of Travancore, 33m. south of Cochin, on a strip of coast between the sea and one of those backwaters that here form the chief means of inland communication. Pop. (1921) 32,074. There is a lighthouse 85ft. high. Though the third town in the State in point of population, Alleppey is the first in commercial and industrial importance. It commands a fine harbour, affording safe anchorage for the greater part of the year. It was opened to foreign trade towards the latter end of the 18th century. The exports include pepper, cardamoms, copra, coir, ginger and coco-nuts. There are several oil-mills.

ALLERGY, a hypersensitivity which causes various diseases such as serum sickness, asthma, hay fever and hives. When a foreign protein, say horse serum, is injected into a laboratory animal of another species, it is harmless. But it renders the animal hypersensitive to further injections of the same serum after a period of incubation. When the second injection is given the animal will have a severe reaction which may result in its death. This sensitivity is remarkably specific, and the animal will react only to the type of foreign protein originally given. One hypothesis is that the tissues form antibodies to counteract the original foreign protein and when the second injection is made the antibodies and foreign protein react so violently that destruction of tissue takes place. This has never been experimentally proved.

ALLERTON, ISAAC (1583?-1659), one of the American Pilgrims, was born probably in England about 1583. The first record concerning him is as a merchant in Leyden, Holland. He was a member of the English Separatist Church there and was made a freeman of the city in 1614. On the first voyage of the "Mayflower" in 1620 he came to Plymouth, Mass., and was the fifth to sign the historic "Mayflower Compact" (see MAYFLOWER). One of the most enterprising members of the colony, he took a prominent part in the conduct of its early affairs. As the colony's first assistant or agent he made several voyages to England and also carried on negotiations with the Indian chief Massasoit. A disagreement in 1631 led to his separation from the colony. He went first to Marblehead, Mass., and later, about 1635, to New Amsterdam, now New York, where in 1643 he was made a member of the council. His latter years were spent at New Haven, Conn., where he died in 1659. His daughter Mary, whose death occurred in 1699, was the last survivor of the original "Mayflower" company.

See William Bradford, *History of the Plymouth Plantation* (Boston, 1856, 1898); Annie A. Haxton, *Signers of the "Mayflower Compact"* (1896-99); Edward Beaman Patten, *Isaac Allerton, First Assistant of Plymouth Colony* (1908), and George E. Bowman, *The "Mayflower Compact" and Its Signers* (Boston, 1920).

ALLESTREE or **ALLESTRY, RICHARD** (1619-1681), royalist divine and provost of Eton College, son of Robert Allestree, and a descendant of an ancient Derbyshire family, was born at Uppington in Shropshire. He took an active part in the Civil War, and during the Commonwealth frequently carried despatches between Prince Charles and the English royalists. He was imprisoned for a brief period after one of these missions. At the Restoration he became canon of Christ Church, D.D. and city lecturer at Oxford, in 1663 chaplain to the king and regius professor of divinity, and in 1665 provost of Eton College. He introduced order into the disorganized finances of the college and procured the confirmation of Laud's decree, which reserved five of the Eton fellowships for members of King's College. His additions to the college buildings were less successful; for the "Upper School," constructed by him at his own expense, was falling into ruin almost in his lifetime, and was replaced by the present structure in 1689. Allestree died Jan. 28, 1681, and was buried in the chapel at Eton College, where there is a Latin inscription to his memory.

His writings include many controversial tracts. A share in the composition, if not the sole authorship, of the books published under the name of the author of the *Whole Duty of Man*, has been attributed to Allestree (Nichols's *Anecdotes*, ii. 603), and the tendency of modern criticism is to regard him as the author. His lectures, with which he was dissatisfied, were not published. Alles-

tree was a man of extensive learning, of moderate views and a fine preacher. He was generous and charitable, of "a solid and masculine kindness," and of a temper hot, but completely under control.

ALLEYN, EDWARD (1566–1626), English actor and founder of Dulwich college, was born in London Sept. 1, 1566, the son of an innkeeper. In 1586 his name was on the list of the earl of Worcester's players, and he was eventually rated by common consent as the foremost actor of his time. Ben Jonson bestowed unstinted praise on Alleyn's acting (*Epigrams*, No. 89). Nash expresses in prose, in *Pierce Penniless*, his admiration of him, while Heywood calls him "inimitable," "the best of actors," "Proteus for shapes and Roscius for a tongue." Alleyn inherited house property in Bishopsgate from his father. His marriage, on Oct. 22, 1592, with Joan Woodward, stepdaughter of Philip Henslowe, brought him eventually more wealth. He became part owner in Henslowe's ventures and, in the end, sole proprietor of several play-houses and other profitable pleasure resorts. Among these were the Rose theatre at Bankside, the Paris garden and the Fortune theatre in St. Luke's—the latter occupied by the earl of Nottingham's company, of which Alleyn was the head. He filled, too, in conjunction with Henslowe, the post of "master of the king's games of bears, bulls, and dogs." On some occasions he directed the sport in person, and Stow, in his *Chronicles*, gives an account of how Alleyn baited a lion before James I. at the Tower.

Alleyn's connection with Dulwich began in 1605, when he bought the manor of Dulwich from Sir Francis Calton. The landed property, of which the entire estate had not passed into Alleyn's hands earlier than 1614, stretched from the crest of that range of Surrey hills on whose summit now stands the Crystal Palace, to the crest of the parallel ridge, three miles nearer London, known in its several portions as Herne hill, Denmark hill and Champion hill. He began the task of building and endowing in his own lifetime the College of God's Gift at Dulwich. All was completed in 1617 except the charter or deed of incorporation for setting his lands in mortmain. Tedious delays occurred in the Star Chamber, but the College of God's Gift at Dulwich was founded and endowed under letters patent of James I. dated June 21, 1619. The building had been already begun in 1613 (see DULWICH). Alleyn was never a member of his own foundation, but he continued to the close of his life to guide and control its affairs under powers reserved to himself in the letters patent. His diary shows that he took a large part in the life of the college.

Alleyn's first wife died in 1623. The same year he married Constance, daughter of John Donne, the poet and dean of St. Paul's. Alleyn died in Nov. 1626, and was buried in the chapel of the college which he had founded.

ALL FOOLS' DAY: see APRIL-FOOLS'-DAY.

ALL FOURS, a card game (also termed HIGH LOW JACK, OLD SLEDGE, and SEVEN UP) for two, three, or four players (in partnership). A complete pack of cards is used. All players cut for deal, the one cutting the highest card being the dealer. Ace is highest and deuce lowest. The dealer shuffles and his right-hand opponent cuts. The cards are dealt in rotation, three at a time, beginning at the dealer's left. Six cards are dealt to each player, and the next card is turned up as trump. The deal passes to the left. If an exposed card or a wrong number of cards be given a player there must be a new deal. If the dealer turns a Jack as trump he scores one point. The player at the dealer's left *stands* and makes first lead, i.e., *begs*. The dealer either gives the *beggar* one point, requiring him to lead, or *refuses*. If he refuses the trump turned is discarded face up and three added cards are given each player. If the next card differs in suit from the first one turned it becomes trump; otherwise the card turned is discarded

and three more cards are dealt to each player. The process is repeated until another suit appears or the pack is exhausted, in which case all cards are collected, shuffled, cut and redealt by the same player. The winner of one trick leads for the next one. Each player must either follow suit, trump or forfeit a point to his opponents. The highest card of the suit led or the highest trump played wins the trick. One point is scored by the one to whom is dealt the highest trump out; one point is scored by the one to whom is dealt the lowest trump out. The player of a trump may enquire if it is *high* or *low*. Jack (*Knave*) scores one point for the one winning the trick containing the Jack of trumps. Cards count one point for the player scoring most, with each 10 counting 10, each Ace 4, each King 3, each Queen 2 and each Jack 1. The claimant of cards turns each card of his tricks face up and counts aloud. A tie for cards goes to the non-dealer; as between non-dealers a tie does not score. Should two players be able to score game, precedence is given, first to the holder of *high*, next to *low*, third to Jack, last to cards. Game is 7 or 10 points, as agreed.

(E. V. S.)

ALLGEMEINE-ELEKTRIZITÄTS-GESELLSCHAFT, commonly known as the A.E.G. Prior to 1923, this was the largest electrical manufacturing concern in Germany and one of the most important industrial undertakings in the world. Since that year, however, the rapid expansion of the Siemens-Schuckert, Siemens-und-Halske group has served to relegate it to second place. The total share capital invested in the company, ordinary and preferred, was, in 1926, 156,000,000 marks, debentures and loan capital 61,760,000 marks, and reserves 16,120,000 marks, so that the total operating capital of the company was 233,880,000 marks. Its output in 1925 was given as in excess of 400,000,000 marks, and it employs about 80,000 workers.

The A.E.G. was founded by Emil Rathenau in 1883 as the *Deutsche Edison Gesellschaft für Angewandte Elektrizität* and its function at that time was merely to exploit Edison patents. Since then, working always in close association with American firms, it has been able to expand very rapidly, and its range of production covers practically all equipment used in the generation, production and consumption of electricity, while it has embarked on the manufacture of steam locomotives, steam turbines, marine engines and internal combustion engines generally. From an output of 200,000 h.p. of electrical machinery recorded in 1899, it has reached the annual quota of almost 3,000,000 h.p., while, in steam turbines alone, its effective output has risen to 800,000 h.p.

Much of this expansion has been due to the financial and administrative policy of the concern. It has applied a great part of the profits realized in production to the acquisition of controlling interests in a number of manufacturing firms both at home and abroad. These firms specialize in the production of batteries and accumulators, cables, meters and instruments, lamps and telegraphic and telephonic apparatus, and, in this way, are subsidiary to the main firm. A further development has lain in the creation of power finance corporations to finance the production, transmission and distribution of electricity in Germany and in other important markets. The electricity supply companies financed in this way constitute important customers for the products of the concern, and allow the A.E.G. to compete effectively for the supply of equipment to firms outside the range of control.

A recent survey has shown that the A.E.G. has interests in 14 manufacturing firms, four power finance corporations and 33 electricity supply companies, while it has close technical connections with the General Electric Company of America. Both these concerns work together in the development of the European market outside of the great industrial countries. The A.E.G. has also important interests among coal-mining, iron and steel, ship-building, chemical and engineering firms, especially in Germany, and has thus secured an outlet for its products. (H. Q.)

ALLIA (mod. Fosso BETTINA), a small tributary of the Tiber on the left (east) bank, about 11 m. N. of Rome. It gave its name to the terrible defeat of the Romans by the Gauls on July 18, 390 B.C. Despite objections, Livy's account, placing the battle on the left bank of the Tiber, must probably be accepted.

ALLIANCE, a city of north-western Nebraska, U.S.A., on the Burlington route; the county seat of Box Butte county. The population was 4,591 in 1920 (90% native white), and it was 6,669 in 1930 by Federal census. It has railroad shops, a cereal mill and several other industries.

ALLIANCE, a city of Stark county, O., U.S.A., on the Mahoning river, 55m. S.E. of Cleveland, about 1,080ft. above sea-level. It is served by the Pennsylvania and the New York Central railway systems. The population was 21,603 in 1920, of whom 3,026 were foreign-born whites; and was 23,047 in 1930 Federal census. The city has important manufactures, including heavy machinery, steel, automatic equipment, household appliances, office equipment, boilers and pottery. One drop-forging plant employs 2,000 men. The output of the 46 establishments within the city in 1927 was valued at \$20,445,129.

On an eminence in the south-western part of the city, two miles from the business and industrial districts is Mount Union college, a co-educational college of the Methodist Episcopal Church, which in 1926-27 had an enrolment of 769. It began as a "select school" of six pupils in 1846, and in 1858 was chartered as a college. In 1911 Scio college (1857) was merged with it. Alliance was settled and laid out in 1838; incorporated as a village in 1854, and as a city in 1888. Until 1851 it was called Freedom.

ALLIANCE, in international law, a league between independent States, defined by treaty, for the purpose of combined action, defensive or offensive, or both. Alliances have usually been directed to specific objects carefully defined in the treaties. Thus the Triple Alliance of 1688 between Great Britain, Sweden, and the Netherlands, and the Grand Alliance of 1689 between the emperor, Holland, England, Spain and Saxony, were both directed against the power of Louis XIV. The Quadruple or Grand Alliance of 1814, defined in the treaty of Chaumont, between Great Britain, Austria, Russia and Prussia, had for its object the overthrow of Napoleon and his dynasty, and the confining of France within her traditional boundaries. The Triple Alliance of 1882 between Germany, Austria and Italy was ostensibly directed to the preservation of European peace against any possible aggressive action of France or Russia; and this led, some 10 years later, to the Dual Alliance between Russia and France, for mutual support in case of any hostile action of the other powers. Occasionally, however, attempts have been made to give alliances a more general character. Thus the "Holy Alliance" (*q.v.*) of Sept. 26, 1815, was an attempt, inspired by the religious idealism of the emperor Alexander I. of Russia, to find in the "sacred precepts of the Gospel" a common basis for a general league of the European governments, its object being, primarily, the preservation of peace. So, too, by Article VI. of the Quadruple Treaty signed at Paris on Nov. 20, 1815 (which renewed that of Chaumont and was again renewed, in 1818, at Aix-la-Chapelle) the scope of the Grand Alliance was extended to objects of common interest not specifically defined in the treaties.

It was this article of the treaty of Nov. 20, 1815, rather than the "Holy Alliance," that formed the basis of the serious effort made by the great powers, between 1815 and 1822, to govern Europe in concert, which will be found outlined in the article on the history of Europe. In general it proved that an alliance, to be effective, must be clearly defined as to its objects, and that in the long run the treaty in which these objects are defined must—(to quote Bismarck's somewhat cynical dictum)—"be reinforced by the interests" of the parties concerned. Yet the "moral alliance" of Europe, as Count Nesselrode called it, though it failed to secure the permanent harmony of the powers, was an effective instrument for peace during the years immediately following the downfall of Napoleon; and it set the precedent for those periodical meetings of the representatives of the powers, for the discussion and settlement of questions of international importance, which have contributed much to the preservation of the general peace. (*See EUROPE: History.*)

In the World War the United States were "Associates," not "Allies," signifying the want of a common agreement on the objects to be attained by the war.

(W. A. P.)

ALLIARIA OFFICINALIS: *see* GARLIC MUSTARD.

ALLIBONE, SAMUEL AUSTIN (1816-1889), American author and bibliographer, was born in Philadelphia (Pa.), April 17, 1816, of French Huguenot and Quaker ancestry. He was privately educated and for many years was engaged in mercantile business in his native city. He, however, acquired a very unusual knowledge of English and American literature, and is remembered as the compiler of the well-known *Critical Dictionary of English Literature and British and American Authors* (1854-71), and of various anthologies and indexes. From 1867 to 1873, and again in 1877-79, Allibone was book editor and corresponding secretary of the American Sunday School Union; and from 1879 to 1888 he was librarian of the Lenox library, New York city. He died at Lucerne, Switzerland, Sept. 2, 1889.

See the "Memoir" by S. D. McConnell, an address delivered before the Historical Society of Philadelphia (1890).

ALLIED MARITIME TRANSPORT COUNCIL. This Council (which will be referred to below as the A.M.T.C.) was the organ through which, in the latter months of the World War, the Allied Powers decided how the merchant shipping at their disposal should be allotted among their different supply services. Throughout 1918 shipping was, in each of the Allied countries, the limiting factor in the whole of the civilian effort by which the military struggle was supported and conditioned. The authorities responsible for securing the food of their respective populations and for meeting the needs of the armies in munitions and other supplies found at this period that the primary factor in all their calculations was the amount of shipping space which they could obtain for their imported supplies or raw materials. Thus in 1918 the policy governing, in main principle, the allocation of merchant shipping determined in a very large measure the character and direction of the whole effort of the several Allied countries. It involved decisions of such intricate, far-reaching and decisive consequence that they could not be properly taken by a pure shipping authority nor indeed by any body of ministers except with the aid of a system which could give them at once access to the advice of the many authorities concerned and the means to judge between their competing claims.

We thus find that the A.M.T.C., the body of Allied ministers by whom the ultimate decisions were to be taken, was a part only, but the pivotal part, of a vast system partly national and partly international, through which the competing demands were sifted and adjusted and reduced to questions of principle, few in number but far-reaching in effect, for decision by the Council itself. This system was the counterpart in the civilian sphere of the unity of military command which was achieved at about the same time, and it was among the decisive factors in the issue of the struggle. It was different, not only in its enormous range, but in the principles of its organization, from anything previously known in administration; and it has had a profound effect on the methods and machinery by which world problems have been handled since the war. For all these reasons it deserves more attention than it has yet received both from the historian and the student of political and economic science.

The different parts of the system which were linked together by the A.M.T.C. had a separate existence, fulfilling in most cases some functions unconnected with shipping; and they are described in various other articles (*see* list at end of article). But as the A.M.T.C. was the pivotal part, it is here that we may conveniently give a brief sketch of the whole structure. Without such a general view no account of the A.M.T.C. would be intelligible, for it was essentially an instrument for linking together, for a special purpose, other authorities whose range of action extended beyond its own sphere, and except with them and through them it had no separate existence or means of action. The A.M.T.C. linked together a number of international (Allied) authorities dealing with the control of different commodities; and each of these was formed by linking together the national authorities dealing with the same commodities in the different Allied countries. The whole system was built up on the basis of national departmental control and administration, which it united and in no way replaced. We must therefore sketch, in the briefest practicable outline, the way in which the State control system grew up,

first nationally and then internationally; and for this purpose we can properly write mainly from the point of view of Great Britain, which was the principal centre of the whole Allied supply organization.

The British System of State Control.—Under the economic system in operation before the war, as now in most countries, supply is adjusted to demand by a method which is not only elastic and responsive but also automatic. Increased demand for an article pushes the price up; increased prices make it pay to produce more; they also pare off from the demand the poorer or less eager consumer. The essential characteristic of this system is that, over the whole range of human activity, needs and the means to satisfy them are adjusted without any human brain requiring to survey the system as a whole; without any attempt being made to measure competing demands in terms of either human need or public interest except so far as they are reflected in economic demand.

But for the conditions of war needs and shortage this system, independent of deliberate direction and control, proved blind and wasteful. It produced too little, it produced the wrong things, and it distributed them to the wrong people.

The State in war can order in large quantities; it can therefore dispense with many middlemen. And in war the necessities of all must have priority over the luxuries of a few. Under conditions of national shortage the criterion of effective economic demand does not secure this; with only bread enough to go round it will cause alternate surfeit and starvation. For these reasons, from the early days of the war, we find State control extending over spheres previously occupied by unfettered private enterprise. The new system was not introduced full-fledged on any general principles. On the contrary it was applied piecemeal, and often with obvious reluctance, under the compelling force of a breakdown or obvious defect of the peace system. Usually the earliest motive was to save the Treasury the expense of inflated competitive prices for war materials; then came the desire to mitigate the public indignation at similar prices for their own purchases; and lastly there was the necessity of distributing equitably what had become a bare sufficiency of the necessities of life.

90% of British Imports Under Control.—First sugar, then some two years later wheat and flour, were bought by the State. In time all the prime articles of food, both fresh and frozen meat, all cereals, oils and fats and subsidiary foodstuffs, were brought within the extending sphere of State control. And the control developed in intensity as well as range, passing from purchase to distribution, and in some cases to a detailed rationing of the individual consumer. Ultimately these activities were grouped under a central Ministry of Food. Meantime a similar process was developing in an equally wide sphere. First the manufacture of munitions and then not only all the raw materials needed for munitions, the metals and the chemicals required for explosives (coin ores, copper, zinc and spelter, lead, tin, aluminium, oils, nitrates, coal tar, etc.), but also, by a necessary consequence, all the manufactures of the country which were dependent on them, were brought within the single authority of the Ministry of Munitions. By the end of 1917 the national system of control was practically complete for both metals and food, and the two great ministries ultimately brought under their direct authority 70% of the national imports. Many of the remaining raw materials (wool, flax, jutes, hides and leather, and the connected industries) were being dealt with simultaneously, on similar principles, by the War Office. Finally, the Board of Trade, more slowly, less completely, and by more commercial methods, exercised its authority over the remaining imports (timber, cotton, paper and pulp, etc.). Ultimately 90% of the imports of Great Britain and something like that proportion of the principal productive activities of the country, were directed by the Government in the public interest. One by one the necessities of life, and of war, were brought under control, their purchase centralized, their transport allotted, their prices fixed, their consumption rationed.

It was the necessity of organizing a priority between different

services and requirements needing the same raw materials of which the full supplies available were insufficient that, to a large extent, compelled the grouping within a few great ministries which has just been described. The same necessity was constantly improving the mechanism of consultation and authority within each of these great departments which determined the proportions of the available resources to be allotted to different services and different industries. This was sufficient until a serious shortage began to be felt in the three great requirements common to them all—men, finance for the purchase of foreign supplies, and shipping to import them. This needed new machinery to decide not only within each of the ministries but between them. The system devised to allot men and to ration finance need not be described here. The central requirement, which at the most difficult period was the most serious of all, was shipping; it was upon this need that the international system under the A.M.T.C. was ultimately based.

Before describing this international development it is therefore necessary to add a note on the British control of shipping; for it was this control which the submarine made the centre of the whole system. So long as the shipping authorities were able to do their proper and normal work, that of providing the tonnage the supply services wanted, they were the servants of the supply departments. Just in proportion as submarine losses and increased requirements made it impossible for the shipping authorities to supply all the ships they were asked for, they necessarily tended to become the masters. For the allotment of the ships rested with them and that allotment set the limit to the programme of the supply department. This position only developed gradually. The British shipping department at first requisitioned only the ships needed for army and navy supplies and transport, leaving the rest for free or only partially controlled chartering. But the area extended as the stringency increased, and as a natural counterpart to the increasing control of supplies and materials by the other departments. With this extension the responsibility attaching to the allocation made by the shipping department constantly increased, till it became obviously too great to be exercised except in effective collaboration with the supply departments concerned. The successive methods by which this collaboration was attempted are described in another article (*WAR CONTROL OF SHIPPING*). Only the later developments can be noted here.

Tonnage Priority Committee.—The process by which the control of commodities was both extending and becoming grouped in a few great departments has already been described. In all these supply departments, specialized experts from the business world were incorporated in the official machine. Day by day they were testing the requirements of each industry by the criterion, not of changing market prices (which were ended by control) but of intrinsic importance in the general scheme of national policy. The Ministry of Shipping therefore, in allocating its ships, no longer had to deal with innumerable demands from hundreds of private industries, nor even directly with a score of government controls, but only with a few great ministries. In the penultimate state of this process, from Feb. 1917 till towards the end of that year, the task of balancing competing demands for shipping was facilitated by a new committee (viz., the Tonnage Priority Committee presided over by Sir Leo Chiozza Money, the under-secretary in the Ministry of Shipping) consisting of executive officials from each of the main supply departments. Finally, in the last year of the war, after the intensive submarine campaign had made the allocation of tonnage the crucial factor in all supply arrangements, the decisions involved exceeded the authority of the officials who composed the greater part of that committee, and it was succeeded by a standing committee of cabinet ministers, presided over by Lord Milner, in which both the great supply departments and the Ministry of Shipping were represented. Here at last was a mechanism—a central committee of supreme authority, having behind it centralized and co-ordinated commodity controls—by which the nation's requirements as a whole could be surveyed, adjusted and directed. The problem of national organization was solved; and with it was secured the foundation of the wider international organization which was to follow.

The International System.—For the real problem was international as well as national, and the need for common action increased with the stress. France and Italy were buying supplies in the same neutral markets and they needed transport from the same interchangeable pool of tonnage under British and Allied control.

To understand the significance of the system which gradually grew up to meet this need it is necessary to recall the normal method by which arrangements were made between countries before the war broke out. If the French Ministry of Commerce needed to arrange something with the British Board of Trade, e.g., about shipping, it transmitted its request through the British embassy in Paris, or the French embassy in London, to the British Foreign Office, who in turn sent it on to the Board of Trade. The reply would come by the same channel, so that the communication between two specialized departments would have passed four times through the hands and pens of non-specialists—or, to be exact, of those who were specialized not in shipping but in the foreign relations of the two countries. This system was based on the principle that in such discussions the primary fact was not that shipping was the subject, but that two countries were negotiating. A shipping concession on the one hand might be set off against a concession of quite another kind, perhaps political. This could only be done by those dealing with the general foreign policy of their countries.

This procedure was obviously unsuitable in war. The intricacy of the arrangements necessitated direct contact between specialized ministers and officials; the common interests of the Allies outweighed their divergencies. Gradually a system was developed of which it was the fundamental principle that a French official wanting British ships was primarily a person wanting ships from someone who could supply them and not primarily a Frenchman negotiating with an Englishman.

Commission Internationale de Ravitaillement.—This result, which will be described later, was reached through many intermediate stages. The first modest beginning was in the establishment in 1914 of a body known as the *Commission Internationale de Ravitaillement*, whose principal object was to prevent the confusion and waste caused by hundreds of Allied agents in England placing orders with private manufacturers in competition both with each other and the British War Office. This body included representatives of the Allied purchasing departments and served a useful purpose in restraining prices, distributing orders with some regard to urgency, and to some extent in pooling knowledge and experience. Essentially, however, it was not an Allied organization but a British organization to help Allied purchases. At the same time it marked a progress towards the final development. At first the British representative in the C.I.R. would collect Allied demands and then himself deal with the officials of the British departments concerned. Then he would bring the Allied supply specialist with him. Then he ceased to come himself. "Direct contact" between specialists was established in individual cases; but it still needed to be developed and organized into a system.

Shipping assistance from Great Britain to the Allies was in the first years rather improvised than organized. Appeals for help were dealt with as far as possible on their merits by the British shipping authority, a method not unjustified at first when shipping was among the least of the Allied problems. But it was obviously inadequate when the shipping situation became so serious that the allocation of tonnage was of the most vital importance to the whole of the supply arrangements. A British authority was ill-equipped to measure British against French or Italian needs.

Wheat Executive.—A further development which began, on the supply side, with the establishment in 1916 of an effective Allied committee, the "Wheat Executive," led the way to the final solution. The British Royal Commission on Wheat Supplies had found itself faced with the evils of competitive purchase in the same markets by France and Italy; and the Wheat Executive, consisting of the cereal specialists of the three countries, was formed primarily to arrange combined purchase. In this it was very successful, but it soon had other advantages. The cereal

specialists in this committee settled among themselves the proportion of the total supplies each country should have. Henceforth the Ministry of Shipping could deal with cereal demands in the mass. It no longer had to weigh France's claim for wheat tonnage against Italy's, but only the competing claim of cereals as a whole against other commodities. A little later similar committees of specialists from the Allied countries were formed for some of the "munitions" commodities; and these were gradually increased and finally grouped under an Allied munitions council of ministers.

A new impulse to developing organization on an Allied basis was given when the United States entered the war in 1917 by the formation of a council to advise as to the allocation of American Credits (see INTER-ALLY COUNCIL OF WAR PURCHASES). Had finance been more limited than ships the council might have proved the centre of the whole system; but as transport could be found only for the most vital supplies, and it was certain that for these finance would be forthcoming, the real struggle was to squeeze supply demands within the limits of the available shipping, not within those of the available finance. This meant that the shipping organization was the centre of the system; and that it was under the pressure of shipping shortage that the highly developed national and the more partially developed Allied organs were linked into one comprehensive international system. The final impetus to this development was given by the transport crisis of 1917.

Transport Crisis of 1917.—By the autumn of 1917 the pressure on shipping was greater than it had ever been; 17,000,000 tons dead-weight of the world's shipping had been lost, and less than half had been replaced. More shipping had been lost in the first ten months of this year than in the previous 30 months of the war. American building had not yet seriously begun. The prospect of her vital contribution to the armed forces meant further demands on transport. And, apart from this, the demands were constantly increasing. All the distant expeditions, except to the Dardanelles, were fully maintained, and both troops and supplies were being sent to Salonica, Mesopotamia, Palestine and East Africa. Drafts were still required from Canada, South Africa, Australia and New Zealand. The scale of the war in France grew constantly, and the development in the character of warfare involved a larger expenditure of munitions. The navies were at their maximum strength. And serious food troubles throughout the winter and spring were anticipated in Great Britain, France and Italy alike.

The strain on the shipping authorities, while there was still no comprehensive inter-Allied organization fitted to determine priority between the different supplies, was in these conditions an intolerable one. At any moment the allocation of a batch of ships to food might mean a shortage of vital munitions, an allocation to munitions might entail starvation.

But by this time the national organization in the several countries, which was the indispensable condition of the inter-Allied system, was at its full development, and in wheat and munitions partial international arrangements were already working. In Great Britain the Ministry of Shipping had full and effective control over every voyage and every cargo, and the whole system supply was centralized under the Milner Committee. A standing committee under M. Clémentel, Minister of Commerce, played a similar rôle in France. Italy's problem resolved itself practically into coal and cereals, and she had both of these as well as her shipping under complete control. Except, however, for consultation between munitions experts and the more fully developed Allied action of the Wheat Executive, these national supply systems were working with little knowledge of each other's needs. As regards most commodities there was still no means of judging fairly whether the standards of sacrifice and restriction were approximately equal or not.

The Allied Maritime Transport Council Established.—Those who realized the desperate position of shipping were convinced that it was now essential to develop and complete the system by extending Allied committees like the Wheat Executive over the whole range of supplies, and linking them up by depend-

ence for their transport upon a supreme Allied Shipping Council. On their proposal the necessary decisions were taken at the important Allied Conference which met in Paris in Nov. and Dec. 1917; and the A.M.T.C., consisting of two ministers of the three principal European Allies and two delegates from the United States of America was constituted and furnished with an executive organization.

What was the nature of this new council and of the Allied supply organization which now developed rapidly round it? It was not a supreme authority acting with a delegated power enabling it to override the governments which created it. No body of men could have been entrusted with such power, and those who at this time proposed either the appointment of a council with supreme executive power or a single economic dictator, were misled by the military analogy or ignorant of the realities of the supply situation. A single decision of such an authority, a reduction in sugar or in wheat imports for example, would affect every civilian household in the countries concerned. No cabinet could divest itself of responsibility for such decisions. The Paris Conference rightly, therefore, at the end of 1917, rejected the proposal of an "International Board with complete executive power over a common pool of tonnage."

Its Constitution.—On the other hand, if the A.M.T.C. was not in principle executive, it was in practice much more than advisory. If the first was impracticable, the second would have been useless. How could the need for urgent and desperate decisions be met by a body which, when it had itself decided, could only make recommendations to four governments and wait for their assent?

The solution of this particular dilemma was found in appointing as members of the council the ministers who in their own countries had the right to decide, and in forming the executive organization of the officials who in their own countries actually directed, or could effectively influence, the execution. This principle practically destroyed distinction between the executive and the advisory. In principle the council was advisory. But, if the British Shipping Controller agreed as a member of it to a decision involving orders to British shipping, he gave effect to it as a minister in his own department; and the same thing followed if the French Minister of Commerce agreed as a member to a decision involving a change in French supplies.

Had this principle been confined to the ministerial councils it would have represented some advance, but a quite insufficient one. Departmental conferences of ministers had often taken place before. To develop these into councils with a regular constitution and periodical meetings would have been useful, but not decisive. Ministers meet for a day or two and return. On matters of such intricate and detailed daily administration as are involved by arranging supplies in war, no such occasional meetings can resolve the difficulties of diverging national interest. The novelty of the new system consisted in the extension of this new principle, so far as was materially possible, to a series of committees of officials covering the whole range of shipping and supplies and responsible to the A.M.T.C. and two similarly formed Munitions and Food Councils.

Immediately under the A.M.T.C. was the first of these bodies, the Allied Maritime Transport Executive, of which, on the principle described above, the British member, who was the chairman, was the Director of Ship Requisitioning in the Ministry of Shipping, the French member, the influential *chef du cabinet* of the French Minister of Commerce, the Italian, an official of great influence in the Italian supply departments, while the American was one of the American members of the council. The headquarters were in London, and the staff was grouped in four national divisions under the direction respectively of the four members of the executive. The Council of ministers itself met only three times before the end of the war. But the Executive of officials met frequently, and in the long intervals between the council meetings was the instrument through which Allied co-ordination in the direction of shipping was secured.

Ultimately the whole range of imported commodities was covered by the following committees:—

Under the (Allied) Food Council:

1. Cereals (the wheat executive).
2. Oils and Seeds.
3. Sugar.
4. Meats and fats.

Under the (Allied) Munitions Council:

5. Nitrates.
6. Aircraft.
7. Chemicals.
8. Explosives.
9. Non-Ferrous Metals.
10. Mechanical Transport.
11. Steel.

And (without being grouped under a similar ministerial council):

12. Wool.
13. Cotton.
14. Flax, Hemp and Jute.
15. Hides and Leather.
16. Tobacco.
17. Paper and Pulp.
18. Timber.
19. Petroleum.
20. Coal and Coke.

It had been intended to group these last nine committees under a Raw Materials Council, but this council had not been formed when the Armistice made further organization of this kind unnecessary.

These committees secured combined Allied plans on all questions within their respective spheres on which combined action was necessary. It was only so far as their programmes needed shipping that they needed the approval of the A.M.T.C. But as the allocation of shipping was the crucial factor in all the main supply arrangements, the A.M.T.C. and its executive acquired the dominant position.

Working of the Machine.—As an example of the working of this system let us look at the duties of the most important of the Allied supply committees, the Wheat Executive, say in the spring of 1918. The committee is working, within a general programme agreed for the cereal year 1917–18. It has arranged through common agents for the provision of supplies in the United States, Canada, the Argentine and elsewhere. In contact with the shipping authorities, shipping has been sent to the loading ports. The ships are provisionally allotted for discharge in Great Britain, France and Italy; but the stocks, port facilities, etc., in each of these countries are watched daily, and the ships directed where desirable by orders sent to the ports of loading or even on arrival on the eastern side of the Atlantic.

Meantime, the Wheat Executive is negotiating with the Transport Executive as to the new programme for 1917–18. The latter, conscious of the competing claims for munitions, etc. is urging reduction. The Wheat Executive makes efforts at reduction and tries to distribute this reduction among the three countries. The margin of difference between the two executives is diminished, but not removed. An attempt is made by negotiations with the other food committees, and under the general authority of the Food Council, to balance the respective claims of cereals and other foodstuffs. The final food programme put forward by the Food Council is still in excess of what is likely to be obtained, but the difference is reduced to manageable dimensions. And the final issue is presented to the A.M.T.C., when it is practically simplified, to a decision between the competing claims of Allied food as a whole and Allied munitions.

The concluding stages of this process are best illustrated by the decisions taken at the A.M.T.C. meeting in Sept. 1918. The council, at that meeting, reviewed the whole of the prospective shipping position for 1918–19. They had before them estimates carrying the authority of the shipping experts of all the countries concerned to the effect that, after allowing for ships allotted to military expeditions and the fleets, the total imports could not exceed:

72,500,000 tons	{ for coal raw materials food munitions }	for Great Britain France Italy
--------------------	--	--------------------------------------

They decided, on the advice of the Transport Executive, that 25,200,000 tons must be allowed for coal, and 7,500,000 tons for raw materials, leaving 39,800,000 tons for food and munitions;

ALLIED MARITIME TRANSPORT COUNCIL

TABLE SHOWING THE ORGANIZATION OF INTER-ALLIED CONTROLS

1 Commodity.	2 Inter-Allied Body.	3 Method of Purchase.	4 Purchasing Body or Bodies.	5 Represented in United States by	6 Represented in certain other countries as follows:
1. Wheat.	Wheat Executive.	Single buyer.	Royal Commission on Wheat Supplies (British).	Wheat Export Company of America.	Canada: Wheat exporters. India: Controlled firms. Argentina: Controlled firms. Brazil: Controlled firms. Russia: French Commission.
2. Sugar.	Inter-Allied Sugar Programme Committee.	Single buyer in London and from International Sugar Committee in U.S.A.	Royal Commission on Sugar Supplies (British).	Representatives of Royal Commission on the International Sugar Committee.	In addition to purchases made as in column 3, the produce of some small British colonies was secured through the British Colonial Office.
3. Meats, fats, and other foodstuffs.	Inter-Allied Meats and Fats Executive.	Purchasing Organization in each procuring country aimed at.	Various.	Allied Provisions Export Committee.	British Colonies and also Argentina by the British Government.
4. Oil and oil-seeds.	Oil and Oil-seeds Executive.	Purchasing through A.P.E.C. or the govts. concerned (see cols. 4, 6).	The Executive.	A.P.E.C.	British and French Colonies by the respective governments. Brazil by agents of Wheat Commission.
5. Copper.	Copper Sub-committee, allocating powers only.	By the governments requiring supplies.	See column 3.	Purchase in U.S.A. by govts. from producers at controlled price, in account with allocation by Copper Committee.	Purchases in Spain by British Government.
6. Tin.	Tin Executive.	Supplies for France and Italy through British Ministry of Munitions.	Tin Executive.	..	The Executive generally represented in the producing countries by controlled firms.
7. Nitrate of Soda.	Nitrates Executives.	Agents on Commission.	Director of Purchases under the Executive.	..	Special agreement with the Government of Chile.
8. Rubber.	Allied Rubber Committee.	Generally by governments concerned.	Bulk of trade in hands of City merchants.
9. Wool, hair and products of wool and hair.	Wool Programme Committee (Advisory).	Australian and N.Z. clip bought by British Government, otherwise trade channels.	France partially controlled prices and quantities through Inter-departmental Wool Committee.
10. Cotton.	Cotton Programme Committee.	Usual trade channels except for Egyptian crop.	Egyptian crop bought by British and Egyptian Governments.
11. Jute, hemp and flax:- (a) Jute. (b) Hemp.	Jute, Hemp and Flax Programme Committee. Jute, Hemp and Flax Programme Committee.	Purchase by British Government from leading jute firms. British Government purchase for European Allies.	Controlled firms in Manila.
(c) Flax.	Jute, Hemp and Flax Programme Committee.	Local Allied representatives at Archangel.	Informal Inter-Allied buying arrangements at Archangel.
12. Hides and leather.	Hides and Leather Programme Committee (an Executive under consideration).	British Government purchase in India through Buying Committee of British firms in Calcutta.	Great Britain and United States control the market (chiefly India and Argentina).
13. Timber.	Timber Programme Committee and Commission Internationale d'Achats de Bois.	Purchase centralized in Italy, France, Gt. Britain, C.I.A.B. control purchasing policy.	C.I.A.B.	Purchase in United States through War Missions.	..
14. Coal.	Coal Programme Committee.	British Government controls the mines and works them through existing channels on basis of profits over period of pre-war years.	France.—Office National des Charbons, buying in United Kingdom through existing channels on a fixed basis.
15. Paper.	Paper and Paper-making Materials Programme Committee.	Central purchase of woodpulp in each country.	Centralized purchase through British Controller for European Allies suggested.	..	Italy.—All purchases made on Italian Government account. Italy.—Italian Paper Commission.
16. Petroleum.	Inter-Allied Petroleum Conference (Advisory).	By central purchase in United States of America at fixed price. Usual trade channels in other countries, subject to allocation by Conference.	..	United States Fuel Administration.	France.—Office National de la Presse.
17. Tobacco.	Tobacco and Matches Programme Committee.	No purchasing arrangements between the Allies, price control being purely national through medium of the state monopolies in France and Italy, and the Tobacco and Matches Control Board in Great Britain.

against demands of 49,000,000 (27,000,000 for food and 22,000,000 for munitions). Finally, after difficult negotiations, they allowed 22,000,000 for food and 17,800,000 for munitions. The conclusion of the Armistice a few weeks later robbed these decisions of the practical importance they would otherwise have possessed. But they illustrate the way in which the whole Allied system was by the end of the war linked together and dominated by the supreme shipping authority.

The system was, however, not fully and equally working when brought to an end by the Armistice. It was tested and working fully for food and beginning to work for munitions; but was still in its preparatory stages for miscellaneous raw materials for civilian use.

Summary of Achievements.—Imperfect as it was, however, and having to build up its elaborate organization and carry on its work simultaneously, its achievements were very striking. Though the shipping available for European supplies was some 2,000,000 tons less, the import services of France and Italy were, in 1918, for the first time put on a substantially satisfactory and substantially equal basis. Food stocks were raised to a much safer level. The Belgian relief requirements, previously in a desperate condition, were adequately met and the American troopings needs substantially assisted. These results were obtained partly through shipping economies effected by the pooling of tonnage and partly by supply economies effected by the common examination of needs and resources by the programme committees.

The fundamental principle is the *direct* contact of specialized ministers and officials of different countries effected through a regular organization whose members are grouped according to special experience and authority, not according to nationality. The national administrations now touched each other, not at one point (the Foreign Offices), but at scores (the officials engaged in the different controls) and the contact was no longer occasional but continuous. Any divergence of national interest was settled within its own sphere, and independently of differences elsewhere. Agreement once reached within each specialist committee, the further issue was not between nation and nation but between supply and supply. The Allied munitions demands were pressed as a whole with the support of the representatives of all countries against the claims of Allied food demands supported by all theirs. Thus was co-operation between the Allies at last shifted from a diplomatic to an administrative basis.

Influence of War System on Later International Organization.—The machinery so erected, and the principles of administration so developed, have left a deep impress upon subsequent organization. In the Armistice period, after some delay due to the desire of the American Government to terminate all war organizations at once, a Supreme Economic Council based on the principles described above and with a personnel very largely the same carried on the Armistice tasks of removing the blockade, bringing the German ships into use, re-allotting ships for the repatriation of troops and prisoners, for the import of raw materials required for reconstructions, arranging relief for the starving countries of Europe, and re-establishing railway transport and communications.

More important and more permanent is the influence of the same experience upon the administrative organization of the League of Nations. In spite of the obvious differences of the tasks, the student of political science will find many resemblances to the A.M.T. organization in the composition and method of working of the technical committees for finance, economics, transit, mandates, etc.—by which the Assembly and Council of the League are advised. The members of such committees regard themselves primarily as specialists in their particular subject-matter. At the same time, as they are in fact of differing nationality and know the tendencies of opinion and interest in their different countries, they afford just the kind of bridge between national opposing views which was provided by the programme committees. It was perhaps useful that all three of the European members of the A.M.T. executive joined the secretariat of the League and had a part in building up the new machinery. But essentially that machinery was constructed as it was because it is

among the fundamental principles of the League itself, first that the common interests of nations are no less important than their differences, and secondly that these common differences must be resolved by agreement and not by the overriding decision of a superior authority.

With some difference of emphasis, these were the principles which determined the Allied system; with some difference of application, the international system follows the same principles. With this system the real instrument of the League's action is not merely its permanent staff but the national organizations, public and private, which are linked together through its specialist committees and commissions. Its real executive is located not in one city but in sections, in all the main capitals of the world. Its central staff is the "coupling" which unites this intricate mechanism and enables it to achieve an international task. Geneva is not a centre of controlling power but an instrument to co-ordinate activity which is world-wide in its influence and means of action. It is an instrument, not for governing the world, but for assisting the world to govern itself in agreement and in co-operation. It permeates and transforms the policy of the world as the Allied organization permeated and transformed, without an overriding authority, the policy of the Allies. (See also SHIPPING, MINISTRY OF; WAR CONTROL OF FOOD; MUNITIONS, MINISTRY OF; WAR CONTROL OF SHIPPING; COMMISSION INTERNATIONALE DE RAVITAILLEMENT; ETC.)

BIBLIOGRAPHY.—Most of the documents concerned with the inter-Allied control of shipping and commodities were secret, and remained unpublished. A selection of the more important papers is printed in J. A. Salter, *Allied Shipping Control* (1921), in the British series "Economic and Social History of the World War" (Carnegie Endowment for International Peace). This book covers control of commodities as well as shipping, and the national and international system. The full bibliography is very voluminous. The following English books may perhaps be specially mentioned as giving a good picture of the general principles and actual working of the control system:—J. L. Garvin, *Economic Foundations of Peace* (1919); Sir L. Chiozza Money, *Triumph of Nationalisation* (1920), written from the point of view indicated in title but includes much first-hand information not otherwise available; H. D. Henderson, *The Cotton Control Board* (1922); E. M. H. Lloyd, *Experiments in State Control at the War Office and Ministry of Food* (1924); F. H. Collier, *State Trading Adventure* (1925). (A. SA.)

ALLIER, a department of France on the northern border of the *Massif Central*, formed in 1790 from the old province of Bourbonnais. Area 2,849sq.m. Pop. (1926) 370,562, a considerable decrease since 1906. It is bounded on the north by Nièvre, east by Saône-et-Loire, south-east by Loire, south by Puy-de-Dôme, south-west by Creuse, and north-west by Cher. The department is a well watered plateau, mostly 600–1,500ft. above sea-level, with heights reaching 4,239ft. in the south, in the Bois-Noirs, and forests in the northern zone. The Allier crosses the centre from south to north, the Loire forms most of the eastern boundary, and the Cher runs parallel to the Allier across the west. The heights of the Forez in the south-east and beyond get one metre of rain or more per annum and the mean winter temperature (reduced to sea level) is 39°, implying severe conditions on the heights. In the lower lands the rainfall is 600–800mm. per annum. The basin of the Allier east of its tributary the Sioule, within the department, is largely a northward continuation of the fertile Limagne of the Allier valley in Puy-de-Dôme, and is called the Limagne Bourbonnaise. It grows cereals, potatoes, and fruits, including some vines. Sheep and cattle rearing is active in the department and goats and pigs are numerous, while there are also several forests.

Carboniferous rocks outcrop along north-east to south-west lines west of the Allier, with coal seams worked for the iron and other industries at Montluçon, Commentry, Murat, etc. There are also lime and building stone quarries, so that the mineral wealth is considerable. The mineral waters of the region are widely famed, Vichy (*q.v.*), in the arrondissement de la Palisse, being the best known spa in France.

Allier is served chiefly by the Orléans and P.L.M. railways and the lateral Loire canal; the Berry canal and the canal from Roanne to Digoin touch the department. Moulins (the capital), Montluçon and Lapalisse are towns which give their names to

the usual three arrondissements of the modern system. There are 29 cantons and 321 communes. The department is also the diocese of Moulins under the archbishop of Bourges. It is in the region of the XIII. army corps and in the *académie* or educational province of Clermont Ferrand. Its court of appeal is at Riom.

Apart from Moulins (*q.v.*), it may be mentioned that the department has interesting mediaeval buildings at Souvigny (Cluniac priory 11th–15th century), St. Menoux, Ebreuil, Gannat, Veauce and Ygrande (Romanesque churches), Huriel (fine 11th century church, also castle), St. Pourçain sur Sioule (11th–18th century church). The castle at Bourbon l'Archambault (13th–15th century) was the house of the Bourbon dukes.

ALLIER (anc. *Elaver*), river of central France flowing into the Loire. Rising in the department of Lozère, its upper course is mostly through deep gorges following structural lines of weakness between the mountains of the Margeride and those of the Velay. It then traverses the basins of Langeac and Brioude, receives torrents from the mountains of Dore and Dôme, and flows through a wide but shallow channel in the fertile wheat-growing plains north of Clermont Ferrand, being joined by the Sioule above Moulins, the chief town on its banks. It reaches the Loire, 4m. W. of Nevers, after a course of 269m. (154 navigable). Its basin has an area of 6,755 square miles.

ALLIFAE (mod. *Alife*), a town of the Samnites, 15m. N.W. of Telesia, and 17m. E.N.E. of Teanum. The site of the Samnite city, which in the 4th century B.C. had a coinage of its own, is not known; the Roman town lay in the valley of the Vulturinus, and its walls (4th century A.D.) enclose a circuit of 1½m.; they have four gates at the ends of the *cardo* and *decumanus* (the main streets) by which it is still divided. Outside are preserved remains of large baths (*Thermae Herculis*) and a theatre.

ALLIGATOR, an animal so closely allied to the crocodile that the old naturalists classed them together as forming one genus. In popular speech the two are often confused (*see* CROCODILE). It differs from the true crocodile principally in having the head broader and shorter, and the snout more obtuse; in having the fourth, enlarged tooth of the under jaw received, not into an external notch, but into a pit formed for it within the upper one; in wanting a jagged fringe which appears on the hind legs and feet of the crocodile; and in having the toes of the hind feet webbed not more than half way to the tips. Two species, *A. mississippiensis* in the southern states of North America up to 12ft. in length, and the small *A. sinensis* in the Yang-tse-kiang, are still living. In Central and South America alligators are represented by five species of the genus *Caiman*, which differs from *Alligator* by the absence of a bony septum between the nostrils, and by the fact that the overlapping bony scales of the ventral armour are each composed of two bones. *C. niger* of the Amazon grows to a length of 20ft.

ALLIGATOR PEAR: *see* AVOCADO-PEAR.

ALLINGHAM, WILLIAM (1824–1889), Irish poet and man of letters, was born at Ballyshannon, Donegal, Mar. 19, 1824, and died at Hampstead, London, Nov. 18, 1889. He held various posts in the customs until 1870, when he became sub-editor of *Fraser's Magazine*, where he succeeded Froude as editor in 1874. He was a friend of D. G. Rossetti, and the 2nd edition of *Day and Night Songs* (1855) had two illustrations by Rossetti and Millais. Allingham is best remembered for many charming lyrics, some of which, like "Up the airy mountain," still find a place in anthologies.

His chief works are *Poems* (1850); *Laurence Bloomfield in Ireland* (1864); *Irish Songs and Poems* (1887); *Flower Pieces and other Poems* (1888), with two designs by D. G. Rossetti. *William Allingham: a Diary* (1907), ed. Mrs. Allingham (Helen Paterson, b. 1848) and D. Radford, contains many interesting reminiscences of Tennyson, Carlyle and other famous contemporaries. Mrs. Allingham also published a volume of letters addressed to her husband. She died in 1926 and was herself an artist of some distinction.

ALLISON, WILLIAM BOYD (1829–1908), American legislator, was born at Perry, O., on March 2, 1829. Educated at Allegheny and Western Reserve colleges, he studied law, and prac-

tised in Ohio until 1857. In that year he settled in Dubuque, Ia., where he took a prominent part in Republican politics; and in 1860 he was a delegate to the national convention at Chicago which nominated Abraham Lincoln for the presidency. In 1861 he was appointed a member of the staff of Governor Samuel J. Kirkwood (1813–1894), and was of great service in the work of equipping and organizing the Iowa volunteers. From 1863 until 1871 he served with distinction in the House of Representatives; in 1873 he was elected to the United States Senate, and was re-elected for five consecutive terms. He became one of the highest authorities on questions connected with finance, and from 1877 he was a member of the Senate committee on finance. In 1881–93, and again from 1895, he was chairman of the committee on appropriations, in which position he had great influence. He declined offers of the secretaryship of the treasury made to him by Presidents Garfield and Harrison. He was a prominent candidate for the presidential nomination in the Republican national conventions of 1888 and 1896. In 1892 he was chairman of the American delegation to the International Monetary Conference at Brussels. He died at Dubuque, on Aug. 4, 1908.

ALLITERATION, the commencing of two or more words, in close juxtaposition, with the same sound. As Milton defined rhyme to be "the jingling sound of like endings," so alliteration is the jingle of like beginnings. All language has a tendency to jingle in both ways, even in prose. Thus in prose we speak of "near and dear," "high and dry," "health and wealth." But the initial form of jingle is much more common—"safe and sound," "thick and thin," "weal or woe," "fair or foul," "spick and span," "fish, flesh or fowl," "kith and kin." The poets of nearly all times and tongues have not been slow to seize upon the emphasis which could thus be produced.

Although mainly Germanic in its character, alliteration was known to the Latins, especially in early times, and Cicero blames Ennius for writing: "O Tite tute, Tati, tibi tanta, tyranne, tulisti." We read in Chaucer:—

But of the fyr and flaumbe funeral
In which my body brennen shal to glede.

In Shakespeare:—

Full fathom five thy father lies.

In Coleridge:—

The fair breeze blew, the white foam flew,
The furrow followed free;
We were the first that ever burst
Into that silent sea.

As thus far considered, alliteration is a device wholly dependent on the poet's fancy. He may use it or not, or use it much or little, at his pleasure. But there is an extensive range of Teutonic poetry whose metrical laws are entirely based on alliteration. This, for example, is the principle on which Icelandic verse is founded; and we have a yet nearer interest in it, because it furnishes the key to Anglo-Saxon and a large portion of early English verse. Here is a passage from the famous epic *Beowulf*, alliteratively rendered by Mr. C. K. Scott-Moncrieff:—

Oft Shield of the Sheaf from scathing hordes
From many meines their mead-stoves tore;
Affrighted them the Earl since erst he was
Found unwealthy; then friendship he awaited,
Waned under the welkin, in worship throve,
Until each one of those outdwelling
Over the whale-road, must hearken to him,
Gold must give him; that was a good king.

The rhymeless lines divide into halves, and each half has normally two strong accents, irrespective of the number of syllables, all, or some, of the accented syllables being alliterated—three in each line being the usual number. Double alliteration is occasionally found. The influence of French poetry, with its definite syllabic system, worked against the continuance of this ancient recitative, and the alliterative line gradually ceased to be the vehicle of serious verse in England. But there were two great revivals, one in the 14th century, when such poems as *Pearl* (*q.v.*),

Syr Gawayne and the Grene Knight, and the *Morte Arthure* were written; the other, also in the 14th century, but quite independent, when the great poem known as *Piers Plowman* was written.

Piers Plowman, consciously archaic, suggests the Anglo-Saxon manner:—

Then gan I to meten a merveilouse swevene,
That I was in a wilderness, wist I never where;
As I behelde into the east, an heigh to the sonne,
I seigh a tour on a toft, trielich ymaked;
A depe dale benethe, a dongeon there-inne,
With depe dyches and derke and dredful of sight.

But though alliteration lingered on as a form of emphasis in popular songs, it ceased to be a regular way of English verse. Chaucer makes his Parson refer contemptuously to alliteration; but as he sneers at rhyme as well, perhaps we should not take him too seriously:—

But, trusteth wel, I am a southren man,
I can not geste "rum, ram, ruf" by lettre,
Ney, God woot, rym holde I but litel better.

For a study of alliterative verse see J. Schipper, *History of English Versification* (1910).

ALLIUM (Lat. for "garlic"), a genus of plants, of the family Liliaceae, with about 325 species (eight of which occur in Britain), found in central and south Europe, north Africa, the dry country of west and central Asia, and North and Central America. The plants are bulbous herbs, with flat or rounded radical leaves and a central naked or leafy stem, bearing a head or umbel of small flowers, with a spreading or bell-shaped white, pink, red, yellow or blue perianth. Several species afford useful foods such as onion (*Allium Cepa*), leek (*A. Porrum*), shallot or eschallot (*A. ascalonicum*), garlic (*A. ursinum*) and chives (*A. Schoenoprasum*). See CHIVES; GARLIC; LEEK; ONION; SHALLOT.

In North America there are about 70 native species, most numerous in the Rocky Mountain region and in California where the majority are found. Among some 10 species occurring in the Eastern United States and Canada are the meadow garlic (*A. canadensis*), formerly used for food by the Indians; the wild leek (*A. tricoccum*), found in rich woods; the wild chives or rush-garlic (*A. sibiricum*), found from Maine to Alaska; the nodding wild onion (*A. cernuum*), with inverted clusters of handsome flowers; and the prairie wild onion (*A. stellatum*), of rocky banks in the interior. The field garlic (*A. vineale*) of Europe, widely naturalized in meadows and pastures, is a troublesome weed tainting the flavour of butter.

ALLMAN, GEORGE JAMES (1812-1898), British biologist, was born in Cork, Ireland, and died at Parkstone, Dorset, Nov. 24, 1898. His most important work was upon the gymno-blastic hydrozoa, on which he published in 1871-72, through the Ray Society, an exhaustive monograph, based largely on his own researches and illustrated with drawings of remarkable excellence from his own hand.

ALLMERS, HERMANN (1821-1902), German writer, was born on Feb. 11, 1821, at Rechtenfleth, near Bremen. In 1858 he wrote *Marschenbuch*, in which northern lands and peoples are described. In 1860 appeared his *Dichtungen*, and nine years later his *Römische Schlendertage*, both manifesting his love of landscape imagery. The drama, *Elektra* (1872), and his somewhat stiff lyric and ballad poetry are among other writings in his *Sämtliche Werke*, 6 vols. (1891).

ALLOA, municipal and police burgh and seaport, Clackmannanshire, Scotland. It is on the north bank of the Forth, 32m. from Edinburgh by the L.N.E.R. via the Forth Bridge, and 28m. from Leith by steamer. Pop. (1931) 13,322. The L.M.S.R. enters the town from the south-west by a steel bridge across the river, and also owns a ferry to South Alloa, on the opposite shore, in Stirlingshire. Between Alloa and Stirling the stream forms the famous sinuous "links," giving a 12-mile river-course as against 6½m. by road.

Alloa makes yarn, the famous Alloa ale, spirits and yeast (Carsebridge), glass, pottery, electrical appliances, brass, iron and ships. Coal is exported and oil imported. The docks are accessible only at high water. Among the principal buildings are the fine

Gothic parish church, the town hall, including the free public library, and the museum of the Natural Science and Archaeological Society. Alloa Park, the seat of the earl of Mar and Kellie, is in the immediate vicinity, and in its grounds stand the ruins of Alloa Tower (1315), once the residence of the powerful family of Erskine, descendants of the earl of Mar.

ALLOBROGES (äl-löb'rö-gās), a Celtic tribe in the north of Gallia Narbonensis, inhabiting the low ground called the "island" between the Rhodanus, the Isara, and the Graia Alps, corresponding to the modern Dauphiné and Savoy. If the name is rightly interpreted as meaning "aliens," they would seem to have driven out the original inhabitants. Their chief towns were Vienna (Vienne), Genava (Geneva) and Culuro (later Gratianopolis, whence Grenoble). The Allobroges first occur in history as taking part with Hannibal in the invasion of Italy. After the subjugation of the Salluvii (Salyes) by the Romans in 123 B.C., the Allobroges were attacked and finally defeated (121 B.C.) at the junction of the Rhodanus and Isara by Q. Fabius Maximus (afterwards Allobrogicus). But they still remained hostile to Rome, as is shown by the conduct of their ambassadors in the Catilinarian conspiracy (63 B.C.; see CATILINE).

Holmes, *Caesar's Conquest of Gaul* (1899); G. Long in Smith's *Dict. of Greek and Roman Geography*; M. Ihm in Pauly-Wissowa's *Realencyklopädie*, i. 2 (1894).

ALLOCATUR, a law term, meaning a certificate given by a taxing master, at the termination of an action, for the allowance of costs.

ALLOCUTION, a name given to the formal addresses made by the pope to the College of Cardinals and through them to the church (Lat. *allocutio*, an address). Allocutions are usually called forth by ecclesiastical or political circumstances, and aim at safeguarding papal principles and claims. They are published by being affixed to the door of St. Peter's church.

ALLODIUM, that portion of land allotted to an individual by the chief, as representing the community, in the early Anglo-Saxon settlement of Britain. It usually consisted of the homestead, and was regarded as the property of the family. It was free from rent and services. Later, *allodium* is the regular Latin translation of bocland (*q.v.*).

ALLOMERISM, the quality of bodies by virtue of which they can change their elements and proportions while preserving their form.

ALLON, HENRY (1818-1892), English Congregational minister, was born on Oct. 13 1818, at Welton, Yorkshire. In 1844 he became co-pastor with Thomas Lewis of Union chapel, Islington. In 1852, on the death of Lewis, Allon became sole pastor, and this position he held with increasing influence till his death in 1892. Under his ministry the social aspects of church life were developed, and Union chapel became the first of what have since come to be known as institutional churches. Allon published in 1858 the original edition of his well-known *Congregational Psalmist*. For many years his collection of hymns, chants and anthems was used in hundreds of churches throughout England. Allon edited the *British Quarterly Review* from 1874 onwards, and was twice chairman of the Congregational Union.

ALLONGE, a slip of paper affixed to a negotiable instrument, as a bill of exchange, for the purpose of receiving additional endorsements for which there may not be sufficient space on the bill itself. An endorsement written on the allonge is deemed to be written on the bill itself.

ALLOPHANE, a hydrous aluminium silicate, said to be $Al_2SiO_5 \cdot 5H_2O$: it only occurs as an amorphous incrustation in thin layers on the walls of fissures and cavities in rocks, and is sometimes stained blue by copper, though usually white, yellow, or brownish. The hardness is 3 and the density 1.9.

ALLORI, CRISTOFANO (1577-1621), Italian portrait painter of the Florentine school, was the son of ALESSANDRO ALLORI (1535-1607), and was brought up and trained in art by his uncle, Angelo Bronzino (*q.v.*). Cristofano, who was born at Florence, received his first lessons in painting from his father, but becoming dissatisfied with the hard anatomical drawing and

cold colouring of the latter he entered the studio of Gregorio Pagani (1558-1605), who was one of the leaders of that later Florentine school which endeavoured to unite the rich colouring of the Venetians with the correct drawing of Michelangelo's disciples. Allori became one of the foremost of that school. His technical skill is proved by the fact that several copies he made after Correggio have been taken to be duplicates by Correggio himself. The finest of all his works is his "Judith and Holofernes," in the Pitti Palace. The model for the Judith was his mistress, the beautiful Mazzafirra, who is also represented in his Magdalene; and the head of Holofernes is generally supposed to represent his own.

ALL OR NONE, a condition set by a bidder for an issue of securities meaning that at the price he offers he wants the entire issue and cannot be held to his offer unless the issue in its entirety is awarded to him. Sellers of securities use the same term to indicate that prospective buyers must bid for, and stand ready to take, the entire issue and cannot demand a portion of it at the price offered.

ALL-OR-NONE LAW in physiology relates response to stimulus in excitable tissues. It was first established for the contraction of heart muscle by H. P. Bowditch in 1871. Describing the relation of response to stimulus, he stated, "An induction shock produces a contraction or fails to do so according to its strength; if it does so at all, it produces the greatest contraction that can be produced by any strength of stimulus in the condition of the muscle at the time." It was believed that this law was peculiar to the heart and that the other highly specialized and rapidly responding tissues—skeletal muscle and nerve—responded in a different way, the intensity of response being graded according to the intensity of the stimulus. This impression arose because nerves and muscles are composed of hundreds or thousands of individual fibres, and since some of these do not respond to a weak stimulus the total response of the organ is apparently subject to such gradation. It has now been established, largely through the work of Gotch, Lucas, Pratt, Adrian, Kato and others, that the individual fibres of both skeletal muscle and nerve respond to stimulation according to the all-or-none principle. This does not mean that the size of response is immutable. Functional capacity varies with the condition of the tissue. The response to a stimulus applied during recovery from a previous response is subnormal. The energy liberated by a muscle fibre when stimulated depends, among other things, on the mechanical conditions obtaining while the response is being evoked. But the size of response is independent of the strength of stimulus, provided this be adequate. These facts show that the functional response is essentially alike in these specialized tissues—heart, skeletal muscle and nerve; its precise nature is not known, but it resembles an explosive reaction in that it depletes for a time the available store of energy on which it depends. (A. Fo.)

ALLOSAURUS, a large carnivorous Dinosaur from North America. It was bipedal in locomotion, with very small front feet. (See DINOSAURIA; REPTILES.)

ALLOTMENT. In England, the term denotes a portion of land assigned on partition or under an inclosure award (see COMMONS); also a division of land into small portions for cultivation by a labourer or artisan at a small rent (see ALLOTMENTS and SMALL HOLDINGS). In company law, "allotment" is the appropriation to an applicant by a resolution of the directors of a certain number of shares in response to an application. The document sent to such an applicant, which announces the number of shares assigned and concludes the contract, is called a *letter of allotment* or *allotment certificate*. (See COMPANY.)

Allotment note is a writing by a seaman authorizing his employers to make an allotment of part of his wages, while he is on a voyage, in favour either of a "near" relative or of a savings bank. In the United States, the term allotment was used during the World War to denote that portion of the pay of a member of the Army, Navy or Marine Corps which was sent by direction of such person in the service to dependant relatives. In those cases, the Government paid an additional sum to such dependants as were nominated.

ALLOTMENTS. An allotment, in England and Wales, as defined by the Allotments acts 1922 and 1925, is any parcel of land above $\frac{1}{4}$ ac., but not exceeding five ac. in extent, which is cultivated as a farm or garden, or partly as a farm and partly as a garden. In other words, it is a small agricultural holding, subject to the same terms relating to notice to quit and compensation. Such allotments are almost exclusively confined to rural districts and are to be found principally in the Fen District and where the soil is suitable for market gardening. In Scotland and Ireland the proportion of allotments is relatively small (due mainly to backward legislation), but they are now governed by laws framed very largely on the English model.

The word "allotment," as popularly used, means something entirely different, and really refers to an "allotment-garden." This is defined by the act of 1922 as "an allotment not exceeding 40 poles in extent, which is wholly, or mainly, cultivated by the occupier for the production of vegetables and fruit crops for consumption by himself or his family." The overwhelming number of allotments are of this kind, and in this article the term "allotments" must be taken generally in this sense.

The Small Holdings and Allotments act, 1908, was followed by a great increase in the number of allotments. On Dec. 31, 1909, there were 58,648 allotments covering an area of 17,529 ac., increased on Dec. 31, 1914, to 130,526 allotments and 33,523 acres. During that period, land-renting associations were formed in all parts of the country with the object of procuring and managing land for their members.

Allotments for the War.—The World War changed the whole aspect of the problem. The provision of allotments had been, hitherto, largely a rural question, but the food shortage which developed as the war went on transferred the problem from the countryside to the towns and cities. Home food production on a larger scale became an imperative necessity. To ensure this, emergency legislation under the Defence of the Realm regulations was passed in 1916-17 (since withdrawn), the effect of which was to give local authorities powers for the compulsory acquisition of land for allotments. The powers granted were at first confined to the appropriation of vacant land, *i.e.*, undeveloped building sites, but were afterwards extended so that practically any land could be acquired. Hitherto, the statutory right to an allotment was confined to the "labouring population," but this limitation was withdrawn. The result was that by Dec. 31 1920, there were 1,330,000 allotments, embracing 185,000 acres. Even then there remained 44,736 unsatisfied applicants.

When the temporary allotments which had been used were taken for purposes of greater public utility, a widespread demand for alternative land on a more permanent tenure was made. This desire may be traced in a series of acts of parliament: The Land Settlement (Facilities) act, 1919; the Agriculture act, 1920; the Allotments act, 1922; the Agricultural Rates act, 1923; and the Allotments act, 1925. This legislation entitled the allotment holder, under normal circumstances, to a six months' minimum notice to quit; compensation for crops and manures when less notice was received; concessions in local rates and representation on the statutory allotments committees of local authorities. The 1925 act enabled associations to borrow from the Public Works Loan Commissioners up to two-thirds of the value of land purchased, repayment being spread over a maximum period of 35 years. Local authorities providing allotments were also empowered, if necessary, to incur a loss not exceeding a 1d. rate when action was taken under the Allotments acts. They might also obtain allotments in advance of the demand, and were compelled to consider what provision should be made for them in all schemes of town planning.

The great problem which confronts the allotment movement is insecurity of tenure. Allotment associations are helping to solve it themselves by the purchase of land where practicable, but this is impossible in congested areas where land is scarce and very expensive. Large allotment areas still exist where the tenancies may be determined by short notices to quit. An increasing number of temporary allotments have been surrendered for building purposes.

Number of Allotments.—The Ministry of Agriculture gave the figures at the end of 1923 as 1,190,000 allotments and, at the end of 1924, 1,170,000, a decrease of about 1.5%. There were 15,000 registered applicants waiting for allotments at the end of 1924. A further decrease of 64,000 was reported for 1925, and, in 1926, 27,000 more were lost, but the area was increased by 1,000 acres in that year. The Minister of Agriculture stated in the House of Commons about the middle of 1927 that the rapid decline had been almost arrested.

Allotments produce 700,000 tons of foodstuffs each year, worth, approximately, £7,000,000, and this produce not only increases the national wealth but makes a valuable contribution to the family budgets of over 1,000,000 families. From a small allotment-garden of 10 rods (just over 300 sq.yd.) it is estimated that £10 worth of vegetables is obtained during the season, when the allotment is well-cultivated and planned for rotational crops.

(1926).*

(G. W. G.)

ALLOTMENTS ORGANIZATION SOCIETY. The Allotments Organization Society and Small Holders Ltd. may be termed the residuary legatee of the late Agricultural Organization Society, and is continuing the co-operative organization of small cultivators in England and Wales, a task first undertaken by the latter body many years ago. Its principal functions are the registration of allotment and small holding associations under the Industrial and Provident Societies acts and the giving of expert advice on the leasing and purchase of land and co-operative trading. Prospective associations are supplied with model rules and when these are used the chief registrar of friendly societies reduces his fee from £10 to £3. The society acts as a central bureau of information and supplies facts and figures on the various phases of the movement of which it is the mouthpiece. It is recognized by the Ministry of Agriculture and the president, chairman and secretary have each a seat on the Ministry of Agriculture's allotments advisory committee. The society was founded in 1924, and in 1927 had affiliated 300 associations with a membership of 65,000. The society's work, so far as the small holder is concerned, consists principally of advice and guidance in the co-operative purchase and distribution of agricultural requirements, the co-operative marketing of produce and the joint ownership of implements. The chief office is at 40 Broadway, London, S.W.

ALLOTROPY was the term applied by Berzelius (1841) to the existence of a substance in two or more distinct forms. The modern tendency is to restrict the application of the term to *crystalline* forms of elements which usually have different physical but similar chemical properties, and to use the word "polymorphism" to describe the same property in compounds.

The first instance of polymorphism was noted by Mitscherlich, who in 1812 found that disodium hydrogen phosphate, Na_2HPO_4 , $12\text{H}_2\text{O}$, existed in two crystalline forms; this was followed in 1823 by the discovery of the rhombic and monoclinic forms of sulphur (*see below*). These modifications of sulphur are now said to be "allotropes" or "allotropic" forms. Among inorganic compounds which exhibit allotropy, in the older and broader sense, mention may be made of mercuric iodide; when this is precipitated by the cautious addition of a solution of potassium iodide to one of mercuric chloride, it may often be seen in a yellow form which changes almost instantly to the more stable red modification. Many organic compounds exhibit dimorphism, that is, there are two crystalline forms of the same chemical individual; for example, when para-bromoacetanilide first crystallizes from solution it does so in needles which are so felted together that they enclose the whole of the liquid and form an apparently solid mass; on standing in contact with the mother-liquor, however, they gradually change to small compact crystals, leaving the liquid quite clear. Both these cases are examples of W. Ostwald's generalization that the less stable form is produced first.

Before the various instances of allotropy are discussed in detail, some general aspects of the phenomenon must be considered. Three types of allotropy are recognized: (1) enantiotropic; (2) monotropic; and (3) dynamic.

(1) If each of two varieties involved passes reversibly into the other, at a definite temperature and pressure, and therefore exists only within a certain range of conditions, the allotropy is said to be enantiotropic. Thus, tin exists in the familiar white modification and also in a "grey" form. Above 20°C . the former is the stable modification, but below that temperature it *tends* to pass into the latter, since this is the stable form at lower temperatures. Conversely, if grey tin is gradually warmed from 0°C . it will tend to become converted into its white allotrope at 20° , which is therefore said to be the transition temperature.

(2) Monotropic allotropy occurs where the change can only be made to take place in one direction. Thus, antimony can be obtained in an "explosive" variety, which will readily pass into the ordinary stable form with the evolution of much heat, for instance, by warmth, friction or shock; but the latter form cannot be reconverted by any change of temperature or pressure into the unstable modification. This type is irreversible (*cf.* type 1).

(3) In dynamic allotropy, two forms may co-exist in a definite proportion which varies with the temperature and pressure. Alex. Smits (1903) studied the first known case of this, namely, that of sulphur. This type of allotropy has the same characteristics as dynamic isomerism (*q.v.*) or tautomerism, but it relates to elements instead of to compounds.

Since 1911 the whole question of allotropy has been studied in a new light, chiefly owing to the work of A. Smits. According to this author, the underlying cause is to be found in polymerisation, *i.e.*, that different types of molecule contain different numbers of atoms; moreover, not only is a fused element an equilibrium mixture of two or more types of molecule, but also the solid forms separating from the molten liquid are solid solutions of the different types of molecule. Further, this "inner equilibrium" may be established either so rapidly as to make the two molecular species simulate the behaviour of a single type or so slowly that the mixture behaves as if two different individuals are present.

Another general aspect of allotropy must be considered, for any two allotropic forms of an element have different energy contents (except at their transition point); the less stable, having the higher content, will evolve heat on changing into the more stable (as in the case of antimony, above); also it has a higher vapour pressure and is more soluble in any given solvent (*see PHOSPHORUS*). Moreover, this energy difference can be made to appear in an electrical form instead of a thermal form, and an e.m.f. can be developed between the two: if electrodes of grey and white tin are immersed in a conducting solution of a tin salt, according as the temperature is above or below 20° the grey or the white will be unstable and tend to go into solution and be deposited in the other (stable) form—at 20° (the transition temperature) there is no interconversion and no e.m.f. is developed.

Further, the conditions of temperature and pressure tend to influence the interconversion of allotropes according to H. Le Chatelier's principle of "mobile equilibrium," that is, the substance tends to assume that form which makes it adapt itself to the external circumstances. Thus increase of pressure favours the production of the denser form, and increase of temperature favours a change which takes place with absorption of heat, and vice versa.

Usually, the introduction of a *trace* of the form which is stable under the prevailing conditions will bring about the conversion of a supercooled liquid or metastable solid to the stable form.

Cohen has shown that most metals and alloys are in a metastable state when first formed, and as this may change slowly into a more stable state, the physical properties are somewhat variable. Aluminium, bismuth, cadmium, copper, lead, zinc, and even sodium show evidence of such changes. Mercury shows no change. For the more interesting cases of allotropy *see* CARBON; OXYGEN; PHOSPHORUS; SULPHUR; IRON; ARSENIC; SELENIUM; TIN; ANTIMONY; TELLURIUM; BORON and ICE.

The methods which have been used in determining transition points are the following: (a) *Dilatometric method*: The solid is sealed in a bulb attached to a capillary tube; the bulb is then filled with an indifferent liquid, which just reaches to the bottom of the capillary, the whole resembling a large thermometer. When the apparatus is immersed in a bath which is slowly heated the regular rise of the liquid in the capillary undergoes a sudden alteration, corresponding with a change in the solid, at the transition temperature, and then resumes its regular rise after a degree or so. (b) *Solubility measurements*: If the solubility in a given solvent is measured at a number of temperatures, the regular alteration is found to undergo a sudden change at the transition point. (c) *Thermometric method*: This method depends on the principles described in the case of iron. (d) *Optical methods*: These depend on the change of colour, crystalline form, etc. (e) *Electrical methods*: This may be illustrated by reference to the case of white and grey tin, for it is obvious that, in view of the electrical behaviour of two such electrodes (already described above), the current will undergo a reversal of sign at the transition point.

ALLOUEZ, CLAUDE JEAN (1622–1689), French Jesuit missionary to the Indians of North America, was born in St. Didier, France, on June 6, 1622. At the age of 17 he entered the Jesuit novitiate at Toulouse and, upon completion of student life at Rodez in 1656, he was appointed preacher. In 1658 he went to Canada and devoted the remainder of his life to work among the Indians. He was one of the early French Jesuits who visited the Great Lakes region. At first he served at Three Rivers and other settlements on the St. Lawrence river. In 1665 he began work among the Ottawas of Lake Superior, building in that year the first mission established among the Indians of Wisconsin. Later he founded missions among the Illinois Indians. About 1675 he settled in the Indian village of Kaskaskia and developed the mission started there by Marquette (*q.v.*). In 1679, on the approach of La Salle (*q.v.*), who was unfriendly to the Jesuits, Allouez withdrew from Kaskaskia. Thereafter he laboured chiefly among the Miamis of the St. Joseph river in south-eastern Michigan. He died in one of the Ottawa missions near the site of the present town of Niles, Mich., on Aug. 27, 1689.

Reuben Gold Thwaites (Cleveland, O., 1894–1901); Joseph Stephen La Boule, "Allouez, The Apostle of the Ottawas," *Parkman Club Publications*, No. 17 (1897); "Allouez, and His Relations with La Salle," *Hist. Soc. Wis., Proc.*, p. 168–182 (1899); Charles Wesley Mann, *Manners and Customs of the Western Indians* (1906).

ALLOWANCE, the action of allowing, or the thing allowed; particularly, a certain limited apportionment of money or food and diet (see *DIET*). Commercially "allowance" means the deduction made from gross weight of goods to make up for weight of box or package, waste, breakages, etc.

ALLOWAY, hamlet and ecclesiastical parish (pop. 797), in Ayrshire, 2½ m. south of Ayr, Scotland. It is famed as the birthplace of Burns the poet and as the scene of his "Tam o' Shanter."

ALLOXAN or **MESOXALYL UREA**, crystallizes from water in colourless rhombic prisms containing four molecules of water of crystallization. It possesses a very acid reaction; it colours the skin purple-red, and with ferrous sulphate it develops an indigo-blue coloration. It is an oxidation product of uric acid, being obtained from it by the action of cold nitric acid,

it has the structural formula $\text{CO} \begin{array}{c} \text{NH} \text{---} \text{CO} \\ \text{NH} \text{---} \text{CO} \end{array} \text{CO}$. Zinc and hy-

drochloric acid in the cold convert it into alloxantin (*q.v.*), hydroxylamine to nitroso-barbituric acid, $\text{C}_4\text{H}_2\text{N}_2\text{O}_5 \cdot \text{NOH}$, baryta water to alloxanic acid, $\text{C}_4\text{H}_4\text{N}_2\text{O}_5$; hot dilute nitric acid oxidizes it to parabanic acid (*q.v.*), hot potassium hydroxide solution hydrolyses it to urea and mesoxalic acid (*q.v.*), and zinc and hot hydrochloric acid convert it into dialuric acid, $\text{C}_4\text{H}_4\text{N}_2\text{O}_4$. Alloxan combines

with thiourea in alcoholic solution in the presence of sulphur dioxide to form pseudothiouric acid. Methyl and dimethylalloxans are also known, the former being obtained on oxidation of methyl uric acid, and the latter on oxidation of caffeine. (See *PURINES*.)

ALLOXANTIN, a product obtained by the combination of alloxan and dialuric acid. It forms small hard prisms which become red on exposure to air containing ammonia, owing to the formation of murexide (ammonium purpurate), $\text{C}_8\text{H}_4(\text{NH}_4)\text{N}_5\text{O}_6$. The formation of murexide is used as a test for the presence of uric acid, which on evaporation with dilute nitric acid gives alloxantin, when by the addition of ammonia to the residue the purple red colour of murexide becomes apparent. Alloxantin, $\text{C}_8\text{H}_4\text{N}_4\text{O}_7 \cdot 3\text{H}_2\text{O}$, may also be obtained by the action of sulphuretted hydrogen on alloxan, and it probably possesses the constitution

one of the three molecules of water being possibly constitutional. The tetra-methyl derivative, amalic acid, $\text{C}_8(\text{CH}_3)_4\text{N}_4\text{O}_7$, has been prepared by oxidizing caffeine (see *PURINES*) with chlorine water, and forms colourless crystals which are only slightly soluble in hot water.

ALLOYS, a term applied in its broadest sense to any metallic substance which is not a chemical element. If this definition is taken literally all of the metals of commerce could be regarded as alloys, since even the purest ones contain some foreign substance. It is the practice, however, to classify the metallic materials of commerce into two main groups—pure or commercially pure metals and alloys. The commercial metals are often graded with respect to the nature and amount of "impurity" present, thus giving some justification for differentiating between a "commercially pure" metal and an alloy. It is interesting to note a use of the term alloy applying to "impurities" in connection with gold. For several thousands of years gold was the most valuable metal known and any other metal mixed with it decreased the value for a given weight. The art of alloying cheaper metals with gold was practiced so fraudulently that "alloy" became associated with "impurity" or an addition which detracted from the value. This usage is standard in general English literature. It is not intended to convey the idea that the art of alloying was used formerly only to degrade or debase, but such practices became common knowledge, whereas the constructive practices did not. The great efforts in the 19th century toward modifying the properties of one metal by the addition of others served not only to popularize the benefits of alloying, but also contributed generously to the great industrial advances of the last few generations.

A definition of alloy is given by the American Society for Testing Materials, 1927, as follows: "A substance having metallic properties, consisting of two or more metallic elements or of metallic and non-metallic elements, which are miscible with each other when molten, and have not separated into distinct layers when solid." Although this definition suggests what should obtain in the molten condition—and most alloys are prepared by melting—they may be made in other ways. One of the oldest alloys is steel, composed essentially of iron and carbon. The old method of adding carbon was by heating solid iron in charcoal or in the reducing portions of wood fires, similar in principle to the present methods of adding carbon to solid iron or steel by carburization. Also alloys may be formed by mixing metal powders and heating to a temperature below the melting point, and they may be formed directly by electro-deposition. The art of preparing alloys is very old. In ancient times a number of alloys were produced by direct and simultaneous reduction of two or more metals from the ores. All of the material in a metallic substance need not be part of the alloy. For example, puddled iron or wrought iron contains some non-metallic material called slag. Wrought iron is not regarded as an alloy of iron and slag but as a relatively pure iron because the metallic constituent is relatively pure. The slag is regarded as an "inclusion." On the other hand,

non-metallic particles of cuprous oxide in copper may technically be regarded as part of the alloy because molten copper dissolves several per cent of this oxide.

Gradually the metallurgical art has advanced until nearly all of the metallic elements can be produced in a more or less pure state. Tens of thousands of combinations of 50 or more of the metallic elements with one another and with non-metallic elements have been prepared in recent times in the search for useful mixtures. It is estimated that more than 5,000 alloy compositions are in current use. This number does not include small variations such as may be expected in attempts to produce the same composition. In some respects the most common of the alloys are those used in coinage and jewellery. The so-called copper coins are really "bronze" alloys containing usually 95% copper, 4% tin and 1% zinc. Silver coins in Great Britain until 1920 were made of "sterling" silver containing 92.5% silver and 7.5% copper. All U.S. silver coins contain 90% silver and 10% copper; the five-cent piece contains 75% copper and 25% nickel. British gold coins contain 91.67% gold and 8.33% copper, whereas U.S. gold coins contain 90% gold and 10% other metals, mostly copper. Platinum, gold and silver used in the manufacture of jewellery are nearly always alloyed with other metals to modify colour, improve strength, hardness and wearing qualities or to effect economy. The purity of gold jewellery is indicated by the "karat," 24-karat being pure gold. Eighteen-karat gold containing 75% gold and 25% silver is green, 75% gold, 12.5% silver and 12.5% copper is yellow, and 75% gold and 25% copper is red. White gold can be made by the addition of nickel. These precious metal alloys comprising many specific compositions also have other important uses. For example, platinum alloys are used in thermo-couples and electric contacts of magnetos, gold alloys in dentistry and silver alloys for table ware.

Ferrous Alloys.—Alloys are classified industrially into the two main divisions, ferrous (iron base alloys) and non-ferrous. Many ferrous alloys are termed steel. (See IRON AND STEEL; STEELS, ALLOY; TOOL STEELS; STAINLESS STEELS.) Steels are by far the most important industrial alloys. They not only differ markedly in composition, but also the properties of many steels can be profoundly changed by heat treatment or mechanical working. A piece of carbon steel containing 1% carbon quenched in water from 775° C is hard and may be used for a cutting tool. It will readily machine a piece of the same steel which has been "annealed" by holding at 700° C followed by slow cooling. One steel may be magnetized by an electric circuit and become a permanent magnet. Another (iron-silicon alloy) is used in transformers partly because of its high magnetic permeability and its low magnetic hysteresis. An iron alloy containing 13% manganese and 1% carbon (Hadfield's manganese steel) is soft and non-magnetic after quenching from a high temperature, and relatively hard and magnetic when slowly cooled. Invar is an alloy containing about 64% iron and 36% nickel which does not expand when heated 200° C above room temperature. Rustless, heat-resisting and stainless qualities are imparted to iron by adding chromium, with or without nickel, silicon or aluminium, and varying the carbon content and heat treatment. Iron alloys may be made to retain high hardness at a dull red heat by suitable additions of tungsten, or molybdenum, with or without carbon, chromium or vanadium, each composition requiring a special heat treatment to develop "red" hardness. Certain of these alloys are termed "high speed" steels.

Steels are made in the form of castings, and all kinds of wrought shapes such as forgings, bars, rods, plates, sheets, structural shapes, tubing and wire. Cast irons not used in the wrought form are also included in the ferrous alloys. These are classified in three main groups: grey, white and malleable cast iron. Grey iron is essentially an iron alloy containing 2 to 4.5% carbon and sufficient silicon to cause the major part of the carbon to separate as graphite on solidification and cooling. White iron contains so little silicon or is solidified and cooled so rapidly that the carbon does not separate as graphite. It is hard and has a white fracture, whereas grey iron is relatively soft and machinable and has a grey fracture. Malleable iron is obtained by annealing white iron

in such a manner as to eliminate the carbon or more commonly to cause its separation into small and more or less spherical particles of graphite resulting in relative softness and absence of brittleness.

Non-ferrous Alloys.—Non-ferrous alloys are further classified industrially in terms of the most important metal present. Brass, for example, is termed a copper base alloy because copper is present in greater proportion than zinc. Other industrial copper base alloys are tin-bronze, silicon-bronze, aluminium-bronze, nickel-silver, copper-nickel-silicon, phosphor-bronze and cupro-nickel. (See COPPER, OUTPUT AND MANUFACTURE: *Alloys of Copper*.) Zinc base alloys are used extensively in pressure die castings. A popular alloy contains about 92 to 93% zinc, 4.5% aluminium and 3% copper, with or without a little magnesium. (see ZINC.) Lead base alloys are also used extensively in pressure die castings for bearings, acid-resisting parts, storage battery grids, etc. Plumbers' solder (*q.v.*) is an alloy containing about 67% lead and 33% tin. Type metal (*q.v.*) is also a lead base alloy containing up to 20% antimony, with or without other elements. (See LEAD, *Lead Alloys*.) Aluminium and magnesium base alloys are known as the "light alloys" because of their low specific gravity. (See ALUMINIUM, *Industrial Alloys*.) A number of nickel base alloys have found important industrial applications. (See MONEL METAL.) Among other important nickel alloys are those used as high temperature heating units in electric furnaces, thermo-couples, etc., known as nichrome, chromel, alamel, etc. These alloys all contain from 60 to 94% nickel, the other alloying elements being chromium, iron or manganese. Of particular industrial as well as scientific interest is an alloy containing 79% nickel and 21% iron, known as permalloy. This alloy when properly prepared has a low magnetic hysteresis and a very high magnetic permeability in weak fields. Its properties have made possible great advances in trans-oceanic communication by wire. (See TELEPHONE.) Tin base alloys are used for many purposes, but the principal use is in bearings. Britannia metals and babbitts are tin alloys containing antimony and copper with or without zinc, lead or bismuth. (See Plate II., fig. 7.) Ordinary pewter is a tin base alloy containing 8 to 15% lead. Stellite, a cobalt-chromium-tungsten alloy containing a small amount of carbon, is so hard that it is used as a cutting tool. It is not only hard at ordinary temperatures but possesses useful "red" hardness. (See Plate II., fig. 8.)

CONSTITUENTS OF ALLOYS

With so many alloys, each having its special properties and internal structure, and with countless possible combinations, the need for scientific as well as industrial classification is apparent. The study of the constitution and crystalline structure of alloys by means of the microscope (*q.v.*), X-ray spectrometer, thermal analysis, chemical analysis and various physical tests, has resulted in a classification of the constituents with reference to the manner of aggregation of the atoms. Three types of constituent are found: (1) Pure or substantially pure metals; (2) solid solutions; (3) chemical compounds.

Nature of Pure Metals.—A pure metal constituent is composed substantially of one kind of atom. The atoms of different metallic elements vary somewhat in effective size but they are on the order of a hundred-millionth of an inch in diameter. X-ray wave lengths are the same order of magnitude as the diameter of an atom and hence the arrangement of atoms in a crystal can be determined by diffraction of X-rays of known wave length. Although solid metals are opaque they are crystalline. The crystalline structure is described by the type and dimensions of a space lattice. A space lattice consists of a series of points in space such that every point is situated similarly to every other point. Space may be imagined as divided into cells by three sets of parallel planes, the intersections of these planes constituting the points of the space lattice. The angles which these planes make with one another and the distances apart determine the type and constants of the crystal. Most pure metals crystallize in the cubic and hexagonal systems. (See CRYSTALLOGRAPHY.) The microscope is a coarser grained tool than the X-ray spectrometer

and can only resolve particles comprising about 1,000,000,000 atoms and more. It reveals the presence of grains and grain boundaries in metals as shown in a number of the accompanying micrographs shown in Plates I. and II. Each grain in a pure metal is the same kind of a crystal but differs in orientation of the crystal axes from its neighbours. Grains may also differ markedly in size and shape.

Before making micrographs of a sample of alloy, a surface is highly polished and usually "etched" by slight chemical attack. In Plate I., figs. 1 and 10, and in Plate II., figs. 5 and 8 the different colours represent different constituents. In Plate I., figs. 9 and 12 and in Plate II., fig. 10, only one constituent is present, the different colours being due to different orientation of the grains.

Nature of Solid Solutions.—Metallic solid solutions are also crystalline. Adopting the terminology of aqueous solutions, metallic solid solutions consist of "solvent" and "solute." If, for example, a small amount of copper is alloyed with nickel, the crystalline identity of copper is lost and the nature of the nickel is changed. Copper atoms are supposed to substitute for some of the nickel atoms in the space lattice. Nickel is the solvent and copper is the solute. It so happens that nickel and copper crystallize with the same type of space lattice, and that each is soluble in the other in the solid state to an unlimited extent. Therefore in the alloy containing 50 atomic per cent of each metal no attempt is made to differentiate between solvent and solute. In other alloys of these metals the element present in the higher atomic per cent is the solvent. Although these metals crystallize with the same type of space lattice, a side of the unit cube in copper is $3.60 \text{ by } 10^{-8}$ and in nickel $3.54 \text{ by } 10^{-8}$ centimetres. The dimensions of the unit cube of the solid solution bear an approximately linear relationship to the atomic concentration, that is, the unit cube of an alloy containing 50 atomic per cent each of copper and nickel is about $3.57 \text{ by } 10^{-8}$ centimetres.

Nickel and chromium form a complete series of solid solutions but the pure metals crystallize with different types of space lattice. The solvent metal in any such solid solution alloy is the one whose type of space lattice persists. Within a certain range of composition it appears that either type of space lattice may be stable at ordinary temperatures. Nickel is the only solvent up to about 65% chromium, whereas chromium persists as the sole solvent up to only about 5% nickel. Many pairs of metals do not form solid solutions throughout the whole composition range. In the aluminium-magnesium alloys, for example, even the systems of crystallization are different, the former being cubic and the latter hexagonal. Solid aluminium dissolves only a limited amount of magnesium and vice versa. The aluminium-rich solid solutions have the same type of space lattice as aluminium, and the magnesium-rich solutions the same as magnesium. These are referred to as cases of "limited solid solubility." Not only is the solid solubility limited but the limit changes with change in temperature, usually increasing with increase in temperature, but sometimes the reverse. If a solute is present in an amount less than the solubility limit, the solution is "under-saturated," and if equal to the solubility limit it is "saturated." A solid solution saturated or nearly so at a relatively high temperature may be cooled so quickly that a "super-saturated" solid solution obtains either temporarily or more or less permanently at some lower temperatures.

An alloy composed of two elements is termed binary, one of three elements ternary, and one of four elements quaternary. Solid solution alloys may be binary or they may contain a large number of elements. Although atom substitution seems to be the rule in solid solutions, it appears that carbon atoms dissolved in solid iron occupy spaces between iron atoms.

Nature of Compounds.—Certain combinations of metals produce materials with space lattices different from that of either of the constituent elements. These materials are called, in general, compounds. Compounds have definite proportions of the elements, such as FeAl_3 , Fe_3C , CuAl_2 , Mg_2Si , etc. Usually inter-metallic compounds possess lower crystalline symmetry than the elements

from which they are formed. The constituent atoms of a compound crystal are supposed to be so fixed in their positions that different kinds of atoms are not readily interchangeable in position. It is not supposed that an oxygen atom, for example, in Cu_2O would be interchangeable with a copper atom in the Cu_2O space lattice. On the other hand, a metallic compound may be the solvent of a solid solution. Mn_3C seems to be soluble in solid Fe_3C . If so, the material would be a solid solution of manganese carbide in iron carbide. Even in this case, it is suggested that the manganese substitutes only for the iron in the space lattice, the carbon atoms being interchangeable only with one another.

PROPERTIES OF ALLOYS

Properties of Pure Metals.—The properties of an alloy depend on the properties, the proportions and arrangement of the constituents. Pure metals differ greatly in specific properties, such as hardness, melting point, electrical conductivity, ductility, density, etc. Many of these properties are transmitted to alloys of which a pure metal is one constituent, and the effect can be approximately calculated by applying the rule of mixtures. One of the outstanding characteristics of metals is their ability to be plastically deformed without rupture. This plastic deformation is possible because a portion of a crystal of a metal will slip on one or more of the crystallographic planes without rupture. In general, slip takes place the more easily the purer the given metal, and the larger the grains. Slip takes place at a much lower unit load than that which would be required to separate one plane of atoms from the other simultaneously. The total attractive forces on one of these planes would be the sum of the attractive forces of all of the atoms participating, a value termed "absolute cohesion," which is large as compared with the force required to produce slip. An automobile, weighing two tons, standing on a smooth but level pavement exerts a pressure on the pavement equal to its weight. A force of 150 lb. applied horizontally, however, may start the car in motion. This latter force would be comparable to that required to produce slippage in a metal crystal, whereas the weight of the automobile would be compared with the absolute cohesion. That the absolute cohesion is markedly greater than the unit force required to produce slip in a plastic metal crystal is clearly demonstrated by the fact that the same atoms can be differently arranged, as by reduction in grain size or by cold working, so as to greatly increase not only the force required to produce slip but also that required to produce rupture. A single crystal of iron, for example, may have a tensile strength of only 11 tons per square inch. Iron of the same purity composed of small grains may have a tensile strength of 20 tons per square inch. Another piece of iron of the same purity drawn cold through a number of dies may have a tensile strength of 40 tons per square inch. In general, the strength and hardness of a given pure metal increase with decrease in grain size, with decrease in temperature, and with increase in degree of cold work. There are some exceptions to the rule in connection with temperature change, notably in iron which undergoes an allotropic transformation at about 900°C and has a higher tensile strength in the gamma condition slightly above 900°C than in the alpha condition slightly below this temperature. Also, commercial iron and most of the ordinary steels have higher tensile strength at about 200°C than at room temperature. Because the softness of a metal is dependent on ease of slip on the crystallographic planes, any condition which interferes with the ease or freedom of this slip movement is a hardening factor. The factors favouring high plasticity are generally those which favour softness, namely large grain size, freedom from cold work and high temperature.

Properties of Solid Solutions.—The properties of very dilute solid solutions are usually quite similar to the properties of the commercially pure solvent metals themselves. The departure from similarity takes place gradually as the amount of solute increases, and obtains to a different degree for equal amounts of different solutes. Pure metals freeze or melt at a constant temperature, whereas most solid solution alloys freeze or melt throughout a range of temperature. Solid solution alloys are harder and

in general less plastic than the solvent metal. The electrical conductivity is less than that of the solvent metal. In fact, this property changes to a much greater extent than would be indicated by the law of mixtures. The hardness also disobeys the law of mixtures. For example, tin is much softer than copper, but a solid solution of tin in copper is considerably harder than the copper itself. The temperature coefficient of electrical resistivity of solid solution alloys is usually lower and sometimes markedly lower than in the pure metals. Certain solid solution alloys possess a zero or even slightly negative temperature coefficient. Also, the thermo-electric force of a solid solution is often markedly different from that of the solvent metal.

Properties of Compounds.—Compounds, and particularly inter-metallic compounds, are characterized by relatively high hardness and low plasticity. Metallic compounds are very important constituents in alloys from the standpoint of increasing hardness, decreasing grain growth and particularly for the purpose of maintaining strength of alloys at high temperatures. Each compound has its specific properties, some having high melting point, some low, some with high hardness, some with low hardness, a few with considerable plasticity, but many with practically no useful plasticity.

Proportions and Arrangements of Constituents.—Certain properties of alloys, such as density and resistance to penetration by X-rays, may be determined by the proportions and specific properties of the various constituents. Many of the properties, however, depend to a greater or less extent on the *arrangement* as well as the proportions. In an alloy containing more than one type of constituent, the most important thing to be considered is which constituent possesses continuity. This is particularly important if the different constituents vary considerably in hardness and plasticity.

The importance of the degree of refinement of the separate constituents has been demonstrated forcibly in recent years. In many alloys the proportions of the constituents may be changed by heat treatment, and at the same time the manner of aggregation may be changed. Using the copper-Ni₂Si system as an example, the alloy containing 6% Ni₂Si will consist largely of solid solution of nickel and silicon in copper after quenching from 900° C. The Brinell hardness is about 70. By heating to 525° C a short time a considerable portion of the nickel and silicon precipitate in submicroscopic particles of Ni₂Si, increasing the hardness to above 200. During this heating period the hardness rises for a certain length of time, reaches a maximum and eventually may decrease somewhat to approximately a constant value. These changes in hardness are associated with change in amount and size of the hard particles of Ni₂Si. There appears to be an average size of precipitated particle which produces maximum hardening effect for a given quantity of the constituent. In this condition, referred to as "critical dispersion" for maximum hardness, the particles are too small to be resolved with a microscope.

The above is an example of what has become a common practice in commercial selection and heat treatment of a number of alloy types. The high temperature step in the heat treatment is referred to as the *solution treatment*, and the low temperature step as *precipitation treatment*. Many alloys have been found to exhibit changes in properties and structure when subjected to this type of heat treatment. The alloy compositions must be carefully selected with reference to solubility limits of solid solutions, change of solubility with change in temperature, and the temperature and time of the heat treatment must be varied to suit the particular alloy. Some alloys, for example, duralumin and lead-antimony alloys, need not be given an "artificial" precipitation heat treatment because the precipitation takes place spontaneously at room temperature. Other alloys must be heated above room temperature in order to cause precipitation. These changes in particle size and in the amount of solute in a solid solution are possible in alloys only because of diffusion in the solid state. Diffusion is supposed to occur by migration of solute atoms in the grain boundaries and in the space lattice of the solvent. Rapid diffusion is favoured by high temperature and at certain

relatively low temperatures, different for different alloys, diffusion may, for practical purposes, be considered not to take place. Also diffusion is more rapid along grain boundaries than through the crystalline grains themselves.

CONSTITUTION DIAGRAMS

The number, composition and proportions of the constituents in equilibrium at any given temperature, and changes due to change in temperature may be represented graphically in a constitution diagram. Such diagrams present only equilibrium conditions and are not concerned with the arrangement of the constituents. A binary alloy diagram may be represented on a two dimensional chart, as in fig. 1, but ternary alloy systems require three dimensions for suitable graphic representation. Complete graphic representation of the constitution becomes difficult if not hopeless in alloys containing four or more components. Plane charts, however, within restricted composition limits, particularly

FIG. 1.—CONSTITUTION DIAGRAM SHOWING NUMBER, COMPOSITION AND PROPORTION OF THE CONSTITUENTS IN EQUILIBRIUM AT ANY GIVEN TEMPERATURE, AND CHANGES DUE TO CHANGES IN TEMPERATURE

when only two of the components are allowed to vary at one time, are exceedingly useful even with complex alloys. In alloy systems each physically distinct and homogeneous part is called a "phase," and the chemical elements or compounds which participate in the equilibria are called "components."

In fig. 1, the liquid alloy is one phase, the solid aluminium or aluminium-rich solid solution another, and the solid compound CuAl₂ another. Aluminium and CuAl₂ are the components. In the whole system other compounds are formed and the elements, aluminium and copper, may be regarded as the components. The *liquidus* is the line or curve representing the beginning of solidification, and the *solidus* represents the end of solidification on cooling. In some alloy systems the liquidus passes through a minimum temperature, coinciding with the solidus at a certain composition. If the solidified alloy having such a minimum freezing point shows the presence of at least two phases under the microscope it is called a *eutectic* alloy. Eutectics may be binary, ternary, etc., in accordance with the number of phases present. Eutectic alloys freeze and melt at a constant temperature rather than through a temperature range, and the eutectic composition does not, except by coincidence, represent simple whole number proportions of the elements.

The properties and structures of alloys may be profoundly changed by mechanical working and by heat treatment. Certain of these changes in structures are indicated in the accompanying micrographs and the corresponding changes in properties are indicated in the titles.

ALLOY STEELS: see STEEL (ALLOYS).

ALLPORT, SIR JAMES JOSEPH (1811-1892), English railway manager, was, for 20 years onwards from 1853, the general manager of the Midland railway. He is remembered as the pioneer of cheap and comfortable railway travelling. He was the first to appreciate the importance of the third-class passenger as a source of revenue, and in 1872 he inaugurated the policy, subsequently followed by all the important railways of Great Britain, of carrying passengers in well-fitted third-class carriages at the rate of a penny a mile. He was also the first to introduce the Pullman car on British railways. Allport was knighted in 1884. He died in London on April 25, 1892.

ALLPORT, SAMUEL (1816-97), English petrologist, was born in Birmingham Jan. 23, 1816, and died at Cheltenham July 7, 1897. He was a pioneer in microscopic petrology. The basalts of south Staffordshire, the diorites of Warwickshire, the phonolite of the Wolf Rock (to which he first directed attention), the pitchstones of Arran and the altered igneous rocks near the Land's End were investigated and described by him during the years 1869-79 in the *Quarterly Journal of the Geological Society* and in the *Geological Magazine*.

ALL RISKS INSURANCE: see INSURANCE, MISCELLANEOUS.

ALL SAINTS BAY or **BAHIA DE TODOS OS SANTOS**, a land-locked bay and natural harbour on the eastern coast of Brazil about 738m. (1,187km.) north-east of Rio de Janeiro. The bay is about 20m. wide and 23m. long with an entrance from the Atlantic about 2m. broad. The channel leading through this entrance is rather circuitous and varies with the seasons of the year. Detached breakwaters, one 1,300yd. long and another about 1,000yd. long, cause the water of the bay to be less disturbed by the winds. The controlling depth of the channel varies from 26 to 33 feet. On entering All Saints bay from the Atlantic, one is impressed with the beauty of the bay and the hills rising from the water's edge. On the western side of the peninsula separating the bay from the Atlantic, in 13° S. and 38° 30' W., is Bahia or São Salvador (pop. 350,000), an important seaport and capital of the State of Bahia.

ALL SAINTS, FESTIVAL OF (ALL HALLOWS, HALLOWMASS), a feast of the Church celebrated on Nov. 1 in honour of all saints, known or unknown, as a festival of the first rank, with vigil and octave. The first trace of a general commemoration of martyrs is in Antioch on the Sunday after Pentecost; Chrysostom (d. 407) also refers to the custom. At Rome the feast of St. Mary ad Martyres was instituted on May 13, 609 or 610, when Boniface IV. dedicated the Pantheon to the Blessed Virgin and all martyrs. Gregory III. (731-741) dedicated an oratory in St. Peter's to all saints, and fixed the anniversary for Nov. 1. This observance was extended by Gregory IV. (827-844) to the whole Church; the octave was added by Sixtus IV. (1471-84). At the Reformation the festival was retained in the calendars of the Church of England and many of the Lutheran Churches; in the latter, however, it has fallen into complete disuse.

ALL SOULS' DAY, the day (Nov. 2 or, if that be a Sunday or festival of the first class, Nov. 3) set apart in the Roman Catholic Church for commemoration of the faithful departed; a custom based on the doctrine that souls which at death are not yet sufficiently purified to be fit for the Beatific Vision may be helped by the prayers of the faithful here on earth. The practice of devoting certain days to intercession for particular groups of the dead is of great antiquity; but the institution of this feast of general intercession is due to Odilo, abbot of Cluny (d. 1048), who ordered its observance in the Cluniac monasteries. It spread thence among other congregations, and became practically universal before the end of the 13th century. It was abolished in the Church of England at the Reformation, but has been revived in "Anglo-Catholic" churches. Among continental

Protestants its tradition has been more tenaciously maintained, especially in Saxony, where, though its ecclesiastical sanction has long since lapsed, its memory survives strongly in popular custom. As in France people of all ranks and creeds decorate the graves of their dead on the *jour des morts*, so in Germany the people stream to the graveyards once a year with offerings of flowers.

Certain popular beliefs connected with All Souls' Day are of pagan origin and immemorial antiquity. In many Catholic countries the dead are believed by the peasantry to revisit their homes on All Souls' night and partake of the food of the living. In Tirol cakes are left for them on the table. In Brittany the people flock into the cemeteries at nightfall to kneel bare-headed at the graves of their loved ones, and to pour libations of milk or holy water on the tombstones, and at bedtime supper is left on the table for the dead.

ALLSPICE, the dried unripe berry of the pimento or allspice tree (*Eugenia pimenta* or *Pimenta officinalis*) of the myrtle family. The tree, which attains a height of 40ft., is native to Central America and to the West Indies where it is also cultivated. This highly aromatic spice, widely used in cookery and in medicine, is supposed to combine the flavour of cinnamon, nutmeg and cloves, whence its name. The name is applied also to other aromatic shrubs, especially to the Carolina allspice (*Calycanthus floridus*), a handsome flowering shrub, native to the south-eastern United States and often cultivated in England; to the Japanese allspice (*Chimonanthus fragrans* or *Meratia praecox*), native to Eastern Asia and planted for ornament in England and the United States; and to the wild allspice or spicebush (*Benzoin aestivale*), a lauraceous shrub of eastern North America, with aromatic berries, reputed to have been used as a substitute for spice.

ALLSTON, JOSEPH (c. 1779-1816), American planter and governor of South Carolina, was born probably in All Saints' parish, S.C., about 1779. He was educated at Princeton but left in his senior year without graduating and studied law in the office of Edward Rutledge. He was elected a member of the lower house of the South Carolina legislature in 1802, and continued to serve until 1812, being speaker from 1805 to 1809. In 1812 he was elected governor and his administration, 1813-15, was noted for its energetic support of the War of 1812. In 1801 Allston married Theodosia Burr (q.v.), brilliant daughter of Aaron Burr (q.v.). Through this marriage Allston was drawn into a minor connection with the so-called "Burr Conspiracy," and the fact seriously hampered his later political career. It was but natural that he should have aided Burr during the trial to establish his innocence, and it has been established that he was the author of the pamphlet *Agræstis* which then appeared. Allston's only child died in 1812 and in 1813 Theodosia was lost at sea. Allston, himself of frail health, survived these tragedies but a few years, dying on Sept. 10, 1816.

ALLSTON, ROBERT FRANCIS WITHERS (1801-1864), American planter and governor of South Carolina, was born in All Saints' parish, S.C., on April 21, 1801. He was educated at the West Point academy and upon his graduation in 1821 he was appointed a lieutenant in the Coast Survey. He aided in the surveys of Plymouth and Provincetown harbours in Massachusetts and the entrance to Mobile bay. In 1822 he resigned his commission in order to manage the plantation of his widowed mother. He was elected in 1823 to the office of surveyor general of South Carolina which he held for two terms. In 1828 he was elected to the lower house of the legislature. He was re-elected in 1830, and in 1832 he was elected to the State senate, to which he was regularly returned for 24 years. He served from 1847 to 1856 as that body's presiding officer. During the nullification episode he was made colonel of militia. He was a supporter of the States' rights doctrine but believed, nevertheless, that closer co-operation must be instituted between the Southern States. He was elected governor for the term 1856-58, and did much during his administration for the development of agriculture and the backward public school system.

Because of his energy and his scientific knowledge of agriculture Allston rose to a high position among Southern planters. His

was one of the last great rice plantations in the low lands, and he did much in an engineering way in the draining and reclaiming of swamp country. He published two treatises, *A Memoir of the Introduction and Planting of Rice in South Carolina* (1843), and *An Essay on Sea Coast Crops* (1854), both of which were authoritative works and of great influence among the planters of the time. He died on April 7, 1864.

His daughter, Mrs. E. W. A. Pringle, gives an intimate account of him in *Chronicles of Chicora Wood* (1922).

ALLSTON, WASHINGTON (1779–1843), American historical painter and poet, was born Nov. 5, 1779, at Waccamaw (S. C.), where his father was a planter. He graduated at Harvard in 1800, and for a short time pursued his artistic studies at Charleston with Edward Greene Malbone (1777–1807), the miniature painter, and Charles Fraser (1782–1860). With the former, in 1801, he went to London, and entered the Royal Academy as a student of Benjamin West, with whom he formed a lifelong friendship. In 1804 he went to Paris, and, after a few months' residence there, to Rome, where he spent the greater part of the next four years. During this period he became intimate with Coleridge and Thorwaldsen. From 1809 to 1811 he resided in his native country, and from 1811 to 1817 he painted in England. After visiting Paris a second time, he returned to the United States, and practised his profession at Boston (1818–30), and afterwards at Cambridge (Mass.), where he died July 9, 1843. He was elected an associate of the Royal Academy in 1819. In colour and the management of light and shade Allston closely imitated the Venetian school, and he has hence been styled the "American Titian." Many of his pictures have biblical subjects, and Allston himself had a profoundly religious nature. His first considerable painting, "The Dead Man Revived," executed shortly after his second visit to England, and now at the Pennsylvania Academy of Fine Arts in Philadelphia, gained a prize of 200 guineas. In England he also painted his "St. Peter Liberated by the Angel," the remarkable canvas, "Uriel in the Sun," "Jacob's Dream" (at Petworth) and "Elijah in the Wilderness." To the period of his residence in America belong "The Prophet Jeremiah" (at Yale), "Saul and the Witch of Endor," "Miriam," "Beatrice," "Rosalie," "Spalatro's Vision of the Bloody Hand," and the vast but unfinished "Belshazzar's Feast" (in the Boston Athenaeum), at which he was working at the time of his death. As a writer, Allston shows great facility of expression and imaginative power. Coleridge (a portrait of whom by Allston is in the National Portrait Gallery) said of him that he was surpassed by no man of his age in artistic and poetic genius. His literary works are—*The Sylphs of the Seasons and other Poems* (1813), where he displays true sympathy with nature and deep knowledge of the human heart; *Monaldi* (1841), a tragical romance, the scene of which is laid in Italy; and *Lectures on Art*, edited by his brother-in-law, R. H. Dana and the novelist (1850).

See J. B. Flagg's *Life and Letters of Washington Allston* (1892).

"ALL THE TALENTS," MINISTRY OF, the name given to the coalition government which came into office after the death of Pitt (Jan. 23, 1806). Lord Grenville was at the head of the ministry, which included Fox and Lord Sidmouth. Fox died on Sept. 13; and after a disastrous year in which Napoleon reached the summit of his power, Grenville resigned (March 18, 1807) rather than agree to George III.'s unconstitutional demand that the ministers should undertake never again to approach him on the subject of concessions to Roman Catholics. It was due to the Ministry of all the Talents that the bill for the abolition of the slave trade was passed on March 25, 1807.

ALLUVION, a word taken from Roman law, in which it was one of the examples of *accessio*, that is, acquisition of property without any act being done by the acquirer. It signifies the gradual accretion (*q.v.*) of land or formation of an island by imperceptible degrees. If the accretion or formation be by a torrent or flood, the property in the severed portion or new island continues with the original owner until the trees, if any, swept away with the island take root in the ground. Alluvion never attached at all in the case of *agri limitati*; i.e., lands belonging to the State and leased or sold in plots. Dig. xli. 1, 7,

is the main authority. English law is in general agreement (except as to *agri limitati*) with Roman, as appears from the judgment in *Foster v. Wright*, 1878, 4 C.P.D. 438. The Scottish law, as laid down by the House of Lords in *Earl of Zetland v. Glover Incorporation*, 1872, L.R. 2 H.L., Sc., 70, is in accordance with the English. (See WATER RIGHTS.)

ALLUVIUM, the material deposited by rivers (see the general article GEOLOGY). It is usually most extensively developed in the lower part of the course of a river, forming flood-plains and deltas, but may be deposited at any point where the velocity of a river is checked; for example, where it runs into a lake. Alluvium in the true sense consists mostly of silt, sand, and gravel, without much true clay; it often contains a good deal of organic matter and therefore yields very fertile soils. Some of the great alluvial deposits of the world are: the flood-plain of the Mississippi, the deltas of the Nile, of the Ganges and Brahmaputra, and of the Hwang Ho in China. Owing to elevation of the land and consequent deepening of the river channel, patches of alluvium are often left forming terraces on the sides of valleys. On such terraces much of London is built. In some regions alluvial deposits contain gold, platinum or gem-stones, and the greater part of the world's supply of tin ore comes from similar sources.

(R. H. RA.)

ALLYL ALCOHOL, a colourless mobile liquid of pungent smell, boiling at 97°C. Its chemical formula is C_3H_5OH or $CH_2:CH-CH_2OH$. It is an unsaturated primary alcohol occurring in very small quantities in wood spirit. It may be prepared by heating glycerin with oxalic acid and a little ammonium chloride to 260°C. In this reaction glycerol monoformin is produced as an intermediate product, but is decomposed as the temperature rises:—

Being unsaturated allyl alcohol combines readily with the halogens. Oxidation by strong oxidizing agents converts it successively into its aldehyde, acrolein, and into acrylic acid. By gentle oxidation with potassium permanganate, it may be converted into glycerin (see CHEMISTRY: Organic).

ALMA, a city of Gratiot county, Mich., U.S.A., on the Pine river, 37m. W. of Saginaw, almost exactly in the geographical centre of the lower peninsula. It is served by the Ann Arbor and the Pere Marquette railways. The population increased between 1910 and 1930 from 2,757 to 6,734. It has good water-power. Its factories make automobile steering wheels, motor-trucks, beet sugar, cement blocks, and pickles. It is the shipping point for a fertile farming and grazing district, and is the seat of Alma college and the State Masonic home. The city was incorporated in 1905, and adopted a commission-manager form of government in 1919.

ALMA, a river of Russia, in the south-west of the Crimea, entering the Black Sea 17m. N. of Sevastopol. It gives its name to a famous victory gained over the Russians, on Sept. 20, 1854, by the allied armies in the Crimean War (*q.v.*). The south bank of the river is bordered by a long ridge, which becomes steeper as it approaches the sea, and upon this the Russians, under Prince Menshikov, were drawn up, to bar the Sevastopol road to the allies, who under General Lord Raglan and Marshal St. Arnaud approached from the north over an open plain. The Russian commander massed his troops in heavy columns after the fashion of 1813, and drew in his left wing so that it should as far as possible be out of range of the allied men-of-war, which were sailing down the coast in line with their land forces. The allied generals decided that the French (right wing) and the Turks should attack Menshikov's left, while the British, further inland, were to assault the front of the Russian position. The forces engaged are stated by Hamley (*War in the Crimea*) as, French and Turks, 35,000 infantry, with 68 guns; British, 23,000 infantry, 1,000 cavalry and 60 guns; Russians 33,000 infantry, 3,800 cavalry and 120 guns; by the Austrian writer Berndt (*Zahl im Kriege*) the allied forces are reckoned at 57,000 men with 108 guns, and the

Russians at 33,600 men with 96 guns. The French advance met at first with little opposition, and several divisions scaled the cliffs of the lower Alma without difficulty. Menshikov relied apparently on being able to detach his reserves to cope with them, but the assailants moved with a rapidity which he had not counted upon, and the Russians only came into action piecemeal in this quarter. Opposite the British, who as usual deployed at a distance and then advanced in long continuous lines, the Russians were posted on the crest of a long glacis-like slope, which offered but little dead ground to an assailant. The village of Burluk, and the vineyards, which bordered the river, were quickly cleared by the British skirmishers, and the line of battle behind them crossed though with some difficulty. On emerging from the cover afforded by the river-bed the British divisions, now crowded together, but still preserving their general line, came under a terrible fire from heavy guns and musketry. The enemy's artillery was three hundred yards away, yet the British pressed on in spite of their losses, and as some of the Light Division troops reached the "Great Battery" the Russians hurried their guns away to safety. In the meantime, on both sides of this battery, the assailants had come to close quarters with the Russian columns, which were aided by their field guns. A brave counter-attack was made by the Russian Vladimir regiment, 3,000 strong, against the troops which had stormed the great battery, and for want of support the British were driven out again. But they soon rallied, and now the second line had crossed and formed for attack. The Guards brigade attacked the Vladimir regiment, and on the left the Highland brigade and the cavalry moved forward also. Some of the field artillery, which had now crossed the Alma, fired steadily into the closed masses of the Russian reserve, and the Vladimir regiment lost half of its numbers under the volleys of the Guards. The French were now severely pressing the Russian left, and one-third of Menshikov's forces was drawn into the fight in that quarter. The success of the frontal assault had dispirited the remainder of the defenders, and Menshikov drew off his forces southwards. He had lost 5,700 men (Berndt and Hamley). The British had about 2,000 killed and wounded; the French stated their losses at 1,340 men.

ALMA ATA (formerly *Vyernyi*). (1) A town which is the capital of the Dzhetysyisk province of the Autonomous Kazak (Kirghiz) S.S.R., Pop. (1926) 45,379. It was founded as a fortified settlement by the Russians in 1855, but is now important commercially, and may become more so if the projected railway links with the Trans-Siberian and Orenburg-Tashkent railways are built. (2) A district round the town, area 72,052sq.km. Pop. (1926) 370,806, on the northern slopes of the beautiful Khungai Ala Tau mountains, watered by streams which run through the fertile loess area below to Lake Balkash. The climate and soil are favourable to vine and fruit cultivation.

ALMACANTAR (also written **ALMUCANTAR**), an astronomical term for a small circle of the sphere parallel to the horizon; when two stars are in the same almacantar they have the same altitude. The term is also given (1880) to instruments of a pattern invented by S. C. Chandler to determine the latitude or the time by observing the times of transit of stars across a fixed almacantar.

ALMACK'S, formerly the name of a famous London club and assembly rooms. The founder is usually said to have been one Macall, or McCaul, of which name Almack is an anagram. In 1764 he founded a gentlemen's club in Pall Mall, where the present Marlborough Club stands. It was famous for its high play. In 1778 it was taken over by one Brooks, and established as Brooks's Club in St. James's Street, where it still exists. In 1765 Almack built a suite of assembly rooms in King Street, St. James's. At his death in 1781 they were left to his niece Mrs. Willis, and as "Willis's Rooms" lasted till 1890, when they became a restaurant; but as "Almack's" they ceased in 1863. A 20th century club has since adopted the old name.

ALMADÉN or **ALMADEN DEL AZOGUE**, a town in Spain, province of Ciudad Real. Pop. (1920) 9,829. Almadén (Ar. almadén, the mine) has been for centuries the principal centre for the famous ores of mercury, impregnating the quartzite of certain

ridges between the Sierras of Chillón (N.) and Cordoneros (Alcudia) (S.). The *Sisapo* of the Romans lay in the same neighbourhood. Almadén and Adria (Southern Austria) were the chief sources of mercury till New Almadén (California) was opened up (1853-57). They were long worked by convicts owing to the unhealthy atmosphere and exemption from military service is granted to miners who have worked at Almadén for two years.

See *Minas de Almadén* (Madrid, 1926), guide-book, XIVth. Int. Congr. of Geol., with diagram showing entire production of the mines since the 15th century.

ALMAGEST, the famous treatise on astronomy by Ptolemy in the 2nd century A.D. Besides the exposition of the Ptolemaic theory of the heavens, it contains an important catalogue of the places of 1,080 stars. (See **PTOLEMY**.)

ALMAGRO, DIEGO DE (c. 1470-1538), Spanish *conquistador*; a foundling, born in Spain about 1470. In 1526, he contracted with Francisco Pizarro (*q.v.*) an equal partnership in the conquest of Peru. Pizarro immediately assumed the precedence; Almagro was delegated to provide reinforcements and supplies. He arrived in Peru in 1532, was present at the death of Atahualpa (*q.v.*), assisted in the capture of Cuzco (Nov., 1533) and in 1534 was sent to stop Pedro de Alvarado's march upon Quito, from the coast. Receiving, in 1535, a royal grant of 200 leagues, south of Cuzco, he undertook the terrible march into Chile, but finding no gold, returned and seized Cuzco. In the battle of Abancay (1537), he destroyed Pizarro's army, but allowing himself to be drawn into a truce, was completely routed by Hernando Pizarro at Las Salinas (April 1538) and captured. Convicted by his captor of treason against the crown, in July, 1538, he was garrotted in his prison, and beheaded in the public square of Cuzco.

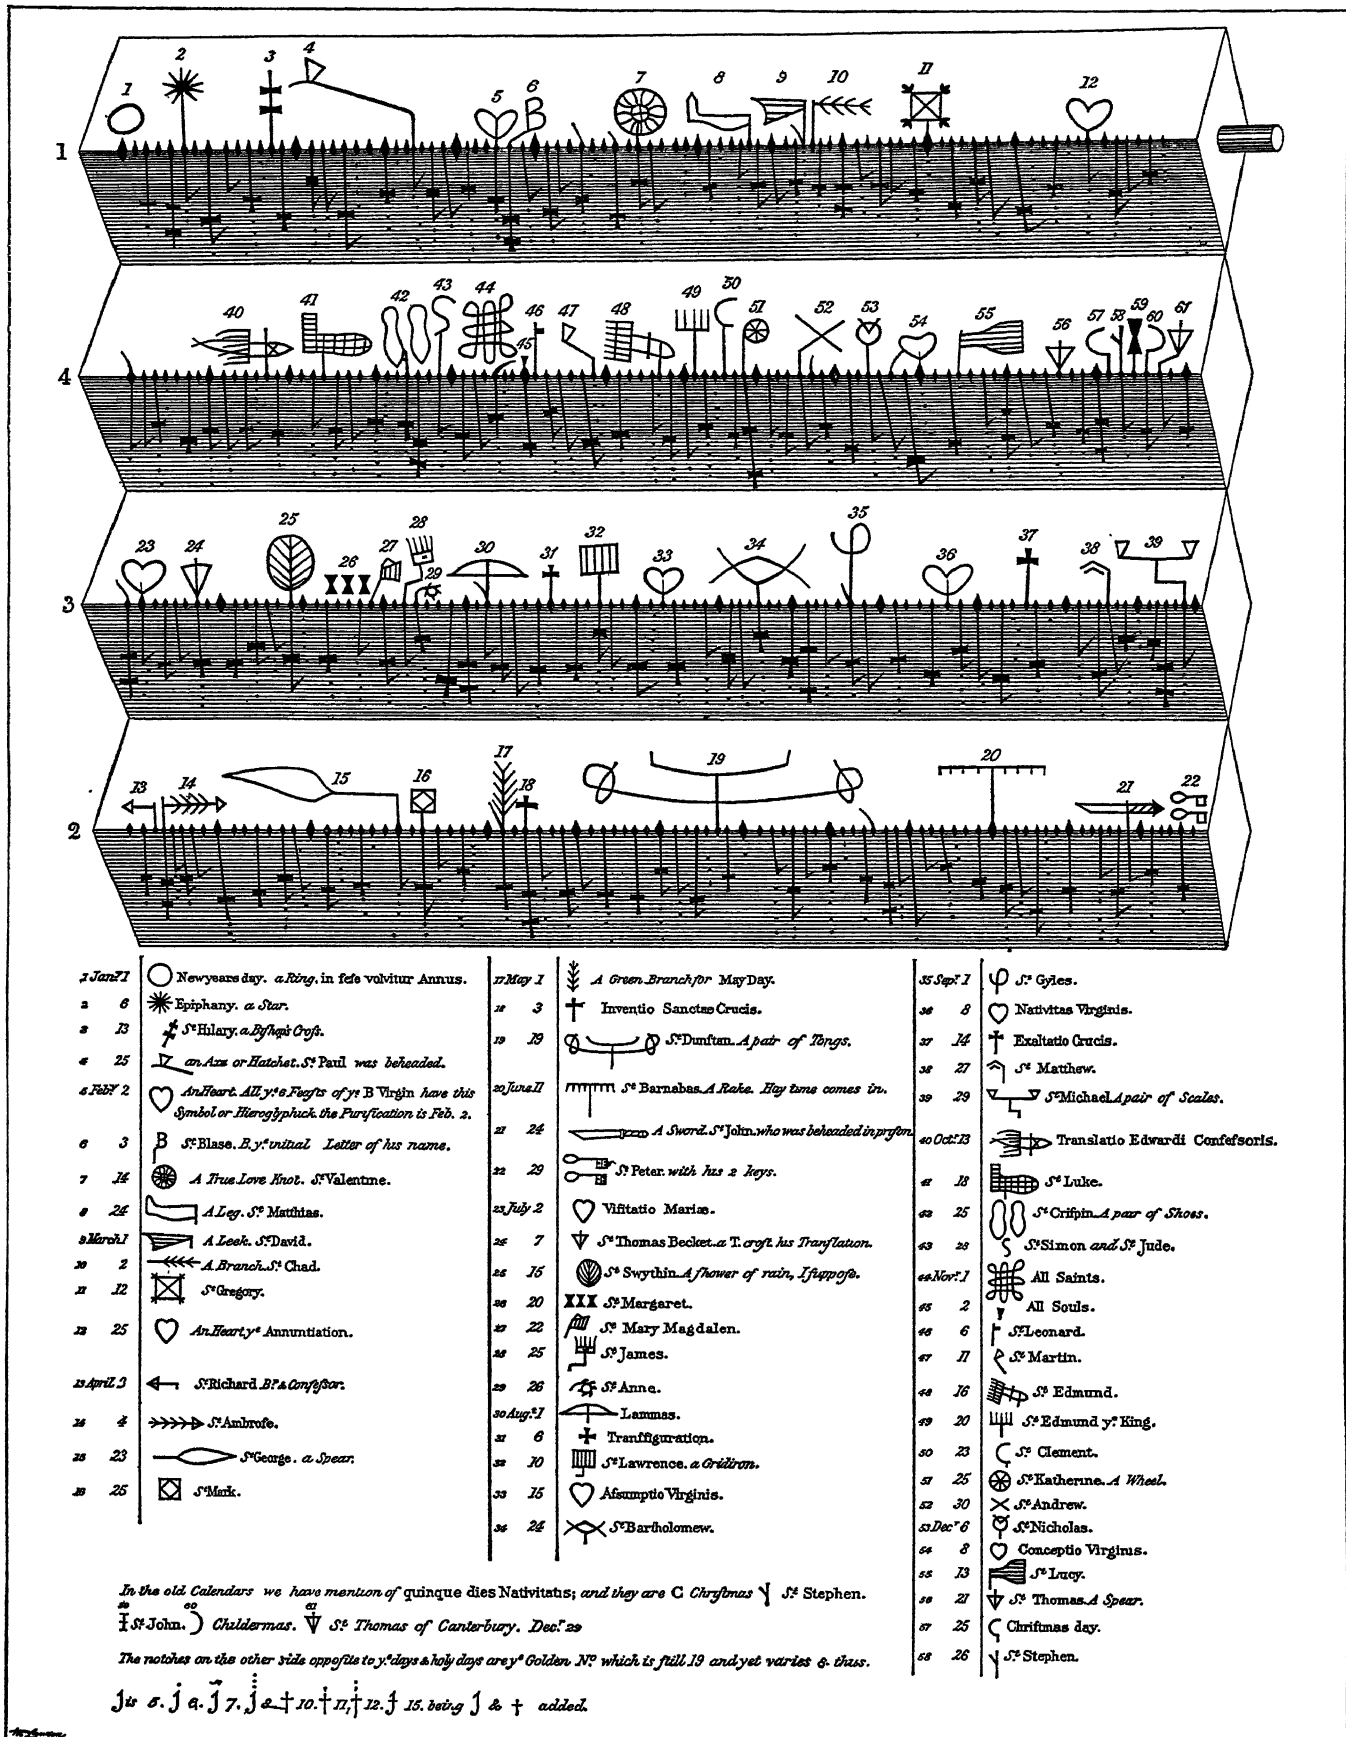

ALMA MATER, a name, signifying "bounteous mother," given by the Romans to certain goddesses, especially to Ceres and Cybele, and now applied to universities and schools regarded as the "foster mothers" of those who have attended them.

ALMANAC, a book or table containing a calendar of the days, weeks, and months of the year, a register of ecclesiastical festivals and saints' days, and a record of various astronomical phenomena, etc.

The attention given to astronomy by Eastern nations probably led to the early construction of such tables as are comprised in our almanacs; of these we know little or nothing. The *fasti* (*q.v.*) of the Romans are far better known and were similar to modern almanacs. Almanacs of a rude kind, known as *clogg almanacs*, consisting of square blocks of hard wood, about 8in. in length, with notches along the four angles corresponding to the days of the year, were in use in some parts of England as late as the end of the 17th century.

Early almanacs had commonly the name of "prognostications" in addition, and what they professed to show may be gathered from titles like the following, which is quoted by J. O. Halliwell: "Pronostycacyon of Mayster John Thybault, medycyner and astronomer of the Emperyall Majestie, of the year of our Lorde God MCCCCXXXIJ., comprehending the iiij. partes of this yere, and of the influence of the mone, of peas and warre, and of the sykenesses of this yere, with the constellacions of them that be under the vij. planettes, and the revolucions of kynges and princes, and of the eclipses and comets." Most English almanacs were published by the Stationers' Company, the most famous of them being the *Vox Stellarum* of Francis Moore (1657-1715?), the first number of which was completed in July 1700, and contained predictions for 1701. Its publication has been continued under the title of *Old Moore's Almanac*.

The exclusive right to sell "almanacs and prognostications" in England, enjoyed in the time of Elizabeth by two members of the Company of Stationers, was extended by James I. to the two universities and the Stationers' Company jointly; but the universities commuted their privilege for an annuity from the company. This monopoly was challenged by Thomas Carnan, a bookseller, who published an almanac for three successive years, after having been thrice imprisoned on that account by the company. The case came, in 1775, before the court of common pleas,

FROM "CAMDEN'S BRITANNIA" (GOUGH'S EDITION, 1806)

A CLOGG ALMANAC OF WOOD, THE ORIGINAL CALENDAR OF THE NORWEGIANS AND DANES

Each of the four edges contained the calendar for three months. The number of days in them were expressed by notches, and every seventh day by a large sized notch. Over against many of the notches were placed on the left hand, marks or symbols denoting the golden number of cycle of the moon. The festivals are marked with symbols of the several saints

and was decided in Carnan's favour. The company, however, virtually retained its monopoly for many years, but this power has altogether ceased, although a considerable proportion of the almanacs published in England still issue from the hall of the Stationers' Company.

On Jan. 1, 1828, the Society for the Diffusion of Useful Knowledge issued the *British Almanac* for that year. Its success, with its valuable supplement, the *Companion to the Almanac*, led to a great improvement in this class of publications. The Stationers' Company issued the *Englishman's Almanac*, a work of a similar kind. Since 1870, the *British Almanac* and *Companion* have been the principal almanacs published by the Stationers' Company. *Whitaker's Almanac*, commenced in 1868 by Joseph Whitaker (1820–1895), is perhaps the best known of modern almanacs.

In Scotland, almanacs containing much astrological matter appeared to have been published at about the beginning of the 16th century; and about a century later those published at Aberdeen enjoyed considerable reputation. In 1683, *Edinburgh's True Almanach*, or a *New Prognostication*, appeared, a publication which improved with years and was issued after 1837 as *Oliver and Boyd's New Edinburgh Almanac*, a standard book of reference for Scottish affairs. *Thom's Irish Almanac* (since 1843) deals mainly with Ireland.

The earliest almanac published in the United States is probably to be ascribed to Bradford's press in Philadelphia for the year 1687. *Poor Richard's Almanac*, commenced in 1732 by Benjamin Franklin under the pseudonym of "Richard Saunders," and continued by him for 25 years, gained a high reputation for its wise and witty sayings. *The American Almanac and Repository of Useful Knowledge* was published at Boston from 1828 to 1861. *The Old Farmer's Almanac* enjoys considerable popularity and has been published for many years.

In France prophetic almanacs circulated very freely among the poorer and rural classes, although an *Ordonnance* of Charles IX. required the seal of a diocesan bishop on all almanacs. In 1579 Henry III. prohibited the publication of predictions relating to political events, a prohibition renewed by Louis XIII. Of such almanacs, the most famous was the *Almanach Liégeois*, first published in 1625 at Liège by Matthieu Laensbergh. The most important French almanac is the *Almanach Royal*, afterwards *Impérial*, and now *National*, first published in 1679.

A number of publications, issued in Germany, from the middle of the 18th to the middle of the 19th century, under such titles as *Musenalmanach*, modelled on the *Almanach des Muses*, a contemporary almanac published at Paris, contain some of the best works of some of the most celebrated German poets. The *Almanach de Gotha*, which has existed since 1763, published since 1871 both in French and German, gives a particular account of all the royal and princely families of Europe, and ample details concerning the administration and the statistics of the different states of the world.

For the *Nautical Almanac* and similar publications see EPHEMERIS.

ALMANSA (ALMANZA), a town in Spain, province of Albacete, at the foot of a castle-topped crag, above a fertile plain, which is the principal "gate" to the interior of Spain on the Mediterranean side. Pop. (1920) 12,589. Almansa is, in consequence, an important railway junction, and was the scene of a decisive defeat of the British and their peninsular allies by the French under the Duke of Berwick (1707). (See SPANISH SUCCESSION, WAR OF THE.)

AL-MANŞŪR (Arab. "victorious"), a surname (laqab) assumed by a large number of Mohammedan princes. The best known are: (1) ABŪ JA'FAR IBN MOHAMMED, second caliph of the Abbasid house born A.D. 712, who reigned A.D. 754–775 and founded Baghdad in 764 (see CALIPHATE; § C, § 2); (2) ABŪ TĀHIR ISMA'IL IBN AL-QĀ'M, the third Fatimite caliph of Africa (946–953) (see FATIMITES); (3) ABŪ YŪSUF YA 'QUB IBN YUSUF, often described as Jacob Almanzor, of the Moorish dynasty of the Almohades, conqueror of Alfonso VIII. in the battle of Alarcos (1195); (4) IBN ABĪ 'AMR MOHAMMED, commonly called Almanzor by European writers, of an ancient but not illustrious Arab family, which had its seat at Torrox near Algeciras. The last-

named was born A.D. 939, and began life as a lawyer at Cordova. In 967 he obtained a place at the court of Hakam II., the Andalusian caliph, and rapidly rose to distinction, enjoying the powerful support of Subh, the favourite of the caliph, and mother of his heir Hishām. In 978, two years after the death of Hakam he became chief minister, but at first Manşūr had to share the power with his father-in-law Ghālib, the best general of Andalusia, and with Subh. At last a rupture took place between the two ministers. Ghālib professed himself the champion of the caliph and called in the aid of the Christians of Leon, but Manşūr, anticipating the struggle, had long before remodelled the army and secured its support. Ghālib fell in battle (981); a victorious campaign chastised the Leonese, and on his return to Cordova the victor became practically sovereign of Andalusia. The caliph was a mere prisoner of state, and Manşūr ultimately assumed the title of king (996). He reconquered territory from Christians, and restored the Muslim power in Spain. In Africa his armies were for a time hard pressed by the revolt of Zīrī, viceroy of Mauretania, but before his death this enemy had also fallen. Manşūr died at Medinaceli on Aug. 10, 1002, and was succeeded by his son Mozaffar.

ALMANZOR: see AL-MANŞŪR.

ALMA-TADEMA, SIR LAURENCE, or LAURENS (1836–1912), British artist, was born Jan. 8 1836, at Dronrijp, a Frisian village near Leeuwarden, the son of Pieter Tadema, a notary, who died when the boy was four years old. In 1852 he entered the Antwerp academy under Gustav Wappers, and subsequently that of Henri (afterwards Baron) Leys, whom he assisted in 1859 in painting the frescoes in the hall of the Hôtel de Ville at Antwerp.

In the exhibition of Alma-Tadema's collected works at the Grosvenor Gallery in London in the winter of 1882–83 were two pictures which may be said to mark the beginning and end of his first period. These were a portrait of himself, dated 1852, and "A Bargain," painted in 1860. His first great success was a picture of "The Education of the Children of Clovis" (1861), which was exhibited at Antwerp. In the following year he received his first gold medal at Amsterdam.

In the '60s and '70s he produced two series of pictures, the subjects of which are drawn from Merovingian and Egyptian history. These had a considerable popular vogue because each of them told a "story." But Alma-Tadema's most characteristic work was done in his scenes from Greek and Roman life. Among the best known of his earlier pictures of scenes from classical times are "Tarquinius Superbus" (1867), "Phidias and the Elgin Marbles" (1868), and "The Pyrrhic Dance" and "The Wine Shop" (1869). "The Pyrrhic Dance," though one of the simplest of his compositions, is one of the best. "The Wine Shop" is one of his many pictures of historical *genre*, but marked with a humour more robust than usual.

In 1863 Alma-Tadema married a French lady, and lived at Brussels till 1869, when she died, leaving him two daughters, Laurence and Anna, both of whom afterwards made reputations—Laurence in literature, Anna in art. In 1869 he sent from Brussels to the Royal Academy two pictures, "Un Amateur romain" and "Une Danse pyrrhique," which were followed by three pictures, including "Un Jongleur," in 1870, when he came to London. In 1871 he married Miss Laura Epps, who also won a high reputation as an artist.

After his return to England he continued to exhibit important pictures each year, generally on subjects drawn from the classics. Apart from these large canvases he painted some small pictures of exquisite finish, like the "Gold-fish" of 1900. These, as well as all his works, are remarkable for the way in which flowers, textures and hard reflecting substances, like metals, pottery, and especially marble, are painted. His work shows much of the fine execution and brilliant colour of the old Dutch masters.

Alma-Tadema became a naturalized British subject in 1873, and was knighted on the occasion of Queen Victoria's 80th birthday, 1899. He was made an associate of the Royal Academy in 1876 and a Royal Academician in 1879. In addition he received honours in many of the capitals of Europe. He died on June 25 1912; a posthumous exhibition of his work was held in London in 1913.

See Georg Ebers, "Lorenz Alma-Tadema," *Westermann's Monatshefte*, Nov. and Dec. 1885, since republished in volume form; Helen Zimmern, "L. Alma-Tadema, his Life and Work," *Art Annual*, 1886; C. Monkhouse, *British Contemporary Artists* (London, 1899).

ALME or **ALMAI** (from *ālim*, "wise," "learned"), the name of a class of singing girls in Egypt who are present at festivals and entertainments and act as hired mourners at funerals. They are to be distinguished from the *ghawazee*, or dancing girls, who perform in the public streets, and are of a lower order.

ALMEIDA, DOM FRANCISCO DE (c. 1450–1510), the first viceroy of Portuguese India, was born in Lisbon about the middle of the 15th century. In March 1505, having received from Emmanuel I. the appointment of viceroy of the newly conquered territory in India, he set sail from Lisbon in command of a large and powerful fleet, and arrived in July at Quiloa (Kilwa), which yielded to him almost without a struggle. Mombasa was taken and destroyed, and its large treasures went to strengthen the resources of Almeida. At the island of Angediva, near Goa, and Cannanore, he built forts, and adopted measures to secure the Portuguese supremacy. Upon his arrival in India, he took up his residence in Cochin, where a Portuguese fort had been built by Alphonso d'Albuquerque in 1503.

The most important events of Almeida's brief but vigorous administration were the conclusion of a commercial treaty with Malacca, and the discoveries made by his son Lorenzo, who acted as his lieutenant. Lorenzo was probably the first Portuguese who visited Ceylon, where he established a settlement, and Fernando Soarez, a captain commanding a squadron of his fleet, appears to have been the first European to sight Madagascar. In 1508 he was killed at Dabul in a naval engagement with the Egyptians, who at this time endeavoured to dispute Portuguese supremacy in the Indian Ocean. His father was preparing to avenge his death when Albuquerque (q.v.) arrived in Cochin, and presented a commission empowering him to supersede Almeida in the government. He refused to recognize Albuquerque's commission, and cast him into prison.

The punishment he inflicted on the Arabs and their Egyptian allies was speedy and terrible. Sailing along the coast, he pillaged and burned various ports, including Goa and Dabul, and finally, encountering the enemy's combined fleet off Diu in Feb. 1509, he completely destroyed it. Returning immediately to Cochin, he held out for a few months against the claims of Albuquerque, but in Nov. 1509 he was compelled to yield.

On Dec. 1 he set sail for Europe with an escort of three vessels. On the voyage the fleet called at Table bay, then known as Saldanha bay, to procure water, and here Almeida was killed (March 1, 1510) in an attack upon the Hottentot natives, during which he showed great personal courage. In this fight, which took place on the site of Cape Town, 65 Portuguese perished, including 12 captains. Almeida's body was recovered on the following day and buried on the spot where he fell.

See Franz Hümmerich, *Die erste deutsche Handelsfahrt nach Indien, 1505–06*, Historische Bibliothek, Bd. 49 (1922).

ALMEIDA, a town of north-eastern Portugal, in the district of Guarda; situated in hilly country near the River Cõa, a tributary of the Douro, and long an important frontier fortress. Pop. (1920) 1,599. During the Peninsular War (q.v.) much fighting occurred between the Cõa and the Spanish fortress of Ciudad Rodrigo, 25m E.S.E. Almeida was taken by the French in 1810, and its recapture, by allied British and Portuguese forces, was only effected after a relieving force under Marshal Masséna had been defeated at Fuentes de Oñoro, 13m. S.S.E., on May 5, 1811.

ALMELO, town in the province of Overysel, Holland, 12m. by rail N.W. of Hengelo, at the junction of the Overysel and Almelo canals. Pop. (1927) 28,743. The lordship of Almelo belonged to the lords of Heeckeren, who acquired the barony of Rechteren by marriage in 1350, and the countship of Limpourg in 1711. A branch of the family still holds the seat. The town has shared in the extraordinary development of the Twente district and possesses many cotton and other textile factories. This industrial development received a great impetus (1914–18) through the advantages of neutrality enjoyed by Holland.

ALMENDRALEJO, a town in Spain, province of Badajoz, 27 m. E.S.E. of Badajoz. Pop. (1920) 15,448. The town has an important annual sheep fair, handles much farm produce and makes brandy. Local Roman antiquities are preserved in a museum in the palace of the Marqués de Monsalad. The development of the Merida-Seville Railway (1875–1905) increased the trade in grain, fruit and wine of the Guadiana valley and the Tierra de Barros highland.

ALMERÍA, maritime province in southern Spain, formed in 1833, from the parts of the ancient kingdom of Granada. Pop. (1920) 358,149; area, 3,391sq.m. This most easterly part of Upper Andalusia (see ANDALUSIA), is crossed by sierras in which terminate successive zones of the Andalusian, or Baetic, Cordillera. The Sierra de Gádos and Sierra Alhamilla form part of, or continue, the Alpujarra system (see ALPUJARRAS); the Sierra de los Filabres continues the Nevada core of the Cordillera, while the enveloping crystalline of the Málaga zone is represented in the Sierra de las Estancias. The intervening valleys of the rivers Adra, Andaraz-Almería, and Almanzora provide the only fertile land. The annual rainfall is below 200mm. in the east of the province, and the supply of water for irrigation is most irregular. For these reasons Almería has always been notable for the number of absentees, who may be described as temporary drought-refugees. Despite the high birth-rate, the population (105.6 per sq.m.) has actually fallen since 1900. Minerals and grapes, with oranges and esparto to a lesser extent, are the only significant exports. Only 40% of the area is cultivated; there are no large systems of irrigation; but some fruit-growing districts produce well, especially white Almería grapes of which 2,000,000 barrels are exported annually. The demand for packing material has a considerable effect on the cork trade of Andalusia, Estremadura and Catalonia. The livestock of the province was tragically diminished by a series of dry years before 1920, but is now recovering, sheep (339,000 in 1924) taking the lead. Almería is rich in minerals, especially iron and lead; gold, silver, salt, barium sulphate, white lead, sulphur and zinc are also obtained. Fine marble is quarried in the Sierra Nevada. Roads are poor, but railways serve the mining areas. The principal seaports are Almería, the capital, pop. (1920) 50,194, Adra (8,565), and Garrucha (4,416), which, with Berja (10,224), Cuevas de Vera (20,403), Huércal-Overa (15,982) and Nijar (10,809), are described in separate articles. Education is backward, 66 % of the population being illiterate (1920), and the standard of comfort low. In the districts of Cuevas de Vera, Sorbas and Berja there are numerous groups of caves used as habitations.

ALMERÍA, capital of the province of that name, was the ancient Urci (or Portus Magnus), one of the chief harbours of Spain under the Romans after 19 B.C. Under the Muslims it was a great arsenal (al meriya—the watch-tower and harbour). After the fall of the Umayyads it became the head of a small independent state and then (1288–1489) a petty kingdom dependent on Granada. The dismantled Castillo de San Cristóbal with four Moorish towers overlooks the city which stands at the mouth of a rich alluvial valley enclosed by hills. It is an episcopal see with a Gothic cathedral (1524), and the terminus of a railway from Madrid. Pop. (1920) 50,194. The harbour, sheltered and adapted for vessels of large draught, is equipped with oil-fuel depôts and all modern facilities. About 1,400 ships (c.1,000,000 tons) per annum bring fuel and timber and take away iron, lead, esparto, and fruit, especially white grapes.

See D. F. Margall, *Almería* (Barcelona, 1886).

ALMERY: see AMBRY.

ALMODÓVAR DEL CAMPO or **ALMODOVAR**, a town of Spain, province of Ciudad Real, north of the Sierra de Alcudia. Pop. (1920) 12,635. Almodóvar was a Muslim fortress in the middle ages (Ar. *al-mudawwar*, round). It owes its modern prosperity to the valuable Puertollano coal-field, 3 m. to the south by a branch of the Madrid-Badajoz-Lisbon railway. At Horcajo (1½ m.) and elsewhere in the vicinity are mines of argentiferous lead. South of the Sierra lies the Alcudia valley, crown-owned pasture for immense sheep flocks.

ALMOGÁVARES (from the Arab. *Al-Mugavari*, a scout), the name of a class of Spanish soldiers who came originally from the Pyrenees, and were in later times recruited mainly in Navarre, Aragón and Catalonia. They were frontiersmen and professional foot-soldiers who wore no armour, dressed in skins, were shod with brogues (*abarcas*), and carried the same arms as the Roman legionaries—two heavy javelins (Spanish *azagaya*, the Roman pilum), a short stabbing sword and a shield. When Peter III. of Aragón made war on Charles of Anjou after the Sicilian Vespers—March 30, 1282—for the possession of Naples and Sicily, the Almogávares formed the most effective element of his army. When the Peace of Calatavut in 1302 ended the war in southern Italy, the Almogávares followed Roger di Flor (Roger Blum) the unfrocked Templar, who entered the service of the emperor of the East, Andronicus, as *condottieri* to fight against the Turks. When Roger di Flor was assassinated by his Greek employer in 1305, they turned on the emperor, held Gallipoli and ravaged the neighbourhood of Constantinople. In 1310 they marched against the duke of Athens, of the French house of Brienne. Walter of Brienne was defeated and slain by them with all his knights at the battle of Cephissus, or Orchomenus, in Boeotia in March. The foundation of the Aragonese duchy of Athens was the culmination of the achievements of the Almogávares. In the 16th century the name died out. It was, however, revived for a short time as a party nickname in the civil wars of the reign of Ferdinand VII.

See Ramon de Muntaner's *Chronicle* (Eng. trans. Lady Goodenough, 1920); G. Schlumberger, *Expédition des "Almogávares" ou routiers catalans en orient, de l'an 1302 à l'an 1311* (1902).

ALMOHADES (properly *Muwāḥḥadis*, i.e., "Unitarians"), a Mohammedan religious power which founded the fifth Moorish dynasty in the 12th century, and conquered all northern Africa as far as Egypt, together with Muslim Spain. It originated with Mohammed ibn Tūmart, a member of the Mašmūda, a Berber tribe of the Atlas. Ibn Tūmart was the son of a lamplighter in a mosque and had been noted for his piety from his youth; he was small, ugly and misshapen and lived the life of a devotee-beggar. He represented a revolt against the anthropomorphism of commonplace Mohammedan orthodoxy, but he was a rigid predestinarian and a strict observer of the law. After his return from Mecca and Baghdad to Morocco at the age of 28, he began preaching and agitating, heading riotous attacks on wine-shops and on other manifestations of laxity. He even went so far as to assault the sister of the Murābīṭi (Almoravide) amir 'Alī III., in the streets of Fez, because she was going about unveiled after the manner of Berber women. 'Alī, who was very deferential to any exhibition of piety, allowed him to escape unpunished.

Ibn Tūmart, who had been driven from several other towns for exhibitions of reforming zeal, now took refuge among his own people, the Mašmūda, in the Atlas. It is highly probable that his influence would not have outlived him, if he had not found a lieutenant in 'Abd-el-Mūmin el Kūmi, another Berber, from Algeria, who was undoubtedly a soldier and statesman of a high order. When Ibn Tūmart died in 1128, 'Abd-el-Mūmin not only rooted out the Murābīṭis, but extended his power over all northern Africa as far as Egypt, becoming amir of Morocco in 1149. He died in 1163, and in 1170 the Muwāḥḥadis transferred their capital to Seville, a step followed by the founding of the great mosque, now superseded by the cathedral, the tower of which they erected in 1184 to mark the accession of Ya'kūb el Maṣṣūr. From the time of Yūsef II., however, their amirs crossed the straits only to lead a *jihad* against the Christians and to return to their capital, Marrākesch.

The Muwāḥḥadi princes had a longer and a more distinguished career than the Murābīṭis or "Almoravides" (*q.v.*). Yūsef II. or "Abu Ya'kūb" (1163–84), and Ya'kūb I. or "El Maṣṣūr" (1184–99), the successors of 'Abd-el-Mūmin, were both able men. They were fanatical, and their tyranny drove numbers of their Jewish and Christian subjects to take refuge in the growing Christian States of Portugal, Castile and Aragón. But in the end they became less fanatical than the Murābīṭis, and Ya'kūb el Maṣṣūr was a highly accomplished man, who wrote a good Arabic style and protected the philosopher Averroes. His title of El Maṣṣūr, "The

Victorious," was earned by the defeat he inflicted on Alphonso VIII. of Castile at Alarcos in 1195. In 1212 Mohammed III., "En-Nāṣir" (1199–1214), the successor of El Maṣṣūr, was utterly defeated by the allied five Christian princes of Spain, Navarre and Portugal, at Las Navas de Tolosa in the Sierra Morena.

The amirs of the Muwāḥḥadi Dynasty were as follows: 'Abd-el-Mūmin (1145); Yūsef II., "Abu Ya'kūb" (1163); Ya'kūb I., "Abu Yūsef el Maṣṣūr" (1184); Mohammed III., "En-Nāṣir" (1199); Yūsef III., "Abu Ya'kūb el Mustanṣir" (1214); 'Abd-el-Wāhid, "El Makhlūwī" (1223); 'Abd-Allah II., "Abu Mohammed" (1224); Yahya V., "El Mu'taṣim" (1226); Idris III., "El Māmūn" (1229); Rashid I., "Abd-el-Wāhid II." (1232); 'Alī IV., "Es-Sa'id el Mu tadid" (1242); Omar I., "El Mortaḍa" (1248); Idris IV., "El Wāthik" (1266–69). (B. M.; D. H.)

ALMON, JOHN (1737–1805), English political pamphleteer and publisher, was born at Liverpool on Dec. 17, 1737, and died on Dec. 12, 1805. He came to London in 1758 at a time when the Whig opposition, hampered and harassed by the Government to an extent that threatened the total suppression of independent opinion, needed a channel of publicity, which they found in Almon. He was already known by *The Conduct of a late Noble Commander* (Lord George Sackville); *Examined* (1759); a *Review of his late Majesty's Reign* (1760); *A Review of Mr. Pitt's Administration* (1761); and a number of letters on political subjects. The review of Pitt's administration secured for Almon the friendship of Earl Temple, to whom it was dedicated. In 1763 he opened a bookseller's shop in Piccadilly, chiefly for the publication and sale of political pamphlets. In 1765 the attorney-general moved to have him tried for the publication of the pamphlet entitled *Juries and Libels*, but the prosecution failed; and in 1770, for merely selling a copy of the *London Museum* containing Junius's celebrated "Letter to the King," he was sentenced by Lord Mansfield to pay a fine of ten marks and give security for his good behaviour. It was this trial that called forth the letter to Lord Mansfield, one of the bitterest of the Junius series. In 1774 Almon commenced the publication of his *Parliamentary Register*, a monthly report of the debates in Parliament, and he also issued an abstract of the debates from 1742, when Richard Chandler's *Reports* ceased, to 1774. He became proprietor in 1784 of the *General Advertiser*, in the management of which he lost his fortune and was declared insolvent. To these calamities was added an imprisonment for libel. Almon had to leave the country, but after some years in France he returned and resumed business, publishing among other works an edition of Junius. His last publication was an edition of Wilkes's correspondence, with a memoir (1805).

ALMOND, the fruit of the almond tree (*Prunus Amygdalus*), which belongs to the plum tribe (*Prunee*) of the rose family (*Rosaceae*). It used to be placed in a separate genus *Amygdalus*, the distinction lying in the fruit, the soft pulp attached to the stone in the plum being replaced by a leathery separable coat in the almond. The tree appears to be a native of western Asia, Barbary and Morocco; but it has been extensively distributed over the warm-temperate region of the Old World. It ripens its fruit in the south of England. It is a tree of moderate size; the leaves are lanceolate, and serrated at the edges; and it flowers early in spring. The fruit is a drupe, having a downy outer coat, called the epicarp, which encloses the reticulated hard stony shell or endocarp. The seed is the kernel which is contained within these coverings. The shell-almonds of trade consist of the endocarps enclosing the seeds. The tree grows in Syria and Palestine; and is referred to in the Bible under the name of *Shaked*, meaning "hasten." The word Luz, which occurs in Genesis xxx. 37, and which has been translated hazel, is supposed to be another name for the almond. In Palestine the tree flowers in January, and this hastening of the period of flowering seems to be alluded to in Jeremiah i. 11, 12, where the Lord asks the prophet, "What seest thou?" and he replies, "The rod of an almond-tree"; and the Lord says, "Thou hast well seen, for I will hasten my word to perform it." The application of *Shaked* or hasten to the almond is like the use of "May" for the hawthorn, which usually flowers in that month in Britain. The rod of Aaron, mentioned in Numbers xvii, was taken

from an almond-tree; and the Jews still carry rods of almond-blossom to the synagogues on great festival days. The fruit of the almond supplied a model for certain kinds of ornamental carved work (Exodus xxv. 33, 34; xxxvii. 19, 20).

There are two forms of the plant, the one (with pink flowers) producing sweet, the other (with white flowers) bitter almonds. The kernel of the former contains a fixed oil and emulsin. It is used internally in medicine, and must not be adulterated with the bitter almond.

The bitter almond is rather broader and shorter than the sweet almond and has a bitter taste. It contains about 50% of the fixed oil which also occurs in sweet almonds. It also contains a ferment *emulsin* which, in the presence of water, acts on a soluble glucoside, *amygdalin*, yielding glucose, prussic acid and the essential oil of bitter almonds or benzaldehyde (*q.v.*), which is not used in medicine. Bitter almonds may yield from 6 to 8% of prussic acid.

Cultivation of sweet almonds has been established in climatically suitable districts in the United States, chiefly on the Pacific coast. According to the census of 1920, the total commercial crop exceeded 15,850,000 lb., of which 99% was produced in California.

Recipes.—Below are given certain commonly needed almond recipes:—

Almond Cake.—A standard recipe for this is: Beat 6 oz. of warmed castor sugar into four eggs until the mixture is the thickness of cream. Add 3 oz. melted butter, mix in $\frac{1}{2}$ oz. pounded almonds (bitter), 1 lb. sifted flour, and essence of lemon to taste. Place the mixture in a greased mould and bake $1\frac{1}{2}$ –2 hours in a steady oven. Beware of burning.

Almond Paste.—A standard recipe for this is: Bring to the boil 6 oz. of loaf sugar with a teaspoonful of lemon juice; skim and boil to 237° F. Pour the syrup on to 4 oz. ground almonds, mix in the white of half an egg and use as required. The traditional cook's method of ascertaining when the sugar has reached the proper temperature is called small balls, because the sugar, when a portion is removed by the forefinger into cold water, can be rolled into a small ball.

Almonds, Salted.—To salt blanched almonds, fry them till brown in olive oil, drain and roll or toss them in a mixture of celery salt ($\frac{3}{8}$ ths) and cayenne pepper ($\frac{1}{8}$ th).

ALMOND OIL, the fixed oil termed in the British Pharmacopoeia *Oleum amygdalae*, is obtained from the ground blanched kernels of the fruit of the almond, either by expression or by extraction with a volatile solvent; the latter process is used in the case of damaged seeds where the residual meal is valueless. The commercial oil is prepared from the kernels of the bitter almond (*Prunus amygdalus*, var. *amara*), or from a mixture of these and the seeds of the sweet variety. Yield from sweet almonds ranges from 44%–55%; the bitter variety averages 35%–45% of oil.

The expressed oil is pale yellow in colour and possesses a bland, nutty flavour; the extracted oil is darker and has a harsh taste. Almond oil is used in pharmacy as a vehicle for drugs, and is employed in the preparation of cosmetics. Its scarcity leads to extensive sophistication, the usual adulterants being apricot, plum and peach kernel oils, which closely resemble almond oil.

Oleum amygdalae amaræ (essentiale), "ethereal bitter almond oil," is produced by trituration of the oil-free meal of bitter almonds with water. The natural ferment *emulsin* acting on the glucoside *amygdalin* also present in the seed produces a mixture of glucose, benzaldehyde and prussic acid. The distilled product contains up to 5% prussic acid, which is removed by treatment with lime and iron sulphate when the essence is required for flavouring purposes.

BIBLIOGRAPHY.—See Lewkowitsch, *Oils, Fats, and Waxes* (1921); *British Pharmacopoeia*; *U.S. Pharmacopoeia*. (E. L.; G. H. W.)

ALMONER, an officer charged with the distribution of alms, primarily for a religious house or bishop (from Lat. *eleemosynarius*, through M. Lat. *almonarius* and Fr. *almosnier*). Almoners attached to the French court appear early, but the title of grand almoner of France first appears in 1486. The office, which acquired great importance through its control of preferments, was revived by Napoleon I. and again by Napoleon III., but was

abolished in 1870. In England the offices of hereditary grand almoner (a sinecure held by the marquess of Exeter), and lord high almoner still exist. The latter, usually a bishop or other prelate, distributes the royal alms of silver pennies on Maundy Thursday (*q.v.*).

ALMONRY, the name for the place where alms were distributed to the poor in churches or other ecclesiastical buildings. At Bishopstone church (Wilts.), it is a sort of covered porch attached to the south transept, but not communicating with the interior of the church. At Worcester cathedral the alms are said to have been distributed on stone tables, on each side, within the great porch. In large monastic establishments, as at Westminster, it seems to have been a separate building of some importance, either joining the gatehouse or near it.

ALMORA, a town and district of British India, the chief town and administrative headquarters of the Kumaon division of the United Provinces, situated on a mountain ridge of the Himalayas 5,494 ft. above the sea. Pop. (1921), 8,359. The town has a college called after Sir Henry Ramsay, several schools and a large cantonment. The climate is supposed to be particularly kindly to sufferers from lung trouble. The town was captured in 1790 by the Gurkhas, who constructed a fort on the eastern extremity of the ridge. Another citadel, Ft. Moira, is situated at the other end of the ridge. Almora is also celebrated as the scene of the British victory which terminated the war with Nepal in 1815.

The district of Almora was constituted in 1891, together with Naini Tal, by a redistribution of the two former districts of Kumaon and the Tarai. It lies among the mountains of Kumaon between the upper waters of the Ganges and the Gogra, here called the Kali. Area, 5,389 sq. m.; pop. (1921), 530,338. Tea is grown in the district, which includes the military sanatorium of Ranikhet.

ALMORAVIDES (properly *Murābtis*, i.e., "religious ascetics"), a Berber horde from the Sahara which, in the 11th century, founded the fourth dynasty in Morocco. The most powerful of the invading tribes was the Lamtūna ("veiled men") from the upper Niger, whose best-known representatives now are the Tuareg.

They had been converted to Mohammedanism in the early times of the Arab conquest, but their knowledge of Islam did not go much beyond the formula of the creed—"there is no god but God, and Mohammed is the apostle of God,"—and they were ignorant of the law. Their first military leader, Yahya ibn Omar, gave them a good military organization. Their main force was infantry, armed with javelins in the front ranks and pikes behind, formed into a phalanx and supported by camelmen and horsemen on the flanks. From the year 1053 the Murābtis began to impose their orthodox and puritanical religion on the Berber tribes of the desert, and on the pagan negroes. Yahya was killed in battle in 1056, but Abd-Allah, whose influence as a religious teacher was paramount, named his brother Abu Bakr as chief. In 1061 Abu Bakr made a division of the power he had established, handing over the more settled parts to his cousin Yūsef ibn Tashfīn, as viceroy, resigning to him also his favourite wife Zāināb, who had the reputation of a sorceress.

Ibn Tashfīn, who was largely guided by Zāināb, had in the meantime brought what is now known as Morocco to complete subjection, and in 1062 had founded the city of Marrākesh ("Morocco City"). He is distinguished as Yūsef I. In 1080 he conquered the kingdom of Tlemçen and founded the present city of that name, his rule extending as far east as Oran. In 1086 he was invited by the Mohammedan princes in Spain to defend them against Alphonso VI., king of Castile and Leon. In that year Yūsef passed the straits of Algeciras, and on Oct. 23 inflicted a severe defeat on the Christians at Sacralias, or in Arabic, Zallāka, near Badajoz. He was debarred from following up his victory by trouble in Africa which he had to settle in person. When he returned to Spain in 1090 it was avowedly for the purpose of deposing the Mohammedan princes and annexing their states. By 1094 he had removed them all, and though he regained little from the Christians except Valencia, he reunited the Mohammedan power and gave a check to the reconquest of the country by the

Christians. After friendly correspondence with the caliph at Baghdad, whom he acknowledged as Amīr el Mūminīn, "Prince of the Faithful," Yūsef in 1097 assumed the title of "Prince of the Resigned"—Amīr el Muslimīn. He died in 1106, when he was reputed to have reached the age of 100.

The Murābīti power was at its height at Yūsef's death, and the Moorish empire then included all north-west Africa as far as Algiers, and all Spain south of the Tagus, with the east coast as far as the mouth of the Ebro, and the Balearic islands. Three years afterwards, under Yūsef's son and successor, 'Alī III. of Morocco, Madrid, Lisbon and Oporto were added, and Spain was again invaded in 1119 and 1121, but the tide had turned, and the conquest of the city of Marrākesh by the Muwāhḥadis in 1147 marked the fall of the dynasty, though fragments of the Murābītis continued to struggle in the Balearic islands, and finally in Tunisia.

The amirs of the Murābīti dynasty were as follows:—Yūsef I., bin Tashfīn (1061); 'Alī III. (1106); Tashfīn I. (1143); Ibrāhim II. (1145); Ishāk (1146).

See the anonymous *Raōd el Karṭās* (Fez, 1326), translated by Baymīer as *Roudh el-Kartas* (Paris, 1860); Ibn Khaldūn, *Kitāb el 'Aībr . . . fi Aiyām el Maghrib*, etc. (c. 1405), partly translated by de Slane as *Histoire des Berbers*, vol. ii. (Algiers, 1852-56); Makkārī, *History of the Mahommedan Dynasties in Spain*, translated by Gayangos (London, 1840); R. Dozy, *Histoire des Musulmans d'Espagne*, vol. iv. (Leyden, 1861); B. Meakin, *The Moorish Empire* (1899). (B. M.; D. H.)

ALMQVIST, KARL JONAS LUDWIG (1793-1866), Swedish writer, was born at Stockholm in 1793. He became a student at Uppsala, where his father was professor of theology, in 1808, and took his degree in 1815. In 1823 he threw up the position he held in the capital to lead a colony of friends to the wilds of Wermland. The experiment was a failure, and in 1828 he returned to Stockholm as a teacher in the new elementary school there, of which he became rector in 1829.

The publication of his great series of novels, *The Book of the Thorn-Rose* (1832-35), made him famous, and few writers have equalled Almqvist in productiveness and versatility. Poems, romances, lectures and treatises on many subjects form the most prominent of his countless contributions to modern Swedish literature; and, so excellent was his style, that in this respect he has been considered the first of Swedish writers. His life was as varied as his work. Unstable in all his doings, he passed from one lucrative post to another, at last subsisting entirely on the proceeds of literary labour. More and more vehemently he espoused the cause of socialism in his brilliant novels and pamphlets; friends were beginning to leave him, when suddenly all minor criticism was silenced by the astounding news that Almqvist, convicted of forgery and charged with murder, had fled from Sweden (1851).

For many years no more was heard of him; but it is now known that he went over to America and settled in St. Louis. During a journey through Texas he was robbed of all his manuscripts, among which are believed to have been several unprinted novels. He is said to have appealed in person to President Lincoln, but the robbers could not be traced. In 1865 he returned to Europe, and his strange existence came to a close at Bremen on Sept. 26, 1866. It is by his romances that his literary fame will mainly be supported; but his singular history will always point him out as a remarkable figure, even when his works are no longer read. He was another Eugene Aram, but of greater genius, and so far more successful that he escaped the judicial penalty of his crime.

See his *Samlade Skrifter* (ed. F. Böök, Stockholm, 1920-23).

ALMS, the giving of relief, and the relief given, whether in goods or money, to the poor, particularly applied to the charity bestowed under a sense of religious obligation. Like "riches" the word is often wrongly treated as a plural. (See CHARITY.)

ALMSHOUSE, a building for the residence of poor or aged people. In England the term is generally used of those built and endowed by private charity and frequently better treatment is given to the inmates than in the publicly supported workhouses. In America the term is synonymous with "poorhouse" (workhouse). An interesting mediaeval example is the Hospital of St. Cross, near Winchester, founded 1136.

ALMUCE, a hooded cape of fur, or fur lined, worn as a choir vestment by certain dignitaries of the Western Church (late Lat. *almucia*, *almucium*, *armucia*, etc.). It was originally a head covering only, and the German word *Mütze*, "cap," is derived from it. The name of another vestment akin to the almuce—the *mozzetta*—has been by some traced to the word *nutzen*, to dock, cut off, through the Ital. *mozzare* and *mozzo* (but see below).

In numerous documents from the 12th to the 15th century the *almucium* is mentioned, occasionally as identical with the hood, but more often as a sort of cap distinct from it; e.g., in the decrees of the council of Sens (1485)—*non caputia, sed almucia vel bireta tenentes in capite*. In the late 13th century two types of *almucium* were distinguished: (1) a cap coming down just over the ears; (2) a hood-like cap falling over the back and shoulders. This latter was reserved for the more important canons, and was worn over surplice or rochet in choir. The introduction of the biretta (*q.v.*) in the 15th century tended to replace the use of the almuce as a head covering, and the hood now became smaller, while the cape was enlarged till, in some cases, it fell below the elbows. Almuces were occasionally made of silk or wool, but from the 13th century onward usually of fur, the hem being sometimes fringed with tails. Hence they were known in England as "grey amices" (from the ordinary colour of fur), to distinguish them from the liturgical amice (*q.v.*). By the 16th century the almuce had become definitely established as the distinctive choir vestment of canons; but it had ceased to have any practical use, and was often only carried over the left arm as a symbol of office. It has now been almost entirely superseded by the *mozzetta*, but is still worn in certain cathedrals. The "grey amice" of the canons of St. Paul's in London was put down in 1549, the academic hood being substituted.

See du Cange, *Glossarium*, s. "Almucia"; Joseph Braun, *Die liturgische Gewandung*, p. 355, etc. (Freiburg im Breisgau, 1907); also the bibliography to the article VESTMENTS.

ALNAGE or **AULNAGE**, the official supervision of the shape and quality of manufactured woollen cloth, the derivation being from Fr. *aune*, ell. It was first ordered in the reign of Richard I. that "woollen cloths, wherever they are made, shall be of the same width, to wit, of two ells within the lists, and of the same goodness in the middle and sides." This ordinance is usually known as the Assize of Measures or the Assize of Cloth. Article 35 of Magna Charta re-enacted the Assize of Cloth, and in the reign of Edward I. an official called an "alnager" was appointed to enforce it. His duty was to measure each piece of cloth, and to affix a stamp to show that it was of the necessary size and quality. As, however, the diversity of the wool and the importation of cloths of various sizes from abroad made it impossible to maintain any specific standard of width, the rules as to size were repealed in 1353.

The increased growth of the woollen trade and the introduction of new and lighter drapery in the reign of Queen Elizabeth compelled a revision of the old standards. A statute was passed in 1665 creating the office of alnager of the new drapery and defining the sizes to which cloth should be woven. The objects of the statute were to prevent people being deceived by buying spurious woollen cloth and to provide against fraud and imposition. Alnage duties and the office of alnager were abolished in 1699.

See W. J. Ashley, *Economic History*; and W. Cunningham, *Growth of English Industry and Commerce*.

ALNWICK, urban district and county-town of Northumberland, England, 309 m. N. by W. from London, on a branch of the L.N.E.R.; Pop. of urban district (1931) 6,882. It is beautifully situated on the small river Aln, in a hilly district near the sea. Dominating the town from above the south bank of the river stands the castle, held by the Percys since 1309, and long before this an important border stronghold. A gateway of c. 1350 and a fine Norman arch of the middle of the 12th century are among noteworthy ancient portions. The castle has been extensively renovated and has largely lost its historic character. The town evidently grew up round the castle, and tradition states that it received its borough charter from King John,

but it is first definitely mentioned as a borough in a charter given by William de Vespy in the reign of Henry II. According to an inquiry of 1291 a market and fair were held in Alnwick from time immemorial. Edward I., in addition, granted the bishop of Durham a market on Saturday, and a fair on March 17 and six following days. By charters of Henry VI. the burgesses received licence to enclose their town with a wall, to have a free port at Alnmouth, a market on Wednesday as well as Saturday, and two new fairs. Tanning and weaving were formerly the principal industries carried on in Alnwick, and in 1646 there were 22 tanneries there.

Remains of the town wall are visible, and one of the four gates, the Bondgate, stands, dating from the early part of the 15th century. The church of St. Michael has Norman remains, but is principally Perpendicular. Within the confines of the park are ruins of two abbeys. Alnwick Abbey was a Premonstratensian foundation of 1147; only a gateway tower stands. Three miles from the town are more extensive remains of Hulne Abbey (1240), an early Carmelite monastery. The long narrow church remains unroofed; there are also a gateway tower, and portions of the chapter-house and cloisters. The Norman chapel of the hospital of St. Leonard, and Alnwick Abbey, were founded by Eustace FitzJohn. Howick mansion, built in the 18th century, has a fine situation near the coast to the north-east. Not far away are the ruins of Dunstanborough Castle; it dates from the 14th century, though the site was probably occupied as a stronghold from earlier times.

The chief industries are brewing, tobacco, and fishing-tackle making. Alnwick is under an urban district council, but is a borough by prescription, and its freemen form a body corporate without authority over the affairs of the town.

ALOE, a genus of plants belonging to the family Liliaceae, with about 180 species growing in the dry parts of Africa, especially Cape Colony, and in the mountains of tropical Africa. Members of the closely allied genera *Gasteria* and *Haworthia*, with a similar mode of growth, are also cultivated and popularly known as aloes. The plants are apparently stemless, bearing a rosette of large, thick, fleshy leaves, or have a shorter or longer (sometimes branched) stem, along which, or towards the end, of which and its branches, the generally fleshy leaves are borne. They are much cultivated as ornamental plants, especially in public buildings and gardens, for their stiff, rugged habit. The leaves are generally lance-shaped with a sharp apex and a spiny margin; but vary in colour from grey to bright green, and are sometimes striped or mottled. The rather small tubular yellow or red flowers are borne on simple or branched leafless stems, and are generally densely clustered. The juice of the leaves of certain species yields aloes. In some cases, as in *Aloe venenosa*, the juice is poisonous. The American aloe, *Agave americana* (see AGAVE), belongs to a different family, viz., Amaryllidaceae.

Aloes is a medicinal substance used as a purgative and produced from various species of aloe, such as *A. vera*, *vulgaris*, *socotrina*, *chinensis*, and *Perryi*. Several kinds of aloes are distinguished in commerce—Barbadoes, Socotrine, hepatic, Indian, and Cape aloes. The first two are those commonly used for medicinal purposes. Aloes is the expressed juice of the leaves of the plant. When the leaves are cut the juice flows out, and is collected and evaporated. From the juice active principles termed *aloin*s are extracted by water.

The *lign-aloes* is quite different from the medicinal aloes. The word is used in the Bible (Numb. xxiv. 6), but as the trees usually supposed to be meant by this word are not native in Syria, it has been suggested that the LXX. reading in which the word does not occur is to be preferred. Lign-aloe is a corruption of the Lat. *lignum-aloe*, a wood, not a resin. Dioscorides refers to it as *agallochon*, a wood brought from Arabia or India, which was odoriferous but with an astringent and bitter taste. This may be *Aquilaria Agallocha*, a native of East India and China, which supplies the so-called eagle-wood or aloes-wood, which contains much resin and oil.

ALOIDAE (äl'ō-ī'dē), or **ALOADAE**; i.e., Otus and Ephialtes, in ancient Greek legend, the twin sons of Aloeus or

Poseidon, celebrated for their extraordinary stature and strength. According to Homer (*Od.*, xi. 305), they made war upon the Olympian gods and endeavoured to pile Pelion upon Ossa in order to storm heaven itself, but Apollo destroyed them before they reached manhood. In the *Iliad* (v. 365) Ares is imprisoned by them, but delivered by Hermes. They sought Artemis and Hera in marriage, whereupon Artemis appeared between them in the shape of a stag, which they endeavoured to kill, but slew each other. The Aloidae (Gr. *alōē*=threshing-floor) represent the spirits of the fertile earth and agriculture.

ALOMPRA, **ALOUNG P'HOURA** (1711–60), founder of the last Burmese dynasty, was chief of the village of Môtshobō; near Ava. Burma was at that time under the rule of Pegu. Alompra raised a small force of men, seized Ava in 1753, and gradually ousted the Peguans and made himself master of the country. For the wars which followed, in which Alompra invaded and subdued Pegu, see BURMA. He was undertaking the subjugation of Siam when he was taken ill, and died on May 15 1760. Alompra had undoubted military genius and a measure of political sagacity, and he sought to improve the administration of justice. His cruelty and deceitfulness were faults common to the oriental potentates of his time.

ÁLORA, a town of Málaga, southern Spain. Pop. (1920) 11,458. Álorá, an ancient and picturesque town (Rom. *Iluro*) stands at the foot of the *Hacho*, one of a series of table-lands along the line of the structural depression followed by the river Guadalhorce. The fertile *vega* irrigated from this river, and renowned for oranges, lemons and other fruits, is the uppermost part of the semi-circular *Hoya de Málaga*, which descends from the defile *El Chorro* to the coast near Málaga. There are hot sulphur springs in the town. Brandy distilling is, after agriculture, the chief local industry.

ALOST (Flem. *Aalst*), Belgium, province of East Flanders, on the left bank of the Dender; the ancient capital of "Imperial Flanders." Pop. (1925) 36,541. In the feudal period when Flanders was a fief of the king of France, there was a small strip extending from Alost to the isles of Zeeland, called Imperial Flanders, the count of which was the vassal of the Holy Roman emperor. The *hôtel de ville* has a fine 15th century belfry, damaged by fire in 1879. In the church of St. Martin, dating from 1498 but unfinished, is a fine Rubens, "St. Roch," said to have been painted in eight days. At Alost, Thierry Maartens (c. 1474) set up one of the first printing presses in Europe. The town is famous to-day for its hop gardens and linen-bleaching industry.

ALOYSIA: see VERBENA.

ALP, a term applied to the summer pastures of the Alps situated just below the snow-line, freed from snow each spring. Such mountain pastures are of great antiquity, being mentioned as early as the 8th century, and are found in all parts of the Alpine chain. In German Switzerland, particularly, the alps are the centre round which the pastoral life of the inhabitants turns. The *Alpgemeinden*, as the Swiss Alpine communes are called, are composed of the persons who have a right to send cattle up to the alps in summer, this right being attached either to certain plots of ground in the valley or certain houses in the village, or to certain persons. In any case the owners of an alp fix the greatest number of cows which it can support during the summer without being permanently damaged. A plot of ground which can support a single cow (or two heifers, three calves or sheep, four pigs or eight goats) is called a *Kuhstoss*. On each alp there are several sets of huts at different levels for the cow-herds and cheese-makers, the cattle being generally left in the open. These sets of huts, properly called *châlets* or *Sennhütten*—though the former term is also applied to houses in the village below—are used in turn between the end of June and the end of September. The cheese and butter are stored in huts and carried down to the village at the end of the season. Hay is never mown on the true alps save in spots which are not easily accessible to cattle, but it is made on the *Voralpen*, the lowest pastures, situated between the homesteads and the true alps; these *Voralpen* are individual (not communal) property and are grazed, to some extent, during the late spring and early autumn.

ALPACA, one of the two domesticated breeds of S. American camel-like hoofed mammals, derived from the wild guanaco (*q.v.*). Alpacas are kept in flocks on the level heights of the Andes in Chile, Peru and Bolivia, at an elevation of 14,000 to 16,000 ft. above the sea. In appearance the animal resembles a sheep, except for the long head and neck, carried erect. It is kept mainly for the sake of its wool, though the flesh is quite palatable. The alpaca is sheared yearly, the fleece consisting of thick woolly hair, about 8 in. of which is removed from the total length of 2 feet. In colour it is mainly black or dark brown, but lighter hues occur. The fibre is elastic, silky, lustrous and strong, and was used by the Peruvian Indians centuries before its introduction into Europe. It was due to the sagacity of Sir Titus Salt (*q.v.*) that the manufacture of alpaca cloth was successfully started in 1836. At the present day, however, most of the alpaca cloth of commerce is made from mohair and other types of fibre. (See also WOOL.) Scientifically, the alpaca is *Lama huanaco* var. *paca*. (See GUANACO; LLAMA; VICUÑA.)

BY COURTESY OF N.Y. ZOOLOGICAL SOCIETY
THE ALPACA. A DOMESTICATED ANIMAL BRED BY NATIVES OF THE ANDES FOR ITS VALUABLE WOOL

The four species of indigenous South American fibre bearing animals are the llama, the alpaca, the guanaco and the vicuña. These are all of the camel class, without humps but having the "water stomach." The llama, of which there are 700,000, and the alpaca, of which there are 1,500,000, are domesticated; the guanaco and the vicuña run wild. Of the four the alpaca and the vicuña are the most valuable fibre-bearing animals: the alpaca on account of the lustre and quantity, the vicuña on account of the softness, fineness and quality of its fibre. The usual length of alpaca staples appears to be about 12 in., this being a three years' growth; but the length may be little more than about half this, *i.e.*, a one to two years' growth, shearing being in part dependent upon the demand for and price of the fibre. The fleeces are sorted for colour and quality by skilled native women. The colour of the greater proportion of alpaca imported into the British Isles is black and brown, but there is also a fair proportion of white, grey and fawn. It is customary to mix these colours together, thus producing a curious ginger-coloured yarn, which upon being dyed black in the piece takes a fuller and deeper shade than can be obtained by piece-dyeing a solid white wool. In physical structure alpaca is akin to both hair and wool, having scales and some fibres medullated. It is probably a mixture of an outer and under fibre-coat. It is very glossy, and its softness and fineness enable the spinner to produce satisfactory yarns with comparative ease.

Alpaca Industry.—Alpaca is a name given to two distinct things. It is primarily a term applied to the fibre obtained from the alpaca. It is, however, more broadly applied to a style of fabric originally made from the alpaca fibre but now frequently made from allied types of fibres, *viz.*, mohair, Iceland or even from lustrous English wool. In the trade, distinctions are made between alpacas and the several styles of mohairs and lustres, but so far as the general purchaser is concerned little or no distinction is made.

The Romance of Alpaca.—The history of the manufacture of this fibre into cloth is one of the romances of commerce. Undoubtedly the Indians of Peru employed it in the manufacture of many styles of fabrics for centuries before its introduction into Europe as a commercial product. The first European importations would naturally be into Spain. Spain, however, transferred the fibre to Germany and France. Apparently alpaca yarn was spun in England for the first time about the year 1808. It does not appear to have made any headway, however, and alpaca was condemned as an unworkable material. In 1830 Benjamin Outram, of Greetland, near Halifax, appears to have attempted again the spinning of this fibre, and for the second time alpaca was condemned.

These two attempts to use alpaca were failures owing to the style of fabric into which the yarn was woven—a species of camlet. It was not until the introduction of cotton warps into the Bradford trade about 1836 that the true qualities of alpaca could be developed in the fabric. Where the cotton warp and mohair or alpaca weft plain-cloth (usually termed "Orleans") came from is not known, but it was this simple yet ingenious structure which enabled Titus Salt (*q.v.*), then a young Bradford manufacturer, to utilize alpaca successfully. Bradford is still the great spinning and manufacturing centre for alpacas, large quantities of yarns and cloths being exported annually to the Continent, to the United States, to South America and elsewhere, although the quantities naturally vary in accordance with the fashions in vogue. The typical "alpaca-fabric" was originally a very characteristic "dress-fabric" but to-day the fibre is chiefly used for linings.

Owing to the success in the manufacture of the various styles of alpaca cloths attained by Sir Titus Salt and other Bradford manufacturers, a great demand for alpaca arose, and this could not be met by the native product, for there never seems to have been any appreciable increase in the number of alpacas available. Unsuccessful attempts have been made to acclimatize the alpaca in England, on the European continent and in Australia, and even to cross certain English breeds of sheep with the alpaca. There is, however, a cross between the alpaca and the llama, termed the "paco-vicuña," (whether a true hybrid is not yet known) producing a material placed upon the Liverpool market under the name "Huarizo." Crosses between the alpaca and vicuña produce a fibre practically equal to the vicuña fibre in softness and fineness, and it is hoped that further attempts will be made to develop this cross. It is often suggested that the wild huanaco crosses with the alpaca; but this is still doubtful, although such supposed crosses are exhibited at shows in Peru. The preparing, combing, spinning, weaving and finishing of alpacas and mohairs are dealt with under WOOL.

(A. F. B.)

The following statistics, taken from the Bradford Chamber of Commerce *Statistics of the Woollen and Worsted Trades of the United Kingdom*, give an idea of the extent of the trade in yarns and fabrics of the alpaca type; unfortunately statistics for alpaca alone are not published.

Alpaca, Vicuña and Llama Wool imported into the British Isles

Year.	Peru.		Chile.*

ALP ARSLAN, or **AXAN**, **MOHAMMED BEN DA'UD** (1029–72), the second sultan of the dynasty of Seljuk, in Persia, and great-grandson of Seljuk, the founder of the dynasty, was born in the year A.D. 1029 (421 of the Hegira). He assumed the name of Mohammed when he embraced the Muslim faith; and on account of his military prowess he obtained the surname *Alp Arslan*, which signifies "a valiant lion." He succeeded his father Da'ud as ruler of Khorassan in 1059, and his uncle Toghrul Bey as sultan of Oran in 1063, and thus became sole monarch of Persia from the river Oxus to the Tigris. In consolidating his empire he was assisted by Nizām ul-Mulk, his

vizier. Peace and security being established in his dominions, he convoked an assembly of the States and declared his son Malik Shah his heir and successor.

With the hope of acquiring immense booty in the rich church of St. Basil in Caesarea, the capital of Cappadocia, he placed himself at the head of the Turkish cavalry, crossed the Euphrates and entered and plundered that city. He then subdued Armenia and Georgia, in 1064. In 1068 Alp Arslan invaded the Roman Empire. The emperor, Romanus Diogenes, assuming the command in person, met the invaders in Cilicia. In three arduous campaigns, the first two conducted by the emperor himself, the third by Manuel Comnenus, the Turks were defeated in detail and finally (1070) driven across the Euphrates. In 1071 Romanus again took the field and advanced with 100,000 men, including a contingent of the Turkish tribe of the Uzes and of the French and Normans, under Ursel of Baliol, into Armenia.

At Manzikert, on the Murad Tchai, north of Lake Van, he was met by Alp Arslan; and the sultan having proposed terms of peace, which were scornfully rejected by the emperor, a battle took place (1071) in which the Greeks, after severe losses, were totally routed, a result due mainly to the rapid tactics of the Turkish cavalry. Romanus was taken prisoner and conducted into the presence of Alp Arslan, who treated him with generosity, and terms of peace having been agreed to, dismissed him, loaded with presents and respectfully attended by a military guard. Alp Arslan now prepared to march to the conquest of Turkistan, the original seat of his ancestors. With a powerful army he advanced to the banks of the Araxes (Oxus). Before he could pass the river with safety it was necessary to subdue certain fortresses, one of which was for several days vigorously defended by the governor, Yussuf Kothual, a Kharizmian. He was, however, obliged to surrender and was carried a prisoner before the sultan, who condemned him to a cruel death. Yussuf, in desperation, drew his dagger and stabbed the sultan, who died within a few hours (Dec. 15, 1072).

See Gibbon, *Decline and Fall of the Roman Empire*, ed. by J. B. Bury (1898), vi. pp. 235 *et seq.*, and authorities there cited.

ALPENA, a city of Michigan, U.S.A., on Thunder bay, a small arm of Lake Huron, at the mouth of Thunder Bay river, the county seat of Alpena county. It is served by the Detroit and Mackinac and the Boyne City, Gaylord and Alpena railways, and by steamboats to Detroit and other ports. The population in 1920 was 11,101, 2,506 foreign-born whites; 1930, 12,166. The city is built on sandy ground on both sides of the river and has a good harbour, with a controlling depth of 16 feet. The navigation season is from April 3 to Dec. 20.

In 1927 the commerce of the port, chiefly in coal, cement, stone, and lumber, amounted to 1,561,481 tons, valued at \$8,410,286; and the output of the 24 factories, producing chiefly lumber, shingles, wood pulp, veneer, excelsior, brick, cement, leather and flour was valued at \$7,982,697. The city has extensive fisheries, and is a summer and hunting resort. It occupies the site of an Indian burying-ground. A trading post was established here in 1835, a permanent settlement in 1858, and the city was chartered in 1871. It has a commission manager form of government.

ALPENHORN, ALPHORN, a musical instrument, consisting of a natural wooden horn of conical bore, having a cup-shaped mouthpiece, used by mountaineers in Switzerland and elsewhere. The well-known *Ranz des Vaches* is the traditional melody of the alpenhorn, a portion of which is utilized by Beethoven in the finale of the *Pastoral Symphony*. Rossini also introduced the melody in his opera *William Tell*. The Swiss alpenhorn varies in shape according to the locality.

ALPES MARITIMES, department of south-east France, formed in 1860 out of the county of Nice, to which were added the districts of Grasse (formerly in the department of the Var) and of Mentone (purchased from the prince of Monaco). Pop. (1906) 334,007; (1926) 435,253. It is bounded north-east by Italy, south by the Mediterranean sea, and west by the departments of Var and Basses Alpes. Area, 1,444 sq.m. It is composed mainly of the valleys of the Var and its affluents, the Tinée and the Vésubie. Most of the department is mountainous, Mont

Tinibras at the head of the Tinée valley reaching nearly 10,000 ft. The Italian frontier here is peculiar. The centre of the Roja valley is French; the upper and lower parts are Italian because they formed part of the county of Ventimiglia; the central section, part of the county of Nice, alone became French in 1860. It is thus impossible to have an Italian railway from Cuneo by the Col de Tenda and down the Roja valley direct to Ventimiglia. From near Isola in the upper Tinée valley southwards the political frontier is not the main Alpine watershed; the reason (it is said) is that in 1860 all the higher valleys of the Maritime Alps (on both sides of the watershed) were expressly excepted from the treaty of cession, in order that Victor Emmanuel II. might retain his right of chamois hunting in these parts. The department is divided into two arrondissements (Nice and Grasse), 28 cantons and 156 communes. It forms the bishopric of Nice (the first bishop certainly known is mentioned at the end of the 4th century), which till 1792 was in the ecclesiastical province of Embrun, then (1802) in that of Aix en Provence, next in that of Genoa (1814) and finally (1860) in that of Aix again. Its chief town is Nice. The broad-gauge railways in the department cover 56m., including the line along the coast, while there are also 82m. of narrow-gauge railways. The chief industries are the distilling of perfumes and manufacture of olive oil, of pottery and of tiles, besides a great commerce in cut flowers. To foreigners the department is best known for its winter resorts, Nice, Cannes, Mentone, Antibes and Beaulieu, while other important towns are Grasse and Puget Théniers.

ALPHA and **OMEGA** (Α and Ω), the first and last letters of the Greek alphabet (Rev. i. 8, xxi. 6, xxii. 13). The Speaker never claims to combine in Himself all and every power. So in Rabbinic writers the word Emeth (Truth, אמת), which is composed of the first, middle and last letters of the Hebrew alphabet, is the seal of God.

ALPHABET. The name alphabet is derived from the names of the first two letters of the Greek alphabet, *alpha* and *beta*, and denotes a set of characters, or, as we call them, letters, each of which represents a given sound or sounds. This representation is necessarily rough and of quite a general character. This is easily seen in the case of the first letter of the English alphabet, for example, which represents different sounds in the words *father*, *man* and *take*. But even in cases where a letter is regarded as representing a single sound, it does so roughly, taking no account of differences of intonation, tone or pitch, nor of stress, nor of slight variations of pronunciation which vary not only between one individual speaker and another, but also from time to time in the case of an individual in accordance with the position of a given sound in a word, of a word in a phrase, or with the nature of the phrase to which he is giving utterance. In this connection writing stands in much the same relationship to speech as speech does to thought. If language is not a sufficiently delicate instrument to express the nuances of human thought, writing is a less delicate instrument still, and any attempt to multiply signs and characters to keep pace with the subtle variations of the human voice would only impair their usefulness.

An alphabet is a highly-developed, artificial form of writing. The connection between sound and character is conventional and not essential. This is not the case with all forms. Pictographs (see PICTOGRAPHY), ideographs (*q.v.*), and hieroglyphs (*q.v.*) are forms of writing the characters of which bear an essential relationship to what they are intended to represent. Such methods constitute generally speaking an earlier stage in the development of writing than syllabaries and alphabets, which have passed into the conventionalized stage. An earlier stage still may be found in the various devices employed to assist memory, such as the notched stick, notched in the presence of the messenger to whom the significance of each notch is verbally emphasized, a method not far removed from the tying of a knot in the handkerchief (see KNOTS). Again there are the Peruvian Quipus (*q.v.*), notched sticks from which strings are suspended of varying colour and length, knotted in various places, each variation having its own significance; or the North American Indian custom of adorning deerskin belts with wampum beads (see WAMPUM), whose colour

CHART ILLUSTRATING THE PRESUMED DEVELOPMENT OF THE MODERN EUROPEAN ALPHABET FROM THE BRAHMI LETTERS OF INDIA

and position were employed to described historical events such as battles, or even the terms of treaties, with remarkable accuracy to those who knew the secret of their elucidation. There are thus three distinct stages in the growth of writing, though they need not necessarily be thought of as hard and fast chronological stages.

Picture-writing or the use of the ideograph is the intermediate of the three stages. An ideograph (*q.v.*) is a drawing representing not a sound, nor even a word, but an idea. Thus the drawing of a man with protruding ribs represents famine; or an eye with tears dropping from it, sorrow. Till recently such methods of communication were in use among certain tribes of North American Indians. They appear to have been so among many races in various regions.

In this connection should be mentioned the writing known as Nsibidi or Nchibiddi in use among a secret society or club among the Ekoi people of southern Nigeria. The writing is purely ideographic, but the symbols are conventional, fixed in form and

meaning. The script is jealously guarded by the members of the secret society. Its origin is unknown; but certain resemblances have been detected to the Egyptian hieroglyphic system, one of the most remarkable being that the Nsibidi picture-symbol for *house* is rectangular in shape, whereas all dwellings among the people who use it to-day are, and have been for centuries, round. Moreover the Ekoi people are semi-Bantu in descent, and there is reason to suppose that the Bantu peoples migrated from the lower Nile regions. (For an account of this writing see *In the Shadow of the Bush* by P. Amaury Talbot, Appendix G. p. 447 ff.)

Six different peoples in various parts of the world developed a system of writing usually known as transitional, that is to say, they continued the use of the ideograph, but added symbols of a purely phonetic value, and made use of the two side by side. These peoples were the Sumerians and Babylonians, whose cuneiform was a script of this nature, the Egyptians, the Hittites, the Chinese in the Far East, and in America the Mayas and Aztecs.

The method by which this change took place was, generally speaking, that the picture-symbol representing any given object, an eye, for example, came to represent the same sound under all circumstances, as if for instance the drawing of an eye came to stand not only for the meaning *eye*, but also for the pronoun *I*, which has the same phonetic value. This could be the case not only when the sound constituted a whole word, but when it occurred as a single syllable within a word. Even in purely pictographical writing something of the sort occasionally took place. The Mexican name *itz-coatl* meaning literally *snake-knife* and represented by the drawing of a snake surrounded by knives, occasionally occurs as *itz-co-atl* with a different picture, *co* meaning a pot. Though this process is of a different nature, it serves as an illustration of the tendency to connect the drawing not only with the object it essentially represented but also with any homonym of that object. This being so, it became the custom to draw or write the picture with greater haste and carelessness, time being more important than accuracy, so soon as the symbol came to represent not an object but a sound. A badly-drawn eye, for example, will serve perfectly well for a sound that covers both words *eye* and *I*. There is no longer need for the drawing to be recognizable as an *eye* when it is no longer required to represent the object to the sight, but only a sound which itself carries meaning to the ear. Thus picture-writing degenerated, the process being a distinct gain in ease of communication. It was in this way that the Egyptian hieratic and demotic scripts came into existence, although so strong was the habit of writing hieroglyphs that for many centuries both were employed side by side, even literally so in the same piece of writing, the hieroglyph sometimes actually following the phonetic symbol in order, as it were, that the meaning might be doubly assured.

The Chinese ideographic system exhibits peculiarities which depend upon the language that it was formed to represent. So soon as the symbols attained a phonetic value, serious difficulty arose from the fact that a single monosyllabic word might have many distinct meanings, distinguished in speech only by intonation which it was, for a time, impossible to represent in writing. The difficulty was felt in the spoken language also, and one homonym was distinguished from another by the addition of a second word which made the meaning clear, a kind of compound being thus formed. In the course of time the original pictographs have deteriorated, but they are capable of analysis into their original constituent parts without undue difficulty (*see CHINESE LANGUAGE*).

The Japanese, when they came into contact with Chinese civilization in the 5th century A.D., adopted the Chinese phonographic script and endeavoured to adapt it to their language. Finding, however, that their chief sounds could be comprehended in a syllabary of 47 characters they developed these from Chinese characters. For literary or learned purposes the Chinese phonograms are still in use among them, so that in spite of the utter difference of language the Japanese and Chinese can communicate by means of writing, although each symbol has a totally different phonetic value to the speakers of either language. The neighbouring countries of China, Japan and Korea exhibit three separate modes of writing, ideographic, syllabic and alphabetical, the Koreans having invented an alphabet based on Sanskrit forms.

The syllabary and alphabet are examples of the most highly-developed stage of writing, the conventional stage, when there is no essential connection between sound and symbol. To some peoples the development of a syllabary seemed to come more easily than that of an alphabet. A syllabary existed in Cyprus in ancient times. In the case of a language that for reasons of phonetic decay or otherwise has multiplied consonants in a single syllable the syllabary is a cumbersome mode of writing. The word *strength*, for example, would have to be written *as-at-ar-eng-ath*, or *sa-ta-re-nga-tha* and this is obviously a representation of the sounds composing the word that is far from adequate. It will also be readily seen that a much greater number of symbols is required for a syllabary than is the case with the far more convenient alphabet.

The alphabet then is the form of writing that to those peoples

who have developed, borrowed or adopted it has been found the most convenient and adaptable. Its use is acquired in childhood with ease, which is far from being the case with the Chinese phonograms, for instance. It may also be passed from one language to another without difficulty. The history of our own alphabet, which has survived as an alphabet with, all things considered, surprisingly little change for nearly 3,000 years and is

still vigorous, untouched by the introduction of printing or of the typing machine, demonstrates its suitability to the needs of the many languages it has served.

The story of our alphabet from the time that we first find it employed in the earliest known Greek inscriptions is not hard to trace. It is its history in its pre-Greek days that is still wrapped in doubt. The Greek names for its letters, *alpha*, *beta*, *gamma*, *delta*, etc., demonstrate its Semitic origin, for though the names may not in every case have a Semitic etymology, they correspond closely with the Semitic names (*cf.* the Hebrew *aleph*, *beth*, *gimel*, *daleth*). Two questions have hitherto remained unanswered. How did the Greeks obtain it from the Semites? And what was its pre-Semite history? In recent years decided advances have been made towards a solution of either question.

Until rather more than ten years ago the earliest known examples of the Semitic alphabet were what is known as the Moabite Stone, an inscription of Mesha king of Moab dating from the 9th century B.C., and a votive inscription to Baal-Lebanon discovered in Cyprus. Various theories have been current as to

the origin of the Semitic alphabet, the earliest being the view of Lenormant, published by De Rougé in 1874, that Egypt was its starting-place. Others attempted to connect it with Babylonian cuneiform, with the Cyprian syllabary, or with the Minoan writing of Crete. The latter is the view of Sir Arthur Evans who, in his great work *Scripta Minoa*, develops the theory that the alphabet was taken from Crete to Palestine by the Philistines and from

The Safahitic inscriptions come from rocks in the district of Safah near Damascus. Most of the south Semitic inscriptions read from right to left but a few are written *βουστροφῆδον*, as the Greeks said, that is to say, from right to left and left to right in alternate lines. There are 29 letters in the Sabaeen alphabet. The date of the earliest Sabaeen inscriptions appears to be about the 6th century B.C., and most of those who have noticed them are agreed that this alphabet descends not from that of the Moabite Stone but from an older source common to both. Dr. Alan Gardiner sees this source in the alphabet of the Sinai inscriptions. Two or three of the signs, notably that for *beth*  in Sabaeen, for *phē*  in Sabaeen, and for *thau*  in Thamudenic and Safahitic resemble symbols of the Sinai script. But it would be difficult to derive most of the signs from any found there. Further, Dr. Gardiner's identification of the Sinai symbols does not rest upon a completely sure basis in the absence of a certain interpretation of the inscriptions. Dr. Gardiner sees the most important line of evidence in the names of the letters. Of the 22 letters of the Semitic alphabet 17 have Semitic names, which are the names of ordinary objects. Five are unintelligible. It is obvious that the simplest interpretation of the fact of these names is that the letters were once picture-symbols representing the object whose name the alphabetical symbol has retained. In 15 cases symbols appear on the Sinai inscriptions which evidently represent objects to which these names belong. It is therefore no far-fetched conclusion to regard these symbols as prototypes of the alphabetical symbols which continued to bear the names of the objects they represent. There is also no doubt of the close connection of the symbols of the Sinai script with certain Egyptian hieroglyphics, and it is scarcely probable that identical picture symbols would have developed independently in Egypt and so near to its borders as to be in use in the Sinai peninsula. The close intercourse between Egypt and regions lying beyond Sinai render complete independence of script unlikely. On the other hand, of 32 separate characters apparently employed in the Sinai inscriptions, 17 are unintelligible, not being found to correspond sufficiently closely either with Egyptian hieroglyphic characters on the one hand nor letters of the Semitic alphabets on the other. The accompanying table, taken from that drawn up by Dr. Alan Gardiner to illustrate his article shows the relationship between the Egyptian hieroglyphs, the Sinai script, the alphabet of the Moabite Stone, the south Semitic alphabets, and that of early Greece. While Dr. Gardiner's interpretation of this script cannot be said to have proved that Egypt was the original home of the Semitic alphabets, it has directed attention to Egypt as deserving serious consideration as a claimant to this honour.

A different view of the origin of both the Phoenician and Greek alphabets is offered by Prof. Sir W. Flinders Petrie who in 1912 published his book *The Formation of the Alphabet*. In this he argues that both these alphabets together with those of Asia Minor, the south Semitic, Cyprian and certain Egyptian scripts developed from a series of conventional marks or signs employed for commercial purposes throughout the Mediterranean area from earliest times. "In Egypt, especially," he says, "the monumental evidence shows two entirely different sources of conventional marks. In late times the picture writing passed through many stages, until it became the complex grouping of slightly varying strokes in the demotic writing. But far before all this there had existed, from the beginning of the prehistoric ages, a totally different system of linear signs, full of variety and distinction. This early system was certainly in its decadence long before any hieroglyphs were used in Egypt. Similarly in Crete a system of linear signs precedes the pictographic records." But Professor Petrie is alone, or practically so, in supposing that the early marks to which he refers had any significance, and his theory of the development of various local alphabets from such marks has not found general acceptance. Too many links are missing in the chain of proof. The fact that identical alphabetical symbols occur in widely distant regions of the Mediterranean area, which he stresses, is capable of other explanations.

The most important fact ignored by any theory that would derive the Greek and Phoenician alphabets independently from a

them borrowed by the Phoenicians. The Egyptian view was revived in 1916 in a paper published in the *Journal of Egyptian Archaeology*, vol. iii. (1916) p. 1 ff., by Dr. Alan Gardiner. This paper deals with certain inscriptions discovered in 1906 by Sir W. Flinders Petrie in the Sinaitic peninsula, in which Dr. Gardiner sees a stage of writing intermediate between Egyptian hieroglyphic and the Semitic alphabet. The script appears to be fully alphabetic, and the date of the inscriptions is not later than 1500 B.C. These inscriptions have also been dealt with by Hans Bauer (*Zur Entzifferung der neuentdeckten Sinaischrift*, Halle, 1918), who is inclined to see in the script a prototype of the Semitic alphabets, independent of Egypt.

For a solution of the question the evidence of the four south Semitic alphabets must be considered. These are known as Sabaeen, Lihyanic, Thamudenic and Safahitic. Inscriptions in these south Semitic alphabets were discovered in considerable numbers during the course of the 19th century. Those in the Sabaeen alphabet come from the district of Yemen in south Arabia, the Lihyanic from El-Ola in the north of the Hejaz,

source older than either is that the names of the letters, as far as they have a known etymology or meaning, are Semitic. Hebrew *aleph*, *beth*, *gimel*, *daleth*, etc., correspond unmistakably with Greek *alpha*, *beta*, *gamma*, *delta*. The Semitic names are words in the Semitic languages. The Greek names are meaningless in Greek. It has indeed been argued that the Greek names were the original ones, meaningless, and taken in the first instance simply from the sounds represented by the letters; that the Phoenicians took over the alphabet together with the names from the Greeks and adapted the names by the process known as folk-etymology. But the Sinai inscriptions, discussed above, may be said to have rendered this theory untenable. If they do not represent a link between the hieroglyphic system of Egypt and the Phoenician alphabet, they represent a prototype of the latter, appearing at a date and at a place that render any theory of borrowing from Greek sources highly improbable. It is reasonably certain that the Greeks derived their alphabet from Semitic sources, taking over the names with the letters. The names are not identical. The Greek names end with a vowel—*alpha* for *aleph*, *beta* for *beth*, etc. The vocalization has been explained merely as being more in agreement with Greek morphology, but this is not a very definite or satisfactory explanation. Isaac Taylor had already pointed out in the *History of the Alphabet* (1883) vol. ii. p. 27 that the Greek forms are taken from *Aramaic*, Aramaic showing an emphatic form of the root which ends in a vowel and drops the vowel in the preceding syllable. He postulated two separate borrowings of the alphabet by Greeks, the earlier being the Chalcidic alphabet borrowed with the Babylonian system of weights and coinage from Aramaic peoples in the south-eastern extremity of Asia Minor, possibly through Lydia; the second the borrowing by the Ionians directly from Phoenician traders. The Aramaic names came with the first borrowing and were carried on and applied by the later borrowers. These two forms of the alphabet, Chalcidic and Ionic, generally known as western and eastern, represent two different borrowings, but we may probably rule out the theory of any direct borrowing from Phoenician sources. The tradition that this was so comes from Herodotus, who refers only to Boeotia, and it is probable that the name *Phoenices* was a vague term for eastern foreigners. The Achaeans were a naval power settled in the eastern Aegean in the 15th century B.C. There is therefore no difficulty in concluding that they borrowed the alphabet from peoples with whom they were in close contact in western and southern Asia Minor at a considerably earlier date than has hitherto been supposed; nor that, independent as Greek States were, there were separate borrowings and separate adaptations.

The chief adaptations made by the Greeks were the allocation of certain of the 22 Semitic letters to vowel-sounds, and the addition of certain letters. The oldest extant Greek inscriptions are those found in 1896 in the island of Thera, which date from the 8th, possibly even the 9th, century B.C., the inscriptions from Abu Simbel in Upper Egypt, dating from the 7th century, a Corinthian and an Athenian inscription of the 6th century. In Thera the oldest inscriptions are written from right to left, others are *βουστροφηδόν*, others still later read from left to right. In the Lydian alphabet, known to us by inscriptions found at Sardis in the beginning of the present century, these symbols also represent vowels. Most Greek States developed local variations either in the forms of certain letters, or in the representation of sounds not represented by any of the 22 letters taken over. The two main divisions, eastern and western, however, remain till the 4th century B.C., when in the main uniformity of alphabet was attained throughout Greece. The early inscriptions from Thera show a remarkably close resemblance to the forms of the Semitic alphabet as represented on the Moabite Stone or the Baal-Lebanon inscription from Cyprus. The alphabet of Abu-Simbel is of the Ionic type.

The two main divisions, eastern and western, again sub-divide into two, the cities of Asia Minor and the adjacent islands with their colonies using forms showing in some cases slight differences from those in use in the Cyclades and Attica. Again the alphabets of Megara, Corinth, Sicyon, Phlius and western Argolis with

their colonies differ from the west which includes Euboea, Boeotia, Phocis, Locris, Thessaly and the rest of the Peloponnese. Throughout all Greek alphabets the Semitic letters *aleph*, *he* and *ayin*, which represented breathings, were adapted to represent vowels. *Alpha* (*aleph*) was consistent throughout. The letter corresponding to Semitic *he* (later *epsilon*) represented both the short and long vowel *e* in those cases where *eta* represented the rough breathing. Generally speaking *eta* represented the vowel-sound in the eastern alphabet, the breathing in the western. Thus in the west the symbol *Ε* or *Ε* is used for the two sounds represented in Attic by *ε* and *η*; in the east it more usually represents the short vowel alone. In addition to this, however, it is occasionally used throughout to represent the long close *ē* (the long *ē* represented by *eta* was open), which in Attic is written as if it were a diphthong, *eu*. The Corinthian alphabet is peculiar in using (up to the 6th century and later in outlying regions) the sign *Β* or *Β* to represent *e*, the long close vowel being written *ΒΣ*. Sicyon uses a symbol with the form *Σ*. Semitic *cheth*, Greek *eta*, was

CHART SHOWING VARIOUS ROMAN FORMS OF THE ALPHABET

used, as we have seen, in the east generally speaking as a vowel, in the west as the rough breathing. In the Thera inscriptions, it occurs in both capacities. The semi-vowel *j* (resembling the sound of English initial *y*) had disappeared from the Greek language in prehistoric times, degenerating into a rough breathing, so that Semitic *yod* was adapted in Greek to represent the vowel *i* (iota). *Koppa* (Ϟ) had disappeared in the eastern alphabets by the 5th century B.C., its place being usurped by *kappa* (κ),

but it lingered in the west and was introduced into the Italic alphabets, as we shall see.

The origin of the *digamma* (F, representing the *w* sound) is obscure. *Vau*, the sixth letter of the Semitic alphabet, was taken by the Greeks for use as a vowel, exactly as they had taken *yod*, and placed at the end of the alphabet following *tau*. But whereas the consonantal *i*-sound did not exist in Greek, the consonantal

The usual manner of expressing this combination in the Aegaeon islands was **XS**. The letter **X**, which often appears in the west as **+**, may be a direct descendant of **𐤃** (*samech*), and quite independent of **X** or **+**, the 26th letter of the Greek alphabet, the origin of which is unknown. The sibilant *s* was expressed by two separate symbols, **𐤌** and **𐤍** or **Σ**, the one descended from Semitic *ssade*, the other from Semitic *san*. Both do not appear in the same alphabet. **𐤌** appears in Crete, Thera and Melos, in Phocis in the 6th century, elsewhere only in the Peloponnese and its colonies. In two 5th century inscriptions from Teos and Halicarnassus a form **T** appears with the value *σσ*. The unvoiced velar aspirate was expressed by a form **X** or **+**, which became the 26th letter of the alphabet in practically all alphabets except in the western group. The same form was used in the west for the *x*-sound, and here it was probably a descendant of Semitic *samech* **𐤃**. In the west where **X** was used for the *x*-sound and not for the unvoiced velar aspirate (*kh*, **X**), the latter was expressed by a symbol **𐤛**. In Boeotia we actually find **𐤛** used in combination with **𐤌** to represent the *x*-sound, a fact that suggests that there was some consciousness that it was used in the west as a substitute for eastern **X**. **𐤛** is used singly to express the *x*-sound in Thera and Melos. In the east, where **X** expressed the *kh*-sound, **𐤛** was used (sometimes with the form **𐤛**) to express the combination *ps*, a use in which it was later standardized by the spread of the Ionic alphabet.

Other symbols not derived from Semitic were (i.) **Φ** (*phi*) used to express the unvoiced labial aspirate (*ph*) and (ii.) **Ω** the last letter of the Greek alphabet, probably differentiated from **O**. In the west this symbol appears very seldom. In the east it represents the long open *o*. In the Cyclades curiously enough it frequently expresses the close vowel, whether long or short (*o* or *ou*) while **O** represents the open sound.

The origin of the symbols **Φ** and **𐤛** is unknown. In the case of **X** or **+** it is probable that we should differentiate **X** derived from **𐤃** and standing for *x* from **X** standing for *kh*. The origin of the latter is however obscure. It is possible that these signs were adapted in Asia Minor from the Cypriote syllabary.

Various local alphabets were in use in Asia Minor that were parallel to the Greek. The Lydian alphabet for instance is known to us from inscriptions dating from the 4th century B.C. A few of these were discovered in the last century, 36 were found by an American expedition in Sardis between the years 1910 and 1913, the rest by J. Keil and von Premerstein in various parts of ancient Lydia between 1906 and 1912. The alphabet consisted of 26 symbols. The parallelism with the Greek and Semitic alphabets is clear, but there are additional symbols the sound of some of which is uncertain in the absence of a completely certain interpretation of the language of the inscriptions. The most interesting fact about this alphabet is the identity of the symbol for *f* **8** with the Etruscan symbol for the same sound.

The western Greek or Chalcidian alphabet was brought to Italian soil by the Greek colonies of Magna Graecia, and until recently it was confidently held that the Latin alphabet, the parent of our own, was derived from this Chalcidic alphabet by contact with the Greek colonies of southern Italy. Too little was made of the influence of Etruria because too little was known of that country and its people. Six Italic alphabets have come down to us. These are the Latin, Faliscan, Etruscan, Umbrian, Oscan and Messapian. The Messapian is purely Greek in origin and was used by a people who were isolated in Calabria and spoke an Illyrian dialect. The Umbrian and Oscan alphabets are derived from the Etruscan. The district in which the Umbrian alphabet was used was east of the Apennines. The Oscan was in Campania. Thus the Latin and Faliscan alphabets were bounded on all three sides by the Etruscan and alphabets derived from it. In these circumstances Etruscan must have exercised a strong influence upon the Latin alphabet, following the impact of Etruscan civilization upon Roman in other directions.

The Etruscan alphabet is known to us from certain tomb inscriptions, from part of an Etruscan book that was used as the

COMPARISON OF THE INDIAN AND SEMITIC FORMS OF THE ALPHABET

y-sound (akin to *w*) survived till classical times in certain dialects and needed a symbol to represent it. Thus the *digamma* took the place of *vau* in the order of the alphabet, but opinions differ as to whence it derived its form. Some hold that it was differentiated from the preceding letter by the omission of one of the horizontal strokes, others that it descends from *vau* (Y). The latter view is rendered less difficult by the fact that **N** occurs as a form of the digamma from Oaxos in Crete. In the absence of further evidence it is impossible to reach any definite conclusion.

The treatment of the sibilants of the Semitic alphabet by the Greeks is complicated. *Zain* was taken over as *zeta*, though its pronunciation in early times is not certain and may have varied throughout the dialects between *dž*, *dz*, *ž* and *z*. The 15th letter of the Semitic alphabet was *Samech* the name of which through its Aramaic form *simcha* became in Greek by metathesis *sigma*. The name, however, was transposed to the 21st letter, which in Semitic was *san*. The letter itself was retained in the eastern or Ionic alphabet with the value *ks* (ξ). In Thera, however, in early times it has the value of *ss*, *x* or *ks*, being expressed by **KM**.

The Latin alphabet of 23 letters (including **Y** and **Z** became extended during the course of the middle ages to our own of 26 by the division of **I** into *i* and *j* and the tripartite division of **V** into *u*, *v* and *w*. *J* developed in the 15th century as an initial (more or-

It only remains to consider briefly certain alphabets which derived from the same source as our own. The alphabets of India are offshoots of the stem. All derive from two sources, *Kharoṣṭhi* and *Brāhmī*. Though attempts have been made to show that the Brāhmī alphabet was developed in India itself without connection with outside sources, this contention cannot be maintained. It has a manifest kinship with the Semitic alphabets. Its origin is obscure; but there seems little doubt that it derives from the south Semitic group of alphabets through contact with Sabataean

COMPARISON OF THE LATIN, GREEK, AND SLAVONIC ALPHABETS WITH THE RUNES

The alphabets in use in Persia, at least from the time of the

Arsacid dynasty onwards, are based upon the Aramaic. Cuneiform was the writing of the Achaemenid empire, but after the Greek conquest Aramaic was introduced and became general. The Pahlavi is the alphabet of the Sassanid kings. The Arsacid and Sassanian alphabets are found together in the liturgical inscription of Hadji-abad, as well as in the Paikuli inscription dating from about 300 B.C. Ernst Herzfeld dates the commencement of Pahlavi in the time of Darius the Great (vd. *Paikuli* p. 73).

Modern Arabic writing has developed from a form of Aramaic used in the land of the Nabataeans, an Arabian people. The oldest record of it now extant is a stèle from Tema, in north-west Arabia, dating from the 5th century B.C. or perhaps earlier. Later inscriptions, known as Nabataean, belong to the period between 9 B.C. and A.D. 75. The *graffiti* on the rocks of Mount Sinai carry the record of the development of this alphabet down to the 3rd century A.D. In the early Mohammedan period two types of Arabic writing existed, known as the Cufic and the *nashki*. The former was discontinued except for formal purposes, where cursive writing could not be employed. The *nashki* is the parent of modern Arabic writing, in which many characters have become so similar owing to the degeneration of the cursive script that it is necessary to distinguish them by diacritical points. The Christians of northern Syria employed a form of Arabic alphabet, known as Estrangelo, and this was taken by Nestorian missionaries into central Asia, becoming the ancestor of a great number of alphabets which spread as far east as Manchuria.

The earliest records of Aramaic go back to about 800 B.C. and were found at Sindjirli in northern Syria. The alphabet at this time differs little from that of the Moabite Stone. Aramaic became by far the most important and widespread of the north Semitic alphabets. It was used in Assyria as a cursive script side by side with cuneiform. It is marked by two distinct tendencies: (i.) the opening of the heads of the letters, *beth* (𐤁) becoming *y*, *daleth* (𐤃) *y* and *resh* (𐤅) *y*. *o* became *u*, then *v*; (ii.) angles became rounded and ligatures developed. These tendencies were completed during the Persian period, and they are emphasized in the Aramaic writing on papyrus employed in Egypt between 500 and 200 B.C. Other developments of Ara-

Greek, and an Armenian Christian literature thus arose. It is likely that the origin is Greek, a few Persian characteristics that appear being due to the influence of the dominating power.

In all Teutonic countries are found inscriptions in the alphabet known as Runic. The affinities of this alphabet with the Greek are apparent, but there has been dispute as to whether it is derived directly from Greek or through an Italic alphabet. The strongest argument in favour of a Latin derivation is the fact that the value of the letter *W* is *f*, not *w*. L. F. A. Wimmer in his book *Die Runenschrift* (1887) contended strongly for a Latin origin. He believed that the Runes developed from the Latin alphabet at the end of the 2nd century A.D. This can scarcely be the case however, for the Romans had been in contact with the Germanic tribes for some time before this date, and the alphabet, if borrowed from them, would thus have been borrowed sooner. Again many Runic inscriptions are written from right to left or *βοστροφηδόν* and this would have been impossible had the alphabet been borrowed from one uniformly written from left to right. Others have concluded with more probability that the Runes are derived directly from a western Greek alphabet resembling that which appears on the Formello abcdaria. It is possible that knowledge of such an alphabet reached northern Europe from Italy through the medium of Etruscan traders. This might account for the value of *W*; Isaac Taylor's view was that the alphabet was derived from a Greek colony on the Black Sea about 600 B.C. Of the two views this is perhaps the more probable. It may even be that the alphabet was derived in the region of the Black Sea not directly from a Greek, but from an Asianic source, closely parallel with the Greek developments, as we have already seen the Etruscan alphabet probably to have had its origin. There is some, but not conclusive, evidence that the alphabet was borrowed previous to the Teutonic sound-shift.

An outcome of the Runic alphabet was the cryptographic Ogham writing employed by Celtic peoples in Britain and Ireland (see OGHAM LANGUAGE). In this the several letters of the alphabet were represented by strokes differing in number (from one to five) and in position on either side, or on both sides, of a straight horizontal line.

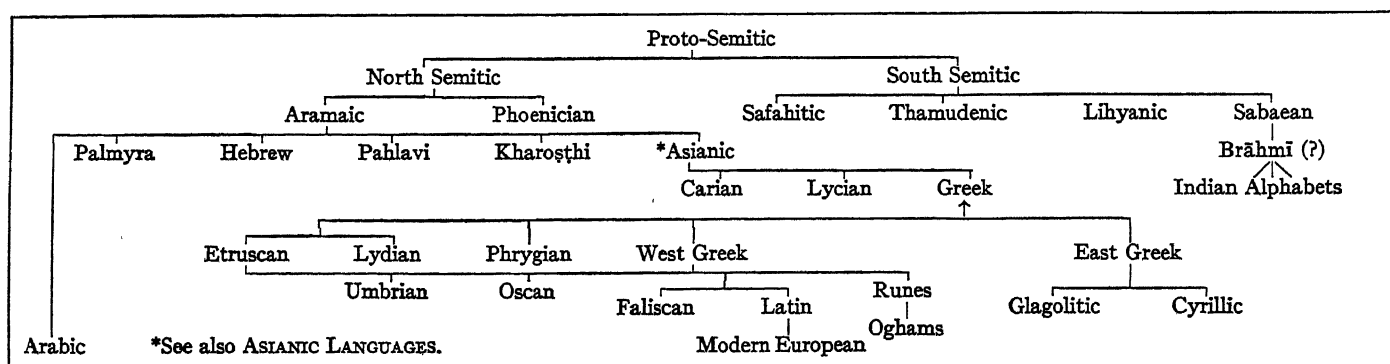

maic are modern square Hebrew and the alphabet of Palmyra.

A group of alphabets arose in Asia Minor during the first half of the first millennium B.C. deriving from a common source, probably an early stage of Aramaic. The Greek alphabet in its two varieties was one of these. The Carian alphabet was another, as also the Lycian. These both seem parallel to Greek, not offshoots of it. The Phrygian on the other hand seems to be derived from the Greek, and from the western variety.

The Armenian alphabet owes its origin to Bishop Mesrob late in the 4th century A.D. Both an Iranian and a Greek origin have been claimed for it, Isaac Taylor contending for the former, Gardthausen and Hübschmann for the latter. The country had been divided between Persia and the Byzantine empire. The larger share fell to the Persians who discouraged the study of

The date of these inscriptions in Wales is the 5th and 6th centuries A.D.

Finally must be mentioned the two Slavonic alphabets, Cyrillic and Glagolitic, both according to tradition the invention of Cyril, the missionary to the Slavs, in the 9th century A.D. Each is taken from the Greek alphabet of that period, Glagolitic from the cursive writing, Cyrillic from uncial, when the value of *B* had become the spirant *v*, that of *H* *i*, of *Φ* *f* and of *Χ* the sound of Scotch *ch*. Several additional symbols were invented to express those sounds of the Slavonic language which could not be comprised within the compass of the Greek alphabet. Glagolitic survived in Croatia till the 17th century. Cyrillic has for long been the alphabet in which the Slavonic languages are normally expressed.

ALPHA PARTICLES, also called α -rays, the positively charged particles that are ejected by certain radioactive substances. (See RADIOACTIVITY.) They are helium atoms (see ATOM) which have lost one or two electrons (see ELECTRON) and are identical with the ionized helium which is produced by an electric discharge through this gas. (See POSITIVE RAYS; and ELECTRICITY, CONDUCTION OF: in Gases.)

'AL-PHASI, ISAAC (1013-1103), Jewish rabbi and codifier, known as *Riph*, was born near Fez, and died at Lucena. He settled in Spain. His fame rests on his Talmudical Digest, which omitted all homiletical passages and also passages relating to religious duties practicable only in Palestine. He occupies an important place in the development of the Spanish method of studying the Talmud. As opposed to the French rabbis, the Spanish sought to simplify the Talmud, and to free it from casuistical detail. His Digest was the forerunner of the great Codes of Maimonides and of Joseph Caro.

ALPHEGE (AELFHEAH) ST. (954-1012), archbishop of Canterbury. He was a monk at Deerhurst, and then became an anchorite at Bath. His piety and austerities led to his election as abbot. In 984 he was appointed through Dunstan's influence to

the bishopric of Winchester, and in 1006 he succeeded Aelfric as archbishop of Canterbury. At the sack of Canterbury by the Danes in 1011 Aelfheah was captured and kept in prison for seven months. Refusing to pay a ransom he was barbarously murdered at Greenwich on April 19 1012. He was buried in St. Paul's, whence his body was removed by Canute to Canterbury with all the ceremony of a great act of State in 1023.

Lives of St. Alphege in prose (which survives) and in verse were written by command of Lanfranc by the Canterbury monk Osbern (d. c. 1090).

ALPHEUS (*Ἀλφειός*; mod. *Ruphia*), the chief river of Peloponnesus. The Alpheus proper rises near Asea in central Arcadia, but its passage thither by subterranean channels from the Tegean plain, and its union with the Eurotas, are probably mythical (W. Loring, *Journ. Hell. Studies*, xv. p. 67). The shallow and rapid stream occupies but a small part of its broad, stony bed. Leaving the plain of Megalopolis by a rugged gorge, it receives above Olympia two large tributaries, Erymanthus and Ladon, from the north-east and empties itself into the Ionian sea. Strictly, Ruphia is the modern name for the Ladon, but the name has been given to the whole river. Pliny states that it was navigable for six Roman miles from its mouth. Alpheus was recognized as the typical river-god in the Peloponnesus, as was Achelous (*q.v.*) in northern Greece. His waters were said to pass beneath the sea and rise again in the fountain Arethusa at Syracuse.

ALPHONSE I. (1103-1148), count of Toulouse, son of Count Raymond IV. by his third wife, Elvira of Castile, was born in the castle of Mont-Pèlerin, Tripoli. He was surnamed Jourdain on account of his having been baptized in the river Jordan. In his tenth year he succeeded to the countship of Toulouse and the marquisate of Provence, but Toulouse was taken from him by William IX., count of Poitiers, in 1114. He recovered a part in 1119, but continued to fight for his possessions until about 1123. He next fought for the sovereignty of Provence against Raymond Berenger I., and by a peace reached in Sept. 1125 Jourdain became absolute master of the regions lying between the Pyrenees and the Alps, Auvergne and the sea.

His ascendancy was an unmixed good to the country, for during a period of 14 years art and industry flourished. Louis VII., for some reason which has not appeared, besieged Toulouse in 1141, but without result. Jourdain was twice excommunicated, but in 1146 he took the cross at the meeting of Vézelay called by Louis VII., and in Aug. 1147 embarked for the East, reaching Acre in 1148. He was poisoned at Caesarea, either the wife of Louis or the mother of the king of Jerusalem having suggested the draught.

See the documentary *Histoire générale de Languedoc* by De Vie and Vaissette, vol. iii. (Toulouse, 1872).

ALPHONSE (1220-1271), Count of Toulouse and Poitiers, the son of Louis VIII., king of France, and brother of St. Louis, was born on Nov. 11 1220. He joined the county of Toulouse to his appanage of Poitou and Auvergne, on the death, in Sept. 1249, of Raymond VII., whose daughter Jeanne he had married in 1237. He took the cross with his brother, St. Louis, in 1248 and in 1270. In 1252, on the death of his mother, Blanche of Castile, he was joint regent with Charles of Anjou until the return of Louis IX., and took a great part in the negotiations which led to the treaties of Abbeville and of Paris (1258-59). His main work was on his own estates. There he repaired the evils of the Albigensian war and made a first attempt at administrative centralization, thus preparing the way for union with the crown. The charter known as "Alphonsine," granted to the town of Riom, became the code of public law for Auvergne. He died without heirs on his return from the 8th crusade, in Italy, probably at Savona, on Aug. 21 1271.

See B. Ledain, *Histoire d'Alphonse, frère de S. Louis et du comté de Poitou sous son administration* (1241-71) (Poitou, 1869); E. Boutaric, *Saint Louis et Alphonse de Poitiers* (Paris, 1870); A. Molinier, *Étude sur l'administration de S. Louis et d'Alphonse de Poitiers* (Toulouse, 1880); and also his edition of the *Correspondance administrative d'Alphonse de Poitiers* in the *Collection de documents inédits pour servir à l'histoire de France* (Paris, 1894 and 1895).

ALPHONSINE TABLES, astronomical tables produced at Toledo in 1252 by 50 astronomers under the patronage of Alphonso (Alfonso) X. of Castile.

ALPHONSO, the common English spelling of Affonso, Alonso and Alfonso, which are respectively the Galician, the Leonese, and the Castilian forms of Ildefonso (Ildefonsus), the name of a saint and archbishop of Toledo in the 7th century. The name has been borne by a number of Portuguese and Spanish kings.

ALPHONSO I. (1104-1134), King of Aragon, is sometimes counted the seventh in the line of the kings of Leon and Castile. A passionate fighting-man (he fought 29 battles against Christian or Moor), he was married to Urraca, widow of Raymond of Burgundy, a very dissolute and passionate woman. The marriage had been arranged by Alphonso VI., in 1106, to unite the two chief Christian states against the Almoravides, and to supply them with a capable military leader. But Urraca was tenacious of her right as proprietary queen, and had not learnt chastity in the polygamous household of her father. Husband and wife quarrelled with the brutality of the age, and came to open war. Alphonso had the support of one section of the nobles who found their account in the confusion. Being a much better soldier than any of his opponents he gained victories at Sepúlveda and Fuente de la Culebra, but his only trustworthy supporters were his Aragonese, who were not numerous enough to keep down Castile and Leon. The marriage of Alphonso and Urraca was declared null by the pope, as they were third cousins. The king quarrelled with the Church, and particularly with the Cistercians, almost as violently as with his wife. As he beat her, so he drove Archbishop Bernard into exile and expelled the monks of Sahagun. He was finally compelled to give way in Castile and Leon to his stepson, Alphonso, son of Urraca and her first husband. The intervention of Pope Calixtus II. brought about an arrangement between the old man and the young. Alphonso the Battler won his great successes in the middle Ebro, where he expelled the Moors from Saragossa; in the great raid of 1125, when he carried away a large part of the subject-Christians from Granada; and in the south-west of France, where he had rights as king of Navarre. Three years before his death he made a will leaving his kingdom to the Templars, the Hospitallers, and the Knights of the Sepulchre; this his subjects refused to carry out. He was a fierce soldier and nothing else; his piety was wholly militant; but, though he died in 1134 after losing to the Moors at Braga, he has a great place in the reconquest.

ALPHONSO II., King of Aragon (1162-1196) was the son of Raymond Berenger, count of Barcelona, and of Petronilla, niece of Alphonso the Battler, and daughter of Ramiro, surnamed the Monk. He succeeded to the county of Barcelona in 1162 on the death of his father, at the age of 11, and in 1164 his mother renounced her rights in Aragon in his favour. Though christened Ramon (Raymond), the favourite name of his line, he reigned as Alphonso out of a wish to please his Aragonese subjects, to whom the memory of the Battler was dear. As king of Aragon he took a share in the work of the reconquest, by helping his cousin, Alphonso VIII. of Castile, to conquer Cuenca, and to suppress one Pero Ruiz de Azagra, who was endeavouring to carve out a kingdom for himself in the debatable land between Christian and Mohammedan. But his double position as ruler, both north and south, of the eastern Pyrenees, distracted his policy. In character and interests he was rather Provençal than Spanish, no enemy of the Albigensian heretics, a favourer of the troubadours and himself a poet in the southern French dialect.

ALPHONSO III. of Aragon (1285-1291), the insignificant son of the notable Peter III., succeeded to the Spanish and Provençal possessions of his father, but his short reign did not give him time even to marry. His inability to resist the demands of his nobles and his recognition of their right to rebel in the articles called the Union helped to make anarchy permanent in Aragon.

ALPHONSO IV. of Aragon (1327-1336) was a weak man whose reign was insignificant.

ALPHONSO V. of Aragon (1416-1458), surnamed the Magnanimous, who represented the old line of the counts of Barcelona only through women, and was, on his father's side, descended from the Castilian house of Transtamara, is one of the most conspicuous figures of the early Renaissance. No man of his time had a larger share of the quality called by the Italians of the day "virtue." By

hereditary right king of Sicily, by the will of Joanna II. and his own sword king of Naples, he fought and triumphed amid the exuberant development of individuality which accompanied the revival of learning and the birth of the modern world. When a prisoner in the hands of Filippo Maria Visconti, duke of Milan, in 1435, Alphonso persuaded his ferocious and crafty captor to let him go by making it plain that it was the interest of Milan not to prevent the victory of the Aragonese party in Naples. Like a true prince of the Renaissance he favoured men of letters, whom he trusted to preserve his reputation to posterity. His devotion to the classics was exceptional even in that time. He halted his army in pious respect before the birthplace of a Latin writer, carried Livy or Caesar on his campaigns with him, and his panegyrist Panormita did not think it an incredible lie to say that the king was cured of an illness by having a few pages of Quintus Curtius read to him. The classics had not refined his taste, for he was amused by setting the wandering scholars, who swarmed to his court, to abuse one another in the indescribably filthy Latin scolding matches which were then the fashion. Alphonso founded nothing, and after his conquest of Naples in 1442 ruled by his mercenary soldiers, and no less mercenary men of letters. His Spanish possessions were ruled for him by his brother John. He left his conquest of Naples to his bastard son Ferdinand, his inherited lands, Sicily and Sardinia, going to his brother John.

ALPHONSO I. (1094-1185), the first of the PORTUGUESE KINGS, son of Henry of Burgundy, count of Portugal, and Teresa of Castile, succeeded his father in 1112, and was placed under the tutelage of his mother. Being proclaimed sole ruler of Portugal in 1128, he defeated his mother's troops near Guimaraes, making her at the same time his prisoner. He also vanquished Alphonso Raymond of Castile, his mother's ally, and thus freed Portugal from dependence on the crown of Leon. Next turning his arms against the Moors, he obtained, on July 26, 1139, the victory of Ourique, and immediately after was proclaimed king by his soldiers. He assembled the Cortes of the kingdom at Lamego, where he received the crown from the archbishop of Braganza; the assembly also declared that Portugal was no longer a dependency of Leon. Alphonso wrested from the Moors Santarem in 1146, and Lisbon in 1147. Some years later he became involved in a war that had broken out among the kings of Spain; and in 1167 he was made prisoner by the soldiers of the king of Leon, and was obliged to surrender as his ransom almost all the conquests he had made in Galicia. In 1184, in spite of his great age, he had still sufficient energy to relieve his son, Sancho, who was besieged in Santarem by the Moors. He died shortly after, in 1185. Alphonso was a man of gigantic stature, being, according to some authors, 7ft. high. He is revered as a saint by the Portuguese, both on account of his personal character and as the founder of their kingdom.

ALPHONSO II., "the Fat" (1185-1223), succeeded his father, Sancho I. in 1211. He gained a victory over the Moors at Alcácer do Sal in 1217. He was excommunicated by Honorius III. for trying to seize part of the Church revenues for public purposes.

ALPHONSO III. (1210-1279), son of Alphonso II., succeeded his brother, Sancho II., in 1248. Besides making war upon the Moors, he was, like his father, frequently embroiled with the Church. In his reign Algarve became part of Portugal.

ALPHONSO IV. (1290-1357) succeeded his father, Dionis, whose death he had hastened by his intrigues and rebellions, in 1325. Alphonso connived at the barbarous murder of Iñez de Castro, who had secretly married his son, Peter. In revenge Peter devastated the whole of the country between the Douro and the Minho before he was reconciled to his father.

ALPHONSO V., "Africano" (1432-1481) succeeded his father, Edward, in 1438. During his minority he was placed under the regency, first of his mother, and latterly of his uncle, Dom Pedro. In 1448 he assumed the government and married Isabella, Dom Pedro's daughter. Next year, being led by what he afterwards discovered to be false representations, he declared Dom Pedro a rebel and defeated his army in a battle at Alfarrobeira, in which his uncle was slain. In 1458, and with more numerous forces in 1471, he invaded the territories of the Moors in Africa and by his successes there acquired his surname of "the African." On his

return to Portugal in 1475 he invaded Castile, where two princesses were disputing his succession to the throne. Alphonso was betrothed to the princess Juana, and was proclaimed king of Castile and Leon; but in 1476 he was defeated at Toro by Ferdinand, the husband of Isabella of Castile. He sought in vain the assistance of Louis XI., and was compelled to abdicate in favour of his son John. John refused the crown, and Alphonso ruled for two years longer. He then retired into a monastery at Cintra.

ALPHONSO VI. (1643-1675), the second king of the house of Braganza, succeeded his father in 1656. In 1667 he was compelled by his wife and brother to abdicate, and was banished to the island of Terceira. These acts, which the vices of Alphonso had rendered necessary, were sanctioned by the Cortes in 1668.

ALPHONSO I. (739-757), the first of the Kings of Spain, is said to have married Ormesinda, daughter of Pelayo, who was raised on the shield in Asturias as king of the Goths after the Arab conquest. He is also said to have been the son of Peter, duke of Cantabria. It is not improbable that he was, in fact, an hereditary chief of the Basques, but no contemporary records exist. His title of "the Catholic" itself may very well have been the invention of later chronicles.

ALPHONSO II. (789-842), his reputed grandson, bears the name of "the Chaste." The Arab writers who speak of the Spanish kings of the north-west as the Beni-Alfons, appear to recognize them as a royal stock derived from Alphonso I. The events of his reign are in reality unknown. Poets of a later generation invented the story of the secret marriage of his sister Ximena with Sancho, count of Saldaña, and the feats of their son, Bernardo del Carpio. Bernardo is the hero of a *cantar de gesta* (*chanson de geste*) written to please the anarchical spirit of the nobles.

The first faint glimmerings of mediaeval Spanish history begin with ALPHONSO III. (866-914) surnamed "the Great." Of him also nothing is really known except the bare facts of his reign, and of his comparative success in consolidating the kingdom known as "of Galicia," or "of Oviedo," during the weakness of the Omayyad princes of Cordova. ALPHONSO IV. (924-931) has a faint personality. He resigned the crown to his brother, Ramiro, and went into a religious house. A certain instability of character is revealed by the fact that he took up arms against Ramiro, having repented of his renunciation of the world. He was defeated, blinded, and sent back to die in the cloister of Sahagun. It fell to ALPHONSO V. (999-1028) to begin the work of reorganizing the Christian kingdom of the north-west after a most disastrous period of civil war and Arab inroads. Enough is known of him to justify the belief that he had some of the qualities of a soldier and a statesman. His name, and that of his wife Geloria (Elvira), are associated with the grant of the first franchises of Leon. He was killed by an arrow while besieging the town of Viseu in northern Portugal, then held by the Mohammedans. (For all these kings see SPAIN: History.)

With ALPHONSO VI. (1065-1109) we come to a sovereign of strong personal character. Much romance has gathered round his name. In the *cantar de gesta* of the Cid he plays the part attributed by mediaeval poets to the greatest kings, to Charlemagne himself. He is alternately the oppressor and the victim of heroic and self-willed nobles—the idealized types of the patrons for whom the jongleurs and troubadours sang. (For the events of his reign see the article SPAIN: History.) He is the hero of a *cantar de gesta* which, like all but a very few of the early Spanish songs, e.g., the *cantar* of Bernardo del Carpio, and the *Infantes* of Lara, exists now only in the fragments incorporated in the chronicle of Alphonso the Wise, or in ballad form. His flight from the monastery of Sahagun, where his brother Sancho endeavoured to imprison him, his chivalrous friendship for his host Almamun of Toledo, *caballero aunque mon*, a gentleman although a Moor, the passionate loyalty of his vassal, Peranzules, and his brotherly love for his sister, Urraca of Zamora, may owe something to the poet who took him for hero. They are the answer to the poet of the nobles who represented the king as having submitted to take a degrading oath at the hands of Ruy Diaz of Bivar (the Cid), in the church of Santa Gadea at Burgos, and as having then persecuted the brave man who defied him. When every allowance is made, Alphonso VI. stands out as a strong man fighting for his own hand, which in his

case was the hand of the king whose interest was law and order, and who was the leader of the nation in the reconquest. On the Arabs he impressed himself as an enemy very fierce and astute, but as a keeper of his word. A story of Mohammedan origin, which is probably no more historical than the oath of Santa Gadea, tells of how he allowed himself to be tricked by Ibn Ammar, the favourite of Al Motamid, the king of Seville. They played chess for an extremely beautiful table and set of men, belonging to Ibn Ammar. Table and men were to go to the king if he won. If Ibn Ammar gained he was to name the stake. The latter did win and demanded that the Christian king should spare Seville. Alphonso kept his word. Whatever truth may lie behind the romantic tales of Christian and Mohammedan, we know that Alphonso represented in a remarkable way the two great influences then shaping the character and civilization of Spain. At the instigation, it is said, of his second wife, Constance of Burgundy, he brought the Cistercians into Spain, established them in Sahagun, chose a French Cistercian, Bernard, as the first archbishop of Toledo after the reconquest in 1085, married his daughters, legitimate and illegitimate, to French princes, and in every way forwarded the spread of French influence—then the greatest civilizing force in Europe. He also drew Spain nearer to the papacy, and it was his decision which established the Roman ritual in place of the old missal of Saint Isidore—the so-called Mozarabic. On the other hand he was very open to Arabic influence. He protected the Mohammedans among his subjects and struck coins with inscriptions in Arabic letters. After the death of Constance he perhaps married, and he certainly lived with Zaida, said to have been a daughter of "Benabet" (Al Motamid), Mohammedan king of Seville. Zaida, who became a Christian under the name of Maria or Isabel, bore him the only son among his many children, Sancho, whom Alphonso designed to be his successor, but who was slain at the battle of Uclés in 1108. Women play a great part in Alphonso's life.

ALPHONSO VII., "the Emperor" (1126-1157), is a dignified and somewhat enigmatical figure. A vague tradition had always assigned the title of emperor to the sovereign who held Leon as the most direct representative of the Visigoth kings, who were themselves the representatives of the Roman empire. But though given in charters, and claimed by Alphonso VI. and the Battler, the title had been little more than a flourish of rhetoric. Alphonso VII. was crowned emperor in 1135, after the death of the Battler. The weakness of Aragon enabled him to make his superiority effective. He appears to have striven for the formation of a national unity, which Spain had never possessed since the fall of the Visigoth kingdom. The elements he had to deal with could not be welded together. Alphonso was at once a patron of the Church and a protector if not a favourer of the Mohammedans, who formed a large part of his subjects. His reign ended in an unsuccessful campaign against the rising power of the Almohades. Though he was not actually defeated, his death in the Pass of Muradel in the Sierra Morena, while on his way back to Toledo, occurred in circumstances which showed that no man could be what he claimed to be—"king of the men of the two religions." His personal character does not stand out with the emphasis of those of Alphonso VI. or the Battler. Yet he was a great king, the type and, to some extent, the victim of the confusions of his age—Christian in creed and ambition, but more than half oriental in his household.

ALPHONSO VIII. (1158-1214), king of Castile only, and grandson of Alphonso VII., is a great name in Spanish history, for he led the coalition of Christian princes and foreign crusaders which broke the power of the Almohades at the battle of the Navas de Tolosa in 1212. The events of his reign are dealt with under SPAIN. His personal history is that of many mediaeval kings. He succeeded to the throne on the death of his father, Sancho, at the age of a year and a half. Though proclaimed king, he was regarded as a mere name by the unruly nobles to whom a minority was convenient. The devotion of a squire of his household, who carried him on the pommel of his saddle to the stronghold of San Esteban de Gormaz, saved him from falling into the hands of the contending factions of Castro and Lara, or of his uncle, Ferdinand of Leon, who claimed the regency. The loyalty of the town of Avila pro-

tected his youth. He was barely 15 when he came forth to do a man's work by restoring his kingdom to order. It was only by a surprise that he recovered his capital, Toledo, from the hands of the Laras. His marriage with Leonora of Aquitaine, daughter of Henry II. of England, brought him under the influence of the greatest governing intellect of his time. Alphonso VIII. was the founder of the first Spanish university, the *studium generale* of Palencia, which, however, did not survive him.

ALPHONSO IX. (1188-1230) of Leon, first cousin of Alphonso VIII. of Castile, and numbered next to him as being a junior member of the family (see the article SPAIN for the division of the kingdom and the relationship), is said by Ibn Khaldun to have been called the "Baboso" or Slobberer, because he was subject to fits of rage, during which he foamed at the mouth. Though he took a part in the work of the reconquest, this king is chiefly remembered by the difficulties into which his successive marriages led him with the pope. He was first married to his cousin, Teresa of Portugal who bore him two daughters and a son who died young. The marriage was declared null by the pope, to whom Alphonso paid no attention till he was presumably tired of his wife. It cannot have been his conscience which constrained him to leave Teresa, for his next step was to marry Berengaria of Castile, who was his second cousin. For this act of contumacy the king and kingdom were placed under interdict. The pope was, however, compelled to modify his measures by the threat that if the people could not obtain the services of religion they would not support the clergy, and that heresy would spread. The king was left under interdict personally, but to that he showed himself indifferent, and he had the support of his clergy. Berengaria left him after the birth of five children, and the king then returned to Teresa, to whose daughters he left his kingdom by will.

ALPHONSO X., *El Sabio*, or "the Learned" (1252-1284), is perhaps the most interesting, though he was far from being the most capable, of the Spanish kings of the middle ages. (His merits as a writer are dealt with in the article SPAIN: *Literature*.) His scientific fame is based mainly on his encouragement of astronomy. As a ruler he showed legislative capacity, and a very commendable wish to provide his kingdoms with a code of laws and a consistent judicial system. The *Fuero Real* was undoubtedly his work, and he began the code called the *Siete Partidas*, which, however, was only promulgated by his great-grandson. His descent from the Hohenstaufen, through his mother, a daughter of the emperor Philip, gave him claims to represent the Suabian line. The choice of the German electors, after the death of Conrad IV. in 1254, misled him into wild schemes which never took effect, but caused immense expense. To obtain money he debased the coinage, and then endeavoured to prevent a rise in prices by an arbitrary tariff. The little trade of his dominions was ruined, and the burghers and peasants were deeply offended. His nobles, whom he tried to cow by sporadic acts of violence, rebelled against him. His second son, Sancho, enforced his claim to be heir, in preference to the children of Ferdinand de la Cerda, the elder brother, who died in Alphonso's life. Son and nobles alike supported the Moors, when he tried to unite the nation in a crusade; and when he allied himself with the rulers of Morocco they denounced him as an enemy of the faith. A reaction in his favour was beginning in his later days, but he died defeated and deserted at Seville, leaving a will by which he endeavoured to exclude Sancho.

ALPHONSO XI. (1312-1350) is variously known among Spanish kings as the Avenger or the Implacable, and as "he of the Rio Salado." The first two names he earned by the ferocity with which he repressed the disorder of the nobles after a long minority; the third, by his victory over the last formidable African invasion of Spain in 1340. The chronicler who records his death prays that "God may be merciful to him, for he was a very great king." The mercy was needed. Alphonso XI. never went to the insane lengths of his son, Peter the Cruel, but he could be abundantly sultanesque in his methods. He killed for reasons of state, without form of trial, while his open neglect of his wife, Maria of Portugal, and his ostentatious passion for Leonora de Guzman, who bore him a large family of sons, set Peter an example which he did not fail to better. It may be that his early death, during the great

plague of 1350, at the siege of Gibraltar, only averted a desperate struggle with his legitimate son, though it was a misfortune in that it removed a ruler of eminent capacity, who understood his subjects well enough not to go too far.

BIBLIOGRAPHY.—The lives of all the early kings of Spain will be found in the general histories (see the article SPAIN: *Bibliography*), of which the most trustworthy is the *Anales de la Corona de Aragon*, by Geronimo Zurita (Saragossa, 1610). See also the *Chronicles of the Kings of Castile* in the *Biblioteca de Autores Españoles de Riva denevra* (1846-80, vols. lxvi., lxviii., lxx.). (D. H.)

ALPHONSO XII. (1857-1885), first of the Kings of ALL SPAIN, became king of Spain, son of Isabella II. and Maria Fernando Francisco de Assisi, eldest son of the duke of Cadiz, was born on Nov. 28, 1857. When Queen Isabella and her husband were forced to leave Spain by the revolution of 1868, he accompanied them to Paris, and from thence he was sent to the Theresianum at Vienna to continue his studies. On June 25, 1870, he was recalled to Paris, where his mother abdicated in his favour, in the presence of a number of Spanish nobles who had followed the fortunes of the exiled queen. He assumed the title of Alphonso XII.; for although no king of united Spain had previously borne the name, the Spanish monarchy was regarded as continuous with the more ancient monarchy, represented by the 11 kings of Leon and Castile already referred to. Shortly afterwards he proceeded to Sandhurst to continue his military studies, and while there he issued, on Dec. 1, 1874, in reply to a birthday greeting from his followers, a manifesto proclaiming himself the sole representative of the Spanish monarchy. At the end of the year, when Marshal Serrano left Madrid to take command of the northern army, General Martinez Campos entered Valencia in the king's name. Thereupon the president of the council resigned, and the power was transferred to the king's plenipotentiary and adviser, Canovas del Castillo. In 1876 a vigorous campaign against the Carlists, in which the young king took part, resulted in the defeat of Don Carlos and his abandonment of the struggle. Early in 1878 Alphonso married his cousin, Princess Maria de las Mercedes, daughter of the duc de Montpensier, but she died within six months of her marriage. Towards the end of the same year a young workman of Tarragona, Oliva Marcousi, fired at the king in Madrid. On Nov. 29, 1879, he married Maria Christina, daughter of the archduke Charles Ferdinand. During the honeymoon a pastrycook named Otero fired at the young sovereigns as they were driving in Madrid. The children of this marriage were Maria de las Mercedes, titular queen from the death of her father until the birth of her brother, born on Sept. 11, 1880, married on Feb. 14, 1901, to Prince Carlos of Bourbon, died on Oct. 17, 1904; Maria Teresa, born on Nov. 12, 1882, married to Prince Ferdinand of Bavaria on Jan. 12, 1906; and Alphonso. In 1881 the king refused to sanction the law by which the ministers were to remain in office for a fixed term of 18 months, and upon the consequent resignation of Canovas del Castillo, he summoned Sagasta, the Liberal leader, to form a cabinet. Alphonso died of phthisis on Nov. 24, 1885. Coming to the throne at such an early age, he had served no apprenticeship in the art of ruling, but he possessed great natural tact and a sound judgment ripened by the trials of exile. In his short reign peace was established both at home and abroad, the finances were well regulated, and the various administrative services were placed on a basis that afterwards enabled Spain to pass through the disastrous war with the United States without even the threat of a revolution.

ALPHONSO XIII. (1886-), king of Spain, was born in Madrid, May 17 1886, the posthumous son of Alphonso XII. Belonging to the House of Bourbon-Habsburg, he was baptized as Leon Fernando Maria Jaime Isidoro Pascual Antonio. Born a king, he was proclaimed at birth sovereign under the regency of his mother. Great care was taken to remedy the delicacy of his physique, with the result that in his 16th year he was hale and vigorous. His education was not neglected. He mastered thoroughly English, French and German and acquired a fair knowledge of history and the elements of agriculture.

On coming of age in 1902 Alphonso XIII. endeavoured to get into touch with his subjects in various provinces of his realm, entered into personal relations with the representatives of science,

art, and labour and sought everywhere to awaken enterprise and encourage effort. In 1905 he visited Austria, Germany, England and France. One day while driving in Paris, with the president of the French republic, he narrowly escaped death from the bomb of an unknown criminal.

On May 31 1906, Alphonso married Victoria Eugénie, daughter of Princess Henry of Battenberg, and granddaughter of Queen Victoria. On the same day a bomb was thrown at their carriage by Mateo Morral, but happily neither of the sovereigns was injured. After the birth of his eldest son Alphonso (May 10 1907), who was proclaimed prince of the Asturias, the king renewed his travels in Spain, France and England, and at the close of the undecided African campaign of 1909 visited Melilla, where he familiarized himself with the scenes of the fighting. At the funeral of his murdered premier, Canalejas, Alphonso XIII. fearlessly followed the coffin on foot amid a great concourse of people. In April 1913, when returning from the ceremony of the oath to the national flag in Madrid, the king was fired at three times and again he escaped unhurt. His coolness and dignified behaviour on this occasion won for him enthusiastic ovations, and the generosity that prompted him to commute the death sentence on his would-be assassin intensified his popularity.

In the early days Alphonso had been singled out as the innocent symbol of an odious régime, but later he was charged with being the fomentor of a shameful system of favouritism. The Melilla campaign brought home the evils of bad government alike to the listless masses, who furnished the blood and money to carry it on, and to the officers' corps, who complained that rewards and promotion were lavished on drones while those who bore the brunt of the struggle were systematically ignored; and the monarch's popularity began to decline. By way of lessening the dissatisfaction the king, after a visit to President Poincaré, announced Spain's adherence to the Franco-Anglo-Russian entente respecting Morocco (1913) and in the same year he strove to settle the Catalan difficulty by adopting decentralization and bestowing a large measure of autonomy on various provinces for administrative purposes. But the Morocco problem seemed perennial and the concession of home rule failed to satisfy the extremists in Catalonia, who forthwith clamoured for a degree of political independence incompatible with Spanish unity and destructive of their own economic prosperity.

Then it was that Antonio Maura (q.v.), having outgrown parties and factions, emerged as one of the few genuine statesmen produced by Spain in modern times. His measures of reform were root-reaching, but he was thwarted by the machinations of his adversaries, the perfidy of his partisans, and his own lack of peremptory energy, and was therefore unable to enforce the restraints prescribed by the Constitution. With the failure of Maura's experiment the last flicker of hope for Spain seemed extinguished. The position of the king became increasingly difficult, notwithstanding his efforts to better it. At the outbreak of the Portuguese revolution his official attitude, despite his dream of an Iberian union and the temptation to realize it, was irreproachable, and during the World War, when Spain's position was superlatively difficult, the king remained scrupulously neutral and rendered immense services to the cause of humanity.

At home, he was less fortunate. The war, by depriving the Rif tribes of arms and ammunitions, had placed them at the mercy of Spain, but the parliamentarians allowed the opportunity to slip and the Moors bled the nation white (*see* articles, MOROCCO and SPAIN). The monarch was held partly responsible for this disaster and also for the serious abuses prevalent throughout the army and the Government. Education was almost non-existent; the army was inefficient; the navy a fiction; justice itself was a sham and a snare, and the nation was but a shuttlecock in the hands of two parties tossed between hopeless ineptitude and insatiable greed. Discerning no prospect of redress, the officers' corps, which was the only organ of remedial action in the peninsula, drafted a reform programme and through the intermediary of the Infantry Union summoned the Government in June 1917 to accept it without restriction or delay. The arrest of its spokesmen only served to reveal the solidarity of the army while the

impotence of the cabinet and the triumph of the officers dealt a blow to parliamentary government from which it has not since recovered. But before its final collapse the rulers allowed a tidal wave of syndicalist terrorism to invade Catalonia and render normal existence impossible there.

At this conjuncture Gen. Primo de Rivera (q.v.), aided by a group of resolute comrades and trusting in the king's official acquiescence in an accomplished fact, seized the reins of power, dismissed the cabinet, proclaimed the directorate, suspended the Constitution, introduced censorship, and suppressed for the time syndicalism, separatism, and wholesale assassination. After two years' tenure of office he lost the support of some of his partisans and aroused the active hostility of many passive adversaries, while conspiracies were hatched in Paris, Barcelona and Madrid, some for the purpose of assassinating the king, in June 1925, others with the object of overturning the directorate in Nov. 1925. In Sept. 1927 the king authorized Primo de Rivera to convene a consultative national assembly consisting mainly of supporters of the dictator, for the purpose of drawing up a definitive Constitution. It was announced that in the year 1930 a "real parliament" would be convoked which would accept this Constitution with suitable modifications, and that Spain would return to normal political life. The dictator emphasized the fact that the assembly of 1927 made no claim to be a parliament and added that the restrictions with which it was hedged round were imposed for the purpose of keeping the members to their main task, the drafting of the new Constitution. (E. J. D.)

ALPHONSUS A SANCTA MARIA, or ALPHONSO DE CARTAGENA (1396-1456), a Spanish historian, was born at Carthage, succeeded his father, Paulus, as bishop of Burgos, and was sent by John II. of Castile to the Council of Basle in 1431.

His principal work is *Rerum Hispanorum Romanorum imperatorum, summorum pontificum, nec non regum Francorum anacephaleosis*, a history of Spain from the earliest times down to 1456; it was printed at Granada in 1545, and also in the *Rerum Hispanicarum Scriptores aliquot*, by R. Bel (Frankfort, 1579). Alphonsus died on July 12, 1456.

ALPINI, PROSPERO, or PROSPER ALPINUS (1553-1617), Italian physician and botanist, was born at Marostica, in the republic of Venice. He studied medicine at Padua, and practised as a physician. During a three years' residence in Egypt as physician to the Italian consul in Cairo he studied the palm-tree, and he seems to have deduced the doctrine of the sexual difference of plants, which was adopted as the foundation of the Linnaean system. He says that "the female date-trees or palms do not bear fruit unless the branches of the male and female plants are mixed together; or, as is generally done, unless the dust found in the male sheath or male flowers is sprinkled over the female flowers." In 1593 he was appointed professor of botany at Padua. He was succeeded in the botanical chair by his son Alpino Alpini (d. 1637). His best-known work is *De Plantis Aegypti liber* (Venice, 1592). His *De Medicina Egyptiorum* (Venice, 1591) is said to contain the first account of the coffee plant published in Europe.

ALPS, the collective name for one of the great mountain systems of Europe stretching from the Gulf of Genoa to Vienna, and rising between the plains of northern Italy and of southern Germany. The Alps do not present so continuous a barrier as the Himalayas, the Andes or even the Pyrenees. They are less extensive than the Urals or the Scandinavian highlands. They are formed of numerous ranges, divided by comparatively deep valleys. This mountain mass forms a broad band, convex towards the north, while most of the valleys lie between the directions west to east and south-west to north-east. Many deep transverse valleys intersect the prevailing direction of the ridges and facilitate the passage of man, animals and plants, as well as of currents of air which mitigate the contrast that would otherwise be found between the climates of the opposite slopes. The derivation of the name Alps is uncertain; in all parts of the great chain itself the term *Alp* (or *Alm* in the Eastern Alps) is strictly applied to the high mountain pastures (*see* ALP), and not to the peaks and ridges of the chain.

Limits of the Alps.—If we merely desire to distinguish the Alps from minor ranges the best limits are on the west (strictly speaking, south), the Col d'Altare or di Cadibona (1,624ft.), leading from Turin to Savona and Genoa, and on the east the line of the railway over the Semmering Pass (3,215ft.) from Vienna to Marburg in the Mur valley, and on by Laibach to Trieste. An Italian commission in 1926 placed the limit on the east at a line from Vienna through Graz to Fiume. But if we confine the term to those parts where the height is sufficient to support perpetual snow, the limit to the west will be the Col di Tenda (6,145ft.), leading from Cuneo (*Coni*) to Ventimiglia, while on the east our line will be the route over the Radstädter Tauern (5,702ft.) and the Katschberg (5,384ft.) from Salzburg to Villach in Carinthia, and thence by Klagenfurt to Marburg and so past Laibach in Carniola on to Trieste.

On the north side, the Alps (in either sense) are definitely bounded by the Rhine from Basle to the Lake of Constance, the plain of Bavaria and the low foot-hills from Salzburg to the neighbourhood of Vienna. The waters of the northern slope of the Alps find their way either into the North sea through the Rhine, or into the Black sea by means of the Danube, not a drop reaching the Baltic sea. On the south side the mountains from near Turin to near Trieste subside into the great plain of Piedmont, Lombardy and Venetia. The true west section of the Alps runs, from near Turin to the Col di Tenda, in a southerly direction, then bends east to the Col d'Altare, which divides it from the Apennines.

Divisions.—The Alps consist of a main chain, with ramifications, and of several minor chains. They form a single connected whole as contrasted with the plains at their base, the only breaks in them being mountain passes at high altitudes. For the sake of convenience the best marked passes have long been used to serve as limits within the chain, whether to distinguish several great divisions or to break up these into smaller ones. W. A. B. Coolidge's system considers only its topographical aspect. The divisions given lie between the Col di Tenda and the route over the Radstädter Tauern. Three main divisions are generally distinguished: the Western Alps, extending from the Col di Tenda to the Simplon Pass; the Central Alps from the Simplon Pass to the Reschen Scheideck Pass, and the Eastern Alps from the latter to the Radstädter Tauern route, with a bend outwards towards the south-east in order to include the higher summits of the South-Eastern Alps. Assuming these divisions, it is found convenient to subdivide the whole mountain system into 18 smaller groups—5 in the Western Alps, 7 in the Central Alps and 6 in the Eastern Alps. These, with the limits of each subdivision, are as follow:—

Western Alps.—The Maritime Alps (from the Col di Tenda to the Col de l'Argentière). The Cottian Alps (from the Col de l'Argentière to the Mont Cenis Pass and west to the Col du Galibier). The Dauphiné Alps (from the Col du Galibier, westwards and southwards). The Graian Alps (from the Mont Cenis to the Little St. Bernard Pass). These are usually divided into three groups, the Central (the watershed between the two passes named), the Western or French, and the Eastern or Italian. The Pennine Alps (from the Little St. Bernard to the Simplon Pass).

Central Alps.—The Bernese Alps (from Lake Geneva to the Furka Pass, the Reuss valley and Lake Lucerne). The Lepontine Alps (from the Simplon to the Splügen and south to the Furka and the Oberalp Passes). The eastern portion of this range is sometimes named the Adula Alps (from the St. Gotthard to the Splügen Pass). The Tödi Range (from the Oberalp to the Klausen Pass). The Glarus Alps (north of the Klausen Pass). The Bernina Alps (from the Maloja to the Reschen Scheideck and the Stelvio, south and east of the Val Bregalia and of the Engadine and north of the Valtellina). The Albula Range (from the Splügen to the Fluela Pass, north and west of the Val Bregalia and of the Engadine). The Silvretta and Rhätikon Ranges (from the Fluela to the Reschen Scheideck and the Arlberg Pass).

Eastern Alps.—The Alps of Bavaria. Vorarlberg and Salzburg (north of the Arlberg Pass, Innsbruck, the Pinzgau and the Enns valley). The Central Tirol Alps (from the Brenner to the Radstädter Tauern Pass, north of the Drave valley and south

of the Pinzgau and the Enns valley). This includes the Zillertal and the Tauern ranges. The Ortler, Stubai and Oetzthal ranges (from the Reschen Scheideck and the Stelvio to the Brenner Pass, south of the Inn valley, and north of the Tonale Pass). The Lombard Alps (from Lake Como to the Adige valley, south of the Valtellina and the Aprica and the Tonale Passes). This division includes the Adamello, Presanella, Brenta and Bergamasque ranges. The Dolomites of south Tirol (from the Brenner to the Monte Croce Pass, and south of the Pusterthal). The South-Eastern Alps (east of the Monte Croce Pass). This division includes the Julian, Carnic and the Karawanken Alps.

In 1926 an Italian commission considered the subdivision of the Alps and their suggestions embodied several modifications of the above. (See Douglas W. Freshfield, *Geog. Journ.* Jan. 1928, p. 37.)

Geology and Structure.—The Alps form but a small portion of a great zone of crumpling which stretches in a series of curves from the Rif mountains of Morocco to beyond the Himalayas. The whole group of mountains may be conveniently called the Alpine-Himalayan group. Within this zone the crust of the earth has been ridged up into a complex series of creases and folds, out of which the great mountain chains of southern Europe and Asia have been carved by atmospheric and other agencies. Superficially, the continuity of the zone is broken at intervals by gaps of greater or less extent; these are due in part at least to the subsidence of portions of the folded belt and their subsequent burial by more recent accumulations. Such a gap is that between the Alps and the Carpathians.

This mountain system, which stretches a quarter of the way across the globe, is formed not of a single fold of the crust but of a number of such, often parallel to one another and to the general direction (trend) of the chain. The mountains of southern Europe are an exception to the last statement, for we find that five great mountain systems radiate from the Alps themselves. One arm stretches east through the Carpathians and another to the south-east through the Dinaric Alps. The latter passes through Candia and Rhodes into the Taurus mountains, where it is joined by the continuation of the Carpathian branch, and east into the Iran Plateau and the Himalayas. This arm appears to cross southern China whilst there is a loop to the south forming the Burmese-Malayan arc. The third arm stretches west from the mountains of Provence into the Pyrénées and the northern Spanish highlands; a fourth through Liguria, Corsica, Elba, the Apennines, Sicily, the Balearic Islands, the Baetic Cordillera, across the Strait of Gibraltar and into the Rif mountains of Morocco. This latter demarcation of the fourth arm is according to Staub, but Kober considers the Baetic Cordillera as part of the Provence-Pyrenees branch, and thinks that the Apennines branch continues by way of Sicily directly into the Rif mountains. A fifth narrow chain stretches from Grenoble into the Jura mountains. These several chains, forming one great mountain system, were uplifted during the same period of earth-movement and by the same set of causes. Each branch is in a certain sense a separate unit but each is represented in the Alps which is the narrowest portion of the whole mountain belt, and in consequence every aspect of the geology of the Alps is of paramount importance when the whole chain is considered.

Sedimentary rocks form a large part of the Alps. These range from the Trias to the Miocene, but older rocks (Permian, Carboniferous, Devonian, Silurian and possibly Cambrian) also occur and are of considerable importance, especially in the Eastern Alps. Crystalline gneisses and schists and igneous rocks also occur. There are many rock types of local importance which need special mention. Here we find the characteristic Tertiary rocks, Molasse, Nagelfluh and Flysch. The former consists of a remarkably uniform series which crops out along the northern border of the Alps in the Great Swiss plateau. To the south of this is the Flysch zone which attains more important dimensions in the east than in the west. Other types which have commanded universal interest are the Gosau beds, Verrucano and Schistes Lustrés. An intensive study of the geology and structure of the Alps has been carried out during the last decade.

The Alps stand upon the site of a geosyncline which, from late Carboniferous times, through the whole of the Mesozoic period until the Miocene period, existed between the Eurasian (Foreland) landmass to the north and the African (Hinterland) landmass to the south. The sea which occupied this depression has been called by Suess and others the "Tethys." Great thicknesses of deposits were laid down in it, causing the floor to sink and thus enabling the sediments to be deposited at approximately the same depth below the sea level. Termier compared this geosyncline to a huge vice, the jaws of which moved slowly inwards concurrently as deposition was taking place between them. The Hinterland moved northward toward the Foreland. Argand has suggested that, by this movement two geanticlines (arches) arose within the geosyncline, thus bringing about the following subdivision:—the Valais Geosyncline (north), the Briançonnais Geanticline, the Piedmont Geosyncline, the Dolin Geanticline and the Canavese Geosyncline. The two geanticlines continued to increase in size as compression proceeded during the whole of the Mesozoic period until the culmination of the movement in the Miocene. The compression was so great that the geanticlines rose completely out of the Tethys and were driven northward on to the Foreland in the form of huge recumbent folds, to which the name of "Nappes" is given. The geanticlines can now be identified in the Pennine Alps as the Great St. Bernard Nappe and the Dent Blanche Nappe. Further, the rise of these two structures also brought about the formation of other structures within the Alpine geosynclines; the Great St. Bernard Nappe forcing upward and forward the three Simplon Nappes which lie beneath it, and the Dent Blanche Nappe similarly bringing into being the Monte Rosa Nappe. There are thus in the Pennine Alps six major tectonic elements which arose from the Alpine geosyncline.

Apart from these, the Foreland and the Hinterland both played important rôles and large tracts of the mountains belong to these divisions. Sedimentary rocks were laid down in epicontinental seas upon the peneplained Hercynian surfaces of these continental masses and these rocks, as well as the fundamental crystalline rocks, were affected by the Alpine earth-movements. The northward movement of the Hinterland was so great that portions of it were driven completely over the geosynclinal rocks on to the Foreland itself. Sedimentary rocks of the same age belong to the Foreland, the Hinterland and the Geosyncline, but there are distinct differences in facies between them as well as differences within each group. Recumbent folding and overthrusting are common throughout the whole of the Alps, but the particular type of structure found in any locality depends upon the nature of the rocks and their location in one or other of the main divisions.

From a geological point of view it is convenient to divide the Alps into Western Alps and Eastern Alps along the Rhine-line (a north-south line through the Lake of Constance, Coire and the Septimer Pass). The following is a summary of the chief tectonic divisions:—

Western Alps.—(a) The Jura mountains; (b) the great Swiss plateau of Tertiary rocks; (c) the Prealps, with exotic Palaeozoic, Mesozoic and Tertiary rocks; (d) the zone of the high Calcareous Alps of Switzerland (the Helvetic zone of Staub); (e) the "zone of Mont Blanc" in which are the crystalline Hercynian massifs, Mercantour, Pelvoux and Belledonne, Mont Blanc and Aiguilles Rouges, Gotthard, Aar and Gastern-Erstfeld (the Autochthonous massifs of Heim); (f) the Pennine zone, in which occur the Pennine Nappes (Pennides of Staub); (g) the zone of the "Inner Roots," containing the "roots" of the Pennine, Austride and Dinaride Nappes.

Eastern Alps.—(a) The great Swiss plateau with Tertiary rocks; (b) the northern Flysch zone (the East Alpine equivalent of the zone of the high Calcareous Alps); (c) the zone of the Eastern Alps; (1) the northern Limestone zone of Triassic, Jurassic and Cretaceous rocks; (2) the Greywacke zone of schists and limestones of Palaeozoic age; (3) the central zone, forming the chief mountain tracts of the Eastern Alps and built up chiefly of Austride Nappes; (4) the Pennine "windows" which occur within the central zone and in which Pennine Nappes are found; (d) the Dinaride zone in which the Dinaride Nappes occur and which is

formed of Palaeozoic and Mesozoic rocks and several plutonic intrusions.

Of these divisions the Jura mountains, the great Swiss plateau, the zone of the high Calcareous Alps, the northern Flysch zone and the "zone of Mont Blanc" belong to the Foreland; the Pennine zone, the Pennine "windows" and part of the zone of the "Inner Roots" belong to the Alpine geosyncline, whilst the northern Limestone zone, the Greywacke zone, the central zone, the Prealps, part of the zone of the "Inner Roots" and the Dinaride zone belong to the Hinterland.

Although the Foreland acted as a single unit during the Alpine earth-movements it did not possess a simple homogeneous structure.

Some portions of it (e.g., the central plateau of France, the Vosges, the Black Forest, the Bohemian mountains and the massifs of the "zone of Mont Blanc") resisted the northward advance of the folds, and the effect of this is well seen in the trend of the chain. To assist in forming a clear idea of this, a simple illustration will suffice.

DIAGRAM ILLUSTRATING FORMATION OF THE ALPS
If two books, A and B, are placed on a cloth-covered table, and pressure is exercised on the cloth in direction of the arrow, folds resembling in miniature the "nappes" of the Alps will be produced

Upon a table covered by a thick cloth lay two books (A and B) in the positions shown in the figure. If the two hands are placed flat upon the table and the cloth pushed in the direction indicated, it will at once be rucked up into a fold which will follow a curve not unlike that of the Alps. The precise form and character of the folds will depend upon the nature

of the cloth, position and number of obstructions, and other accidental circumstances. Moreover, if sufficient pressure be exerted, the folds will lie one above the other as in the Alps themselves. Here also there were two sets of obstructions, an outer group comprising the Maures-Esterel massif, central plateau of France, Vosges-Black Forest and Bohemian massifs; and an inner group, the "zone of Mont Blanc." The outer group, well within the Foreland, determined the trend of the chains of the Basses and Dauphiné Alps, the Jura mountains and Swabian Alps. The effect of the "zone of Mont Blanc," nearer the southern edge of the Foreland, is seen in the Pennine and Eastern Alps. Here Staub has identified ten distinct arcs, five in the Eastern Alps and five in the Western Alps. The latter are more distinct than those east of the Rhine-line, for the massifs of the "zone of Mont Blanc" all occur in the Western Alps, but the occurrence of arcs farther east indicates the presence of similar massifs buried beneath the Austrides. The presence of these is further indicated by the occurrence of culminations, which are portions of the true nappe mountains in which the lower elements have been forced to high altitudes, having been driven over elevated portions of the Foreland. Denudation, especially river action, has brought about the removal of much of these upper structures and has revealed different lower units in different districts. Vertical movement, during and since the orogenic period, has made this type of segmentation more marked. Between two culminations a tectonic depression occurs in which, owing to downward sagging, the uppermost tectonic elements have been preserved from denudation. Staub has identified eleven culminations and eleven depressions in the Alps, and in the Western Alps the culminations occur in each case directly behind the individual massifs of the "zone of Mont Blanc."

The massifs of the "zone of Mont Blanc" are, generally speaking, large granitic intrusions (batholiths), surrounded by crystalline schists and gneisses with sedimentary rocks more or less highly metamorphosed. In the Aar, Mont Blanc and Pelvoux massifs "fan" structure has been identified, the granitic rocks being subdivided longitudinally by steep-sided synclines of crystalline schists. The larger massifs of the zone, viz., the Aar-Gotthard, Mont Blanc, Pelvoux and Mercantour, form an inner arc, whilst the smaller ones, viz., the Gastern-Erstfeld, Aiguilles Rouges and Belledonne, form an outer arc. Both arcs are open to the south and adjacent massifs are separated by zones of sedimentary rocks, many of which have been so highly metamorphosed as to be

reduced to paragneisses. The Lötschental zone (paragneisses), the Chamonix sedimentary zone and the zone between the Pelvoux and the Belledonne occur between the two arcs. In the two former zones and in the adjacent massifs the "roots" of the nappes of the high Calcareous Alps are located. The sedimentary cover of the Aiguilles Rouges and the Gastern massifs has been called the Autochthon. This term is also applied by some authorities to all that portion of the sedimentary cover of the Hercynian peneplained surface which has not suffered acute folding, such as is found in the zone of the high Calcareous Alps. Heim further calls the massifs of the "zone of Mont Blanc" the Autochthonous massifs. The Autochthon (in its wider sense) has not suffered acute folding such as is found in the other parts of the Alps, but the rocks are in contact with the surface upon which they were originally deposited.

In the high Calcareous Alps six nappes have been identified. These are called the Helvetides by Staub, but simply the nappes of the high Calcareous Alps by Collet and others. They are named as follows (from the highest to the lowest):—(6) The Oberlaubhorn Nappe, (5) the Mont Bonvin Nappe, (4) the Plaine Morte Nappe, (3) the Wildhorn Nappe, (2) the Diablerets Nappe, (1) the Morcles Nappe.

The Morcles Nappe lies as a great recumbent fold upon the Autochthon, and has its "roots" in the zone of Chamonix. It is composed of sediments ranging from the Trias to the Eocene. Above it lies the Diablerets Nappe, the "roots" of which probably lie in the Mont Blanc massif. This nappe does not possess a reversed limb, this and much of the upper limb having been replaced by a "slide" (Bailey). The Wildhorn Nappe is the greatest of this group and is characterized by a number of digitations in the front of the structure, by disharmonic folding, and a large "involution." Its "roots" probably occur on the south side of the Mont Blanc massif. The three higher nappes (the Ultra-Helvetian Nappes of Heim) crop out in a belt 16m. long on the south side of the Wildhorn-Wildstrubel range, and again on the north side of the high Calcareous Alps in the "zone of Cols," where they form the Internal Prealps. In Eastern Switzerland (*i.e.*, East of the Hasli-Tal) the following units occur:—The Säntis-Drusberg Unit, the Axen Unit, the Glarner-Mürtschen Unit, the Parautochthonous Nappes.

The upper unit (Säntis-Drusberg) is an eastward extension of the Wildhorn Nappe, the Glarner-Mürtschen unit is homologous to the Diablerets Nappe, and the Parautochthonous Nappes rest upon the Autochthon and are homologous to the Morcles Nappe. The Axen unit is not represented in West Switzerland. Three nappes, digitations of one structure, are distinguished in the Säntis-Drusberg unit, four in the Axen unit and two in the Glarner-Mürtschen unit.

With the exception of the Prealps, the great Swiss plateau bounds the high Calcareous Alps on the north. The plateau is underlain by Tertiary rocks, covered by glacial, fluvio-glacial and alluvial deposits. It forms a wide syncline between the Jura mountains and the Western Alps, and in it are gentle flexures, the most important of which is a central anticline which passes from Lake Constance to Lake Geneva. The sedimentary rocks of the Jura mountains are continuous with those of the Autochthon beneath the Tertiary rocks of the great Swiss plateau, but they do not show the same facies. They have been folded into anticlines and synclines, the trend of which is parallel to that of the Alps, but the folds are bunched together in the neighbourhood of the central plateau of France and the Vosges-Black Forest massifs. In the eastern part of the mountains the folding is complicated by block faulting. This portion is known as the Jura tableland whilst the remainder is called the Folded Juras. The folding has only a superficial character, for it dies out downward, the Anhydrite group (Middle Muschelkalk) not being folded. The beds of this latter horizon acted as a plane along which the folding took place, so producing a "décollement." A study of the tectonics of the Jura mountains reveals a remarkable association between them and the Alps.

The Pennine Nappes (Pennides of Staub), being great recumbent folds which arose out of the Alpine geosyncline, consist of

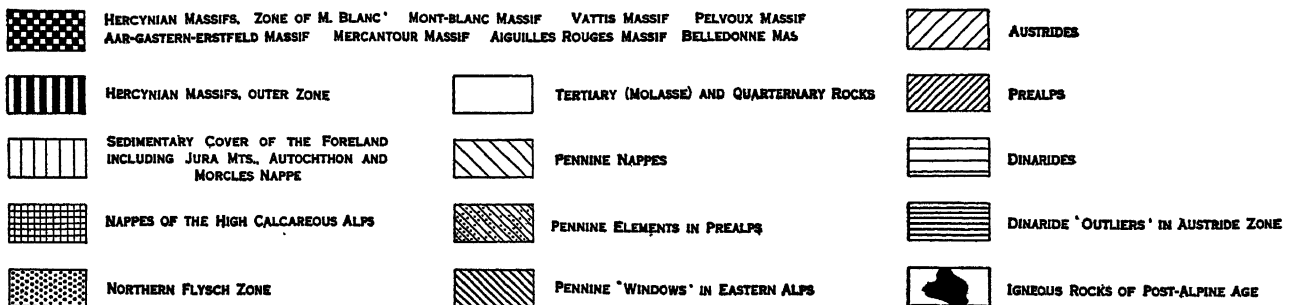

Palaeozoic rocks as crystalline cores, with envelopes of newer sedimentary rocks now highly metamorphosed and known as "schistes lustrés." The evidence for the age of the schistes lustrés is sufficient to prove that they range from the Lower or Middle Trias to the Nummulitic Limestone (Eocene). They occur in the synclinal structures between the crystalline cores of the nappes and also along the frontal archbends of the latter. The three Simplon Nappes, Monte Leone (III.), Lebendun (II.), Antigorio (I.), crop out in the Ticino district, in the Lepontine culmination brought about by the obstacle of the Aar massif. (The figures I., II., etc., after the names of the nappes indicate the relative position of the structures, I. to VI. being Pennine Nappes and VII.-X. Austrides.) The nappes pass round the culmination and are directly connected in the south with their roots. The schistes lustrés associated with them are not so thick as elsewhere in the Pennine Alps. The Great St. Bernard Nappe (IV.), which arose from the Briançonnais geanticline, occurs above the Simplon Nappes, the latter being regarded as major digitations of the higher structure. The Great St. Bernard Nappe is the most extensive of the Pennine units and stretches in an almost unbroken outcrop from the Gulf of Genoa to the Simplon Pass. Schistes lustrés mark the front of it and also separate it from the crystalline core of the Monte Rosa (V.) Nappe, which forms the massifs of Monte Rosa, Grand Paradis, Ambin and Dora Maira and is in fact a major digitation of the highest Pennine Nappe. The Dent Blanche (VI.) Nappe, which arose from the Dolin geanticline, has suffered considerable denudation and its main outcrop in the Dent Blanche-Weisshorn mountain mass is now isolated from the "roots." Here the nappe is in contact with the Great St. Bernard Nappe, for the Monte Rosa Nappe does not reach so far north and the Great St. Bernard has suffered backward folding.

The country east of the Rhine-line belongs principally to the Hinterland. In it we find several tectonic units, named the Austrides by Staub, who also recognizes two divisions in the group, the Upper (Tirolides) and the Lower (Grisonides), both so named because of the location of their main outcrops. This is Staub's scheme, but Kober uses the name East Alpine Nappes for the Austrides and recognizes in them four main divisions. The Austrides overlie the Pennine Nappes in the Eastern Alps, for where denudation has been great the lower structures are exposed beneath the Austrides in what are known as "windows." In the Lower Engadine window, schistes lustrés occur surrounded by Grisonide elements, whilst in the Hohe Tauern window there are tectonic elements correlated by Staub with the Monte Rosa and the Dent Blanche Nappes as well as schistes lustrés. (Kober considers that the lowest elements here are homologous with the higher Simplon Nappes.) In the Semmering window, denudation has revealed the Grisonides beneath the Tirolides.

The Grisonides are divided into two major structures, the Campo (VIII.) Nappe and the Err-Bernina (VII.) Nappe, each of which has several digitations in its frontal portion. The lower of the two rests on the Margna (VI.) Nappe, which is homologous to the Dent Blanche Nappe. The Grisonides consist of crystalline cores surrounded by sedimentary rocks, the latter being peculiar in age and facies to each nappe. In the Rhätikon the Grisonides show "schuppen" structure (*i.e.*, slices overthrust one upon another) and parts of them exhibit interesting sedimentary types, which are important in a study of the Prealps. The Tirolides are similarly divided into two major structures, the Oetzal (X.) Nappe and the Silvretta (IX.) Nappe. The latter nappe is the greatest East Alpine structure and, being the lower of the two Tirolide elements, will occur to the north of the Oetzal Nappe in the "root" region, but the sedimentary cover of the latter has been driven over the Silvretta Nappe and forms the northern Limestone zone. The main outcrop of the Oetzal Nappe is in the Mur Alps of Styria, whilst the other forms the Silvretta mountain mass. The northern Limestone zone forms a wide belt from the Rhine-line to Vienna and has the structure of a great pile of overthrust masses of rocks ranging from the Trias to Cretaceous, the dolomite of the Trias being the principal member of the group. North of this zone is the northern Flysch zone, which is the eastern representative of the high Calcareous Alps.

TECTONIC MAP OF ALPS: AFTER STAUB

FROM RUDOLF STAUB'S "TEKTONISCHE CARTE DER ALPEN," BY COURTESY OF THE SCHWEIZ GEOLOGISCHE KOMMISSION, BASEL.

MAP OF THE GEOLOGICAL FORMATION OF THE ALPS, SHOWING THE OUTCROPS OF THE CHIEF TECTONIC ELEMENTS

Austride elements occur west of the Rhine-line, in the Prealps, which lie between the great Swiss plateau and the high Calcareous Alps and between the River Arve and the Lake Thun. The following tectonic elements have been identified in this region:— the External Prealps forming the northern portion and being overthrust upon the Molasse of the great Swiss plateau; and the Internal Prealps on the southern margin. The Internal and External Prealps are probably connected and completely underlie the basin-like structure filled by the higher elements of the Prealps. In these two zones the higher units of the high Calcareous Alps occur. Above the Internal Prealps is the Niesen Nappe (chiefly sandstones and conglomerates), which shows Pennine affinities; whilst above the External zone there are similar sandstones, etc., forming the zone of Gurnigel which is considered by some to represent the Niesen Nappe. The Median Prealps Nappe occurs above the zones mentioned and forms the greater part of the Prealps. Above it are the Simme Nappe and the Brèche Nappe. These structures seem to show Austride affinities, and the association between them and the

Austrides is further established by the occurrence of "Klippen" (*i.e.*, frontal portions of nappes isolated by erosion) which have the character of a connecting link, resting upon the Mesozoic rocks of the high Calcareous Alps in the central Swiss region. According to Argand the "roots" of the Simme Nappe occur in the zone of Canavese, south of the Lepontine culmination. These also are west of the Rhine-line, but they are continuous with the "roots" of the other Austride elements farther east. In the zone of Canavese the Dent Blanche Nappe is "rooted" together with the Austrides, and in consequence of this Kober considers that this nappe must belong to the East Alpine group (Austrides) and not to the Pennine chain.

The "roots" of the Pennine Nappes (the "inner roots") lie in a zone which stretches eastward from near Ivrea, through Locarno. The "roots" of the Austrides are in contact with these but on the south side of them. The nappes are vertical in this zone or even overturned toward the south. To the south again are the Dinaride Nappes. The boundary between the Austrides and the Dinarides

(the Dinaric boundary) passes from the neighbourhood of the Italian Lakes to Meran, then east through the Drau Range to the south-east end of Bacher mountains, where it disappears beneath the Hungarian Plain. The tectonics of the Dinarides are comparatively simple. The term "nappes" is still used here by some authorities to designate the tectonic units; but the latter are very different from the nappes of other parts of the Alps, being essentially thrust masses. The extent of the thrusting is never very large. Moreover the units are not so strikingly different from one another in facies as is the case in other parts of the Alps. Kober recognizes four zones here, the Outer Zone (Adriatic), the Lower Dinaric Nappe, the Upper Dinaric Nappe and the High Dinaric Nappe. The stratigraphy of the Dinaric zone shows an important development of Up. Palaeozoic rocks, Silurian, Devonian, Carboniferous, Permian and Trias. Jurassic, Cretaceous and Flysch are also important in some units. This southern belt of the Alps is noted for its rich development of calcareous rocks. "Klippen" (outliers) of Dinaride elements occur resting upon the Oetzal Nappe in the Mur Alps district. The tectonics of the structures south of the Dinaric boundary show a southward direction of movement. This reverse direction of movement probably indicates one of the latest phases of the Alpine movements. There has been considerable igneous activity in this region, but the intrusions are not all of the same age. The following are affected by Tertiary movements and must therefore belong to an earlier period:—the Kreuz, Iffinger, Brixen, and Riesenferner intrusions. The "Peri-Adriatic Intrusion Zone" (Salomon) contains the following igneous bodies:—Ivrea, Baveno, Bergeller, Adamello, the tonalite of Eisenkappel and the granites of the Bacher mountains. These were not affected by Alpine movements and are, by many authorities, thought to be of slightly later date than those movements.

Main Chain.—Several important mountain groups are situated on one or other side of the watershed of the Alps and form almost independent ranges, connected with the main chain by a kind of isthmus: such are the Dauphiné Alps, the Eastern and Western Graians, the entire Bernese Oberland, etc. The Alps, therefore, are not composed of a single range but of a great "divide," flanked on either side by other important ranges.

Starting from the Col d'Altare or di Cadibona (west of Savona), the main chain extends first south-west, then north-west to the Col di Tenda, though nowhere rising much beyond the zone of coniferous trees. Beyond the Col di Tenda the direction is first west then north-west to the Rocher des Trois Evêques (9,390ft.), just south of the Mont Enchastraye (9,695ft.), several peaks of about 10,000ft. rising on the watershed, though the highest of all, the Punta dell'Argentera (10,794ft.) stands a little way to its north. From the Rocher des Trois Evêques the watershed runs due north though of the two loftiest peaks of this region; one, the Aiguille de Chambeiron (11,155ft.) to the west and the other, the Monte Viso (12,609ft.) to the east of the watershed. From the head of the Val Pellice the main chain runs north-west and diminishes much in average height till it reaches the Mont Thabor (10,449ft.), which forms the apex of a salient, which the main chain here presents towards the west. Hence the main watershed extends east, culminating in the Aiguille de Scolette (11,500ft.) but makes a great curve to the north-west and back to the south-east before rising in the Rochemelon (11,605ft.), a re-entering angle in the great rampart by which Italy is guarded. Thence the direction taken is north as far as the east summit (11,693ft.) of the Levanna, the watershed rising in a series of snowy peaks, though the loftiest point of the region, the Pointe de Charbonel (12,336ft.), stands a little to the west. Once more the chain bends north-west rising in several lofty peaks (the highest is the Aiguille de la Grande Sassièrè (12,323ft.), before attaining the considerable depression of the Little St. Bernard Pass (7,179ft.). Thence for a short way the direction is north to the Col de la Seigne (8,242ft.), and then north-east along the crest of the Mont Blanc chain, which culminates in the peak of Mont Blanc (15,782ft.), the loftiest in the Alps. A number of high peaks crown our watershed before it attains the Mont Dolent (12,543ft.). Thence after a short dip south-east, our chain takes near the Great St. Bernard Pass

(8,111ft.) the general easterly direction that it maintains throughout the Pennine Alps till it reaches Monte Rosa, whence it bends north, making one small dip to the east as far as the Simplon Pass. In the Pennine Alps the main chain maintains a greater average height than in any other part, but, though it rises in a number of lofty peaks, such as the Mont Velan (12,353ft.), the Matterhorn (14,782ft.), the Lyskamm (14,889ft.), the Nord End of Monte Rosa (15,132ft.) and the Weissmies (13,226ft.), yet many of the highest points such as the Grand Combin (14,164ft.), the Dent Blanche (14,318ft.), the Weisshorn (14,804ft.), the true summit or Dufourspitz (15,217ft.) of Monte Rosa itself, and the Dom (14,942ft.), rise on its northern slope and not on the main watershed. The chain between the Great St. Bernard and the Simplon sinks at barely half a dozen points below a level of 10,000ft. Eastward from the Simplon (6,592ft.) through the Lepontine Alps so far as the St. Gotthard (6,935ft.) the divide runs north-east, all the higher summits (including the Monte Leone, 11,684ft., and the Pizzo Rotondo, 10,489ft.) rising on it, a curious contrast to the long stretch just described. From the St. Gotthard to the Maloja (5,960ft.) the watershed between the basins of the Rhine and Po runs east as a whole, though making two great dips towards the south first to near the Vogelberg (10,565ft.) and again to near the Pizzo Gallegione (10,201ft.), so that it presents a broken and irregular appearance. Its highest point is the Rheinwaldhorn (11,149ft.).

From the Maloja Pass the main watershed dips south-east for a short distance, and then east and nearly over the highest summit of the Bernina group, the Piz Bernina (13,304ft.) to the Bernina Pass (7,645ft.) Thence to the Reschen Scheideck Pass (4,954ft.) the main chain is ill-defined, though on it rises the Corno di Campo (10,844ft.), beyond which it runs slightly north-east, past the sources of the Adda and the Frael Pass (6,398ft.), sinks to form the depression of the Ofen Pass (7,523ft.), soon bends north and rises once more in the Piz Sesvenna (10,568ft.). The break in the continuity of the Alpine chain marked by the deep valley, the *Vintschgau*, of the upper Adige is one of the most remarkable features in the orography of the Alps. The chief source of the Adige is the little Reschen lake, which is only 13ft. below the Reschen Scheideck Pass (4,902ft.) and but 5m. from the Inn valley. East of this pass the main chain runs north-east to the Brenner Pass along the snowy crest of the Oetzthal and Stubai Alps, the loftiest point on it being the Weisskugel (12,291ft., Oetzthal), for the highest summits both of the Oetzthal and of the Stubai districts, the Wildspitze (12,382ft.) and the Zuckerhütl (11,520ft.), stand a little to the north.

The Brenner (4,495ft.) is almost the lowest of all the great motor road passes across the main chain, and has always been the chief means of road communication between Germany and Italy. For some way beyond it the watershed runs east over the Hochfeiler (11,559ft.) the highest crest of the Zillerthal Alps. A little farther, at the Dreiherrnspitze (11,500ft.), we have to choose between following the watershed south, or keeping due east along the highest crest of the Greater Tauern Alps. (a) The latter course is adopted by many geographers. The watershed (though not the chief Alpine watershed) continues east through the Greater Tauern Alps, culminating in the Gross Venediger (12,008ft.), for the Gross Glockner (12,461ft.) rises to the south. Our chain bends north-east near the Radstädter Tauern Pass (5,702ft.) and preserves that direction through the Lesser Tauern Alps to the Semmering Pass (3,225ft.). (b) On the other hand, from the Dreiherrnspitze the true main watershed of the Alpine chain dips south, passes over the Hochgall (11,287ft.), the culmination of the Rieserferner group, and then sinks to the Toblach Pass (3,967ft.) but a little east of the great Dolomite peak of the Drei Zinnen (9,837ft.) it bends east again and rises in the Monte Cogliano (9,128ft., the monarch of the Carnic Alps). Soon after our watershed makes a last bend to the south-east and culminates in the Terglou (9,400ft.), the highest point of the Julian Alps, though the Grintovc (8,429ft., the culmination of the Karawanken Alps) stands more to the east. Finally our watershed turns south and ends near the great limestone plateau of the Birnbaumerwald, between Laibach and Görz.

Principal Passes.—The Alps have never formed an impassable barrier. The spots at which they are crossed are called passes and are the points at which the great chain sinks to form depressions. Hence the oldest name for such passes is *Mont* (still retained in cases of the Mont Cenis and the Monte Moro); it was long before this term was especially applied to the peaks of the Alps, which, with a few rare exceptions (*e.g.*, the Monte Viso was known to the Romans as Vesulus), were simply disregarded. The native inhabitants of the Alps were naturally the first to use the alpine passes, but to the outer world these passes first became known when the Romans traversed them in order to conquer the world beyond. For obvious reasons the Romans, having once found an easy pass did not trouble to seek for harder routes. The passes known to them were comparatively few: they are, in topographical order from west to east, the Col de l'Argentière, the Mont Genève, the two St. Bernards, the Splügen, the Septimer, the Brenner, the Radstädter Tauern, the Sölscharte, the Plöcken and the Pontebba (or Saifnitz). The Mont Genève and the Brenner were the most frequented, while it will be noticed that in the Central Alps only two passes (the Splügen and the Septimer) were certainly known to the Romans. The Simplon is first certainly mentioned in 1235, the St. Gotthard (without name) in 1236, the Lukmanier in 965, the San Bernardino in 941. Even the Mont Cenis (from the 15th to the 19th century the favourite pass for travellers) is first heard of in 756 only. In the 13th century many hitherto unknown passes came into prominence, even some of the easy glacier passes. In the Western and Central Alps there is but one ridge to cross, to which access is gained by a deep-cut valley, though often it would be shorter to cross a second pass in order to gain the plains, *e.g.*, the Mont Genève, that is most directly reached by the Col du Lautaret. In the Eastern Alps it is generally necessary to cross three distinct ridges between the north and south plains, the central ridge being the highest and most difficult. The passes which crossed a single ridge, and did not involve too great a detour through a long valley of approach, became the most important and the most popular, *e.g.*, the Mont Cenis, the Great St. Bernard, the St. Gotthard, the Septimer and the Brenner. As time went on the travellers who used the great alpine passes could not put up any longer with the bad old mule paths. A few passes (*e.g.*, the Semmering, the Brenner, the Tenda and the Arlberg) can boast of carriage roads constructed before 1800, while those over the Umbrail and the Great St. Bernard were not completed till the early 20th century. Many of the carriage roads across the great alpine passes were constructed in the 19th century, largely owing to the impetus given by Napoleon. As late as 1905, the highest pass over the main chain that had a carriage road was the Great St. Bernard (8,111ft.). More recently railway lines have been carried over or through the chain—there being the Brenner and Pontebba lines, both over passes, and the Col di Tenda, Mont Cenis, Simplon, St. Gotthard, Lötschen, Arlberg, Albula and Pyhrn through tunnels. There are also schemes for piercing the Splügen and the Hohe Tauern, both on the main ridge. Since the advent of motor-cars several old road-passes have been improved and new ways made.

Glaciers.—Because the Alps were explored and studied earlier than the other mountain systems of the world, the type of glaciation found there has received the name "Alpine Type." It is similar to that of parts of the Himalayas, Andes, Rockies and the mountains of New Zealand but is different from that of Spitzbergen, Greenland, Alaska and the Polar regions (*see GLACIERS*). The main characteristics of the Alpine type consist of an elevated "catchment area" from which valleys pass down to lower altitudes. The highest peaks do not necessarily form the centres from which the largest glaciers radiate, but these latter arise where the topography of the mountain masses is that of numerous depressions and wide hollows separated by rounded snow-capped peaks, as Mont Blanc or by steep-sided frost-eaten peaks and ridges as the Aiguilles. Snow accumulates in these hollows and is compacted into ice which differs in appearance and internal structure from ice formed in the normal way by freezing. It is known as "*névé*" (Fr.) or "*firn*" (Ger.). This ice is forced downward by the weight of the accumulated snow above, or falls down as avalanches into

the valley below, forming the valley glaciers characteristic of the Alps. The boundary between the *névé* and the valley glacier (the *firn*-line) is marked by a change in the character of the surface of the ice. Above the *firn*-line precipitation is greater than melting and so snow covers the surface, but below it the reverse is the case and the ice is exposed. In summer the *firn*-line is quite distinct, but generally some hundreds of feet below the limit of perpetual snow.

It is estimated that there are 1,200 separate glaciers and *névé* fields in the Alps, but many are mere accumulations of snow in small hollows which really form part of larger basins. The largest glacier in the Alps is the Aletsch Glacier which is 16m. long and with its *névé* and catchment area covers an area of over 50sq. miles. The lowest point reached by glaciers varies considerably; it is as low as 3,200ft. above sea-level at Grindelwald, but the height is more often quite 1,000ft. higher than this. The line of perpetual snow lies between 8,000ft. and 9,500 feet. Its exact position varies locally; regions which rise above these limits form centres for the radiation of valley glaciers. The largest of such centres are in the Mont Blanc group, the Bernese Oberland (from Blumlisalp to the Wetterhorn) and in the Pennine Alps (from the Grand Combin to the Mischabel). The main chain boasts of more glaciers and *névé* than the subsidiary chains. Nevertheless, the three longest glaciers of the Alps, the Greater Aletsch (16m.) and the Unteraar and the Viescher (each 10m.), are in the Bernese Oberland. The longest glaciers in the main chain are the Mer de Glace and the Gorner (each 9½m.).

During the Pleistocene Ice Age the whole chain was more than once covered by an ice sheet above which perhaps the main peaks stood out. Penck infers four ice-maxima, Bayer thinks there were only two. One of the intervals, it is generally agreed, witnessed a return of warm temperate conditions. The final retreat of the Pleistocene Ice Sheet proceeded by stages, and it has been suggested there was a serious regrowth of glaciers in early centuries of the last millenium B.C. Each stage was marked by a continuous retreat of the ice front to higher altitudes, no movement or perhaps even a temporary advance occurring in the intervals. During historical times the movement of the fronts has not been very marked. In 1918 a general forward movement was noticed in most Alpine glaciers, the previous great advance commencing in 1818 and finishing in 1822. The smaller glaciers will, of course, show movement more quickly than the larger. This is illustrated in the case of the Aletsch Glacier, which has maintained the same position of its front for many years. In 1823 this glacier suddenly dropped its level (for reasons not understood) causing the level of Lake Märjelen, which is formed by the glacier obstructing the mouth of a tributary stream, to fall.

Lakes and Water Power.—The lakes of the Alps are of several types. (*See LAKE.*) Lakes of the barrier type are formed in various ways, principally by terminal and lateral moraines, in rarer cases by land slides, alluvial fans or a glacier. Lake Zürich shows interesting phases of damming by various moraines; Lake Mattmark is formed by a lateral moraine; Lake Märjelen is a classic example of a glacier acting as a dam. Examples of lakes of tectonic origin are Lake Joux, in the Jura region, which occurs in a syncline, and Lake Fählen near Säntis. Lakes formed by the solution of calcareous rocks are of two types: the "polje" and the "doline" types. Frequently the depressions occupied by these lakes were the sites of former glaciers, as proved by the lining of glacial clay which the lakes now possess. Lakes of these types are quite frequent in the limestone areas and examples are Lakes Dauben, Mitten and Seewli (the latter also being in a corrie). Lakes in depressions in water-bearing strata occur on moraines or on fluvio-glacial material. No rivers feed them and they have no visible effluents. Examples of the formation of two small lakes from a large one by a lacustrine delta are the lakes of Thun and Brienz and of Silser and Silvaplana.

In recent years the Alps have become a most important source of hydro-electric power for industry, railway transport and lighting, and the amount of coal used is diminishing. Nowhere, even in the limestone districts, is the amount of water so small as to warrant the exclusive use of coal or other fuels. As the water is
